ACRIFLAVINE AS A URINARY ANTISEPTIC

BY ERIC W. ASSINDER, M.D. Birm.

DIRECTOR OF THE VENEREAL DISEASES DEPARTMENT,
THE GENERAL HOSPITAL, BIRMINGHAM

ACRIFLAVINE has been used as a general and urinary antiseptic for some years; its action is directly antiseptic, not depending upon excessive acidity or alkalinity of the urine, although higher antiseptic values are obtained undoubtedly in alkaline than in acid urine. In the venereal diseases department of the General Hospital, Birmingham, it has been used intravenously in the routine treatment of acute gonorrhœa in 4985 cases. Numerous other so-called urinary antiseptics have also been used but in none has the improvement been so great as with acriflavine.

The application of this drug has not been confined to gonococcal infection; many cases of *Bacillus coli* infection of the urinary tract have also been treated successfully.

Similar reports have been made from time to time by other observers. In 1921 Davis¹ stated that "by a study of 204 aniline dyes, with only two (proflavine and acriflavine) was it possible to demonstrate the secretion of antiseptic urine following intravenous injection." In 1926 Jausion and Vaucel² claimed very successful treatment of gonorrhœa with intravenous acriflavine alone. Further, in 1932 Davis and Sharpe³ said that "acriflavine exerts an antiseptic action in normal urine which is uniform and consistent to a surprising degree." They also found that alkalinity is "quite essential for consistent and dependable results."

It should be stated that acriflavine as a urinary antiseptic must not be looked upon as the sole weapon in treatment; one must realise that the urinary tract is not a simple tube, but one into which there are many glandular openings, especially the ducts of the prostate and urethral glands. Obviously it is sometimes impossible to reach the real site of infection with a urinary antiseptic, although one may cleanse the surface of the tract temporarily, and it seems desirable, therefore, in all cases of urinary infection to attempt to increase a patient's resistance to a particular organism by, for example, vaccine treatment.

GONORRHŒA

As a routine all cases of acute gonorrhœa in the male have had intravenous injections of 2-4 c.cm. of a 2 per cent. solution of acriflavine in sterile distilled water. Ten such injections have been the standard course (one injection being given every second or third day). The patient has been instructed not to take large amounts of fluid, so that a higher concentration of acriflavine shall be obtained in the urine. The necessity for this precaution is well brought out by the experiments of Miller and Chu.⁴ (In accordance with what has been stated above, supplementary treatment, such as vaccine, irrigation, and potassium citrate grs. 60 t.d.s. to ensure an alkaline urine, has also been given.)

The intravenous route has always been chosen in order to get the immediate and maximum effect upon the urinary tract. In my opinion, one does not get such good results with acriflavine by mouth, and it seems more than probable that a large part of the acriflavine given by mouth will not be excreted through the kidneys at all.

Results.—In the 4985 cases of acute gonorrhœa which have been given acriflavine, perhaps the most noticeable feature has been the short duration of the urethral discharge; as a rule the discharge ceases in 7-10 days, which is very much less than is usual in the average case treated by irrigation alone. If the posterior urethra is already affected, acriflavine, which is being continuously excreted into the bladder, helps to clear the cystitis; while if the posterior urethra is not affected, the acriflavine apparently protects it.

It is obviously not possible with such a large number of cases to give accurate percentages of cure within a particular time; for many of the patients will not attend for tests of cure. But the very decided impression has been that the duration of the actual infection, like the duration of the initial discharge, has been much shortened by acriflavine.

B. COLI INFECTIONS OF THE URINARY TRACT

It is quite common for cases of *B. coli* infection to reach a venereal diseases clinic, sent up as possible gonococcal infections, perhaps because of epididymitis or frequency of micturition. Table I. shows the results in consecutive cases of bacilluria treated with acriflavine and also with an autogenous vaccine.

TABLE I

B. coli Bacilluria treated with Acriflavine and Autogenous Vaccine

Case.	Duration of urinary trouble before treatment.	Number of injections of 2 per cent. acriflavine.	Clinical result.	Pathological result (cultural).
1	2 months.	8 × 4 c.cm.	Cured.	Cured.
2	4 "	10 × 4 "	"	"
3	10 days.	8 × 3 "	"	"
4*	3 months.	8 × 4 "	"	<i>B. coli</i> still present.
5	3 "	10 × 2 "	"	Cured.
6	1 year.	10 × 4 "	"	"
7	5 months.	20 × 4 "	"	"
8	3 weeks.	30 × 4 "	No symptoms. Cured.	<i>B. coli</i> still present.
9	2 days.	8 × 4 "	Cured.	Cured.
10*	7 years.	28 × 4 "	Failure.	<i>B. coli</i> still present.
11	3 weeks.	8 × 4 "	Cured.	Cured.
12	4 days.	6 × 1 "	"	"

* Case 4 developed jaundice; no more acriflavine given.
* Case 7.—*B. coli* still present after first course of ten injections.
* Case 10.—Patient relapsed after being clear of *B. coli* in urine and clinically well.

These results are very strong evidence of the value of acriflavine, and compare favourably with those obtained by the use of a ketogenic diet⁵ or mandelic acid.⁶

EXPERIMENTAL

Acriflavine can be showed to have an extraordinarily high antiseptic value in regard to the gonococcus. I find that a dilution of 1 in 20,000 will kill the gonococcus in fifteen minutes. Its action upon such organisms as *B. coli* is, as one would expect, much less; some strains are only killed in thirty minutes in a dilution of 1 in 200.

It seems reasonable to expect that the urine of a patient who is receiving an antiseptic for a urinary infection should show definite antiseptic properties. In order to test this property, the urine of two patients was examined:—

- (a) A patient who was given 3 c.cm. of acriflavine (2 per cent.) intravenously and passed urine within half an hour.
(b) A patient who had been on hexamine grs. 10 and ammonium chloride grs. 15 t.d.s. for a week.

Four cubic centimetres of each of these urines were added to 24-hour cultures of gonococci; the suspensions of these gonococci in the urines to be tested were then put in the incubator at 37° C., and to each was added three drops of serum to ensure growth if antiseptic action had not taken place. Subcultures were then made at intervals of one, two, three, and four hours. The results are seen in Table II.

TABLE II

Growth of Organisms in Urine of Patients receiving (a) Acriflavine and (b) Hexamine and Ammonium Chloride

Hours	1	2	3	4
Urine A	+	-	-	-
Urine B—pH 5.4 (after addition of serum) ..	+	+	+	+

+ = Growth of gonococci } after 48 hours' incubation.
 - = No growth of gonococci

The tests were repeated on other patients with the same results and appear to confirm the clinical findings of the value of acriflavine as a urinary antiseptic.

PREPARATION OF ACRIFLAVINE

For nearly five years the acriflavine used in the above series was very satisfactory from a tolerance standpoint. There were a few cases of dermatitis on parts exposed to sunlight, such as face and hands, and also an occasional case of toxic jaundice; this was in accord with the findings of Jausion and Vaucel² and many others. In 1932-33, however, jaundice began to occur with great frequency, and it was quite obvious that it would not be possible to continue with the drug, at any rate in the same dosage as previously, although it seemed to be of great value in the treatment of urinary infections. Other observers were obviously troubled in a similar way, and Hughes and Birch⁷ in 1933 stated that they had abandoned flavine therapy owing to toxic effects. Correspondence in THE LANCET in 1931⁸ suggested that the acriflavines which were being used were not chemically identical.

Such contradictory experiences forced us to the conclusion that the acriflavine used in 1928 differed in some important way from that used in 1933, and in 1933-34 the products of different firms were tried. The prevalence of jaundice nevertheless continued.

In February, 1935, Imperial Chemical Industries Ltd., Dyestuffs Group, were asked to investigate the matter, and they have succeeded in supplying an acriflavine which is apparently non-toxic.* Since June, 1935, 300 patients have been given this new product intravenously according to the method described above, and in only 2 cases has there been any evidence of liver damage: in these there was transient jaundice for 48 hours only, and this may have been due to other causes. Every case has been investigated for signs of hepatic damage, and before each injection the urine has been examined for urobilinogen; this has been conspicuously absent whereas in 1933 it was found with great regularity.

In my opinion, patients who are receiving acriflavine should always be tested for the presence of urobilinogen in the urine and use of the drug should be discontinued if it is found.

* This preparation, Acriflavine (Intravenous), may be obtained from The British Drug Houses Ltd.

INBORN AND FAMILIAL TENDENCY TO THE DEVELOPMENT OF HEPATIC CIRRHOSIS*

By F. PARKES WEBER, M.D. Camb., F.R.C.P. Lond.
 SENIOR PHYSICIAN TO THE GERMAN HOSPITAL, LONDON

CASES of hepatic cirrhosis in children, not due to alcohol or congenital syphilis or any known cause of cirrhosis, are usually regarded as the manifestation or one of the manifestations of a congenital-developmental disease, and the occasional familial incidence of cirrhosis has often been adduced in support of this view. In this paper I shall shortly discuss the data in favour of there being an inborn tendency to hepatic cirrhosis (a congenital tissue or organ inferiority of the liver, as Prof. Brouwer would say, destined to manifest itself by obvious changes in postnatal life, with or without known exciting causes), and shall arrange my remarks under two headings: (I.) examples of the familial incidence of hepatic cirrhosis, in which the cirrhosis has not been due to any known exciting cause, such as alcohol or syphilis, or in which an inborn familial tendency to the disease may be presumed because an exciting cause such as alcohol, though present in one of the affected members of the family, was absent in others; (II.) examples of hepatic cirrhosis accompanying and probably constituting a part of acknowledged diseases of the congenital-developmental class.

But first I must explain what I mean by *diseases of the congenital-developmental class*. Under congenital-developmental diseases and abnormalities I include all truly inborn abnormalities and constitutional diseases, whether obvious at birth or manifesting themselves later at various ages. Amongst the more easily recognised ones are: hæmophilia; hæmolytic (acholuric) jaundice, and some other familial abnormalities of the blood (and hæmopoietic system); alkaptonuria, congenital porphyrinuria, and other inborn abnormalities of metabolism, such as Gaucher's disease, the Niemann-Pick disease, amaurotic family idiocy, familial cutaneous xanthomatosis, the Hand-Schüller-Christian lipid-granulomatosis, von Gierke's hepatomegalic glycogen-storage disease, &c.; renal glycosuria (apparently harmless in itself); familial optic nerve atrophy and other diseases, dysplasias and dysbiotrophic conditions in which the eyes are affected; numerous hereditary diseases and dysplasias of the skeletal (bone and cartilage), muscular, vascular, and nervous systems; and many minor conditions, including inherited abnormalities of the skin and its appendages; food-idiosyncrasies and allergic peculiarities. It is almost certain that many

* Some remarks on this subject, which are here amplified, were made by Dr. Parkes Weber in the discussion on Prof. B. Brouwer's paper on the Spleen, the Liver, and the Brain, at the meeting of the section of neurology of the Royal Society of Medicine on Jan. 16th, 1936.

diseases, which are rarely obviously inherited—such as hypertrophic pyloric stenosis (which may occur occasionally in twins or recurrently in more than one child of the same parents) and Hirschsprung's megacolon congenitum and aortic isthmus stenosis—also really belong to the group under consideration.¹ All inborn constitutional diseases belong to the congenital-developmental group, even when their manifestations are delayed till long after birth, till puberty, middle age, or even later. It is because the manifestations are often delayed till long after birth that I prefer to speak of this group of diseases as the congenital-developmental group, and not as the congenital group.

Known hereditary or familial incidence may often be absent in diseases and abnormalities of the congenital-developmental class, but its occasional presence is sufficient to stamp the disease or abnormality as belonging to the class. Thus, the puzzling disease "lipodystrophia progressiva" apparently belongs to the class and seems to be a "dysbiotrophy" (if I may use the term, instead of "abi-trophy" of Gowers) of the subcutaneous fat over the head and upper part of the body, chiefly affecting females. L. Barraquer-Ferré² has lately narrated the case of a female whose mother and maternal grandmother were likewise affected. The disease, though potentially present at birth, may be "delayed" in its appearance long enough to allow of a female not being prevented by her shrunken death's-head-like face from finding a mate. Some would probably prefer to express themselves by saying that the lipodystrophia was potentially present at birth as a congenital tissue inferiority (Gewebsminderwertigkeit).

I.—EXAMPLES OF THE FAMILIAL INCIDENCE OF HEPATIC CIRRHOSIS, NOT DUE TO ANY KNOWN EXCITING AGENT OF THE DISEASE

Various cases of familial hepatic cirrhosis have been published.

At the Royal Society of Medicine (section for the study of disease in children) in February, 1934, Prof. F. Langmead³ demonstrated cirrhosis of the liver with splenomegaly in three brothers, aged 9, 11, and 13 years respectively. In the boy, aged 11 years, the diagnosis was subsequently confirmed by microscopic examination ("biopsy"), which showed typical multilobular cirrhosis of the liver. Langmead referred to Byrom Bramwell's account (1910) of a family with hepatic cirrhosis.⁴ Byrom Bramwell's patient, a boy, aged 9 years, had ascites, œdema, jaundice, fever, and a large liver, and the necropsy showed typical "hob-nailed" cirrhosis. Three other members (girls) of the family of seven apparently died from hepatic cirrhosis. Langmead also mentioned J. Szanto's⁵ three cases of multilobular cirrhosis of unknown origin, with splenomegaly, in a family of ten. In one of these cases the diagnosis of hepatic cirrhosis was confirmed by necropsy (a boy, aged 15 years) who likewise had genital hypoplasia.

F. J. Poynton and W. G. Wyllie⁶ in 1926 described two cases of congenital familial hepatic cirrhosis of unknown ætiology in a brother and sister, aged 9 years and 4 years respectively, but the diagnosis of von Gierke's hepatomegaly (hepatomegalia glycogenica) was subsequently suggested.⁷

In 1903 I recorded the necropsy on a girl, aged 14 years, with biliary cirrhosis ("Hanot's disease") of the liver.⁸ Her sister was said to have died at the age of 19 years with similar symptoms. J. Dreschfeld⁹ met with hypertrophic hepatic cirrhosis in two brothers, one of them was a drinker and the other temperate. Sir William Osler¹⁰ mentioned two

brothers in America affected with Hanot's cirrhosis. Boinet¹¹ wrote of a family in which the father and two children had biliary cirrhosis (Hanot's type) and three other children had enlarged spleens. J. Finlayson¹² spoke of three brothers and a sister, two of whom had cirrhosis of Hanot's type; another had enlargement of the liver and spleen, with icterus, and the remaining one had slight jaundice. Hasenclever¹³ recorded an instance of three members of one family, a boy and two of his sisters, having typical hypertrophic biliary cirrhosis.

II.—EXAMPLES OF HEPATIC CIRRHOSIS ACCOMPANYING AND PROBABLY CONSTITUTING A PART OF ACKNOWLEDGED DISEASES OF THE CON- GENITAL DEVELOPMENTAL CLASS

Progressive lenticular degeneration (Kinnier Wilson's disease).—Wilson's disease is a chronic progressive degeneration of the lenticular nuclei of the brain combined with a cirrhosis of the liver, which has been usually latent during life and first discovered at the post-mortem examination. Familial incidence in this rare disease has been emphasised by Wilson himself, as well as by later authors. The evidence seems to me to point to the disease being most probably a combined "dysbiotrophy" of the lenticular nuclei and the liver, and the hepatic constituent of the combined condition in some cases does give rise to obvious clinical symptoms so as to be recognised as a form of familial cirrhosis even during life.¹⁴ In some cases the lenticular nuclei or the liver may be only slightly affected, but it seems very unlikely that any of the above-mentioned cases of familial hepatic cirrhosis in children were of the nature of incomplete Wilson's disease with the liver only affected.

Hæmochromatosis.—The occurrence of hepatic cirrhosis ("pigmentary cirrhosis of the liver") as a part of hæmochromatosis or "bronzed diabetes" is too well known to need insistence. The site of the greatest visceral changes varies in different cases, and the characteristic liver changes may occur even without very marked cutaneous pigmentation. The occasional familial incidence of the disease has been pointed out by J. H. Sheldon,¹⁵ R. D. Lawrence,¹⁶ and others, so that hæmochromatosis must be classed amongst the rare inborn abnormalities of metabolism, such as alkaptonuria, pentosuria, cystinuria, congenital porphyrinuria, the inborn abnormalities of lipid metabolism, &c., which I have above referred to. Indeed, a special analogy may be pointed out in regard to von Gierke's hepatomegalic glycogen-storage abnormality, in as much as in the latter disease different viscera (e.g., the heart) may be specially involved in different cases.

Erythræmia.—Though I think that erythræmia of the Vaquez-Osler type is, like the leukaemias, due to a neoplastic change in the bone-marrow, a familial incidence of the disease has been reported in quite a number of cases.¹⁷ It may be presumed to develop (under the action of unknown agents) in individuals having an inborn constitutional predisposition. Hepatic cirrhosis is a recognised though only occasional complication of erythræmia, and seems in some cases to occur independently of any special agent such as phenylhydrazine, which may have been used in the treatment.¹⁸

Telangiectasia of the Osler type.—Very many valuable papers have been written on this disease, including regular monographs with copious bibliographies, by H. I. Goldstein, who was, I believe, the first to call it the "Rendu-Osler disease," by which name it is now known in France. In many cases, though

in far from all, there has been striking hereditary incidence. I was fortunate enough to be able to describe a typical familial example in 1907¹⁹; and in 1924²⁰ I alluded to the possible analogy and association of the telangiectatic condition of the skin and mucous membrane of the nose and mouth with certain hæmorrhagic telangiectatic conditions in the stomach, intestines, kidneys, or lungs. In fact, it is quite possible that in rare cases the typical cutaneous telangiectases may be altogether absent. Very few complete post-mortem examinations have been published, but recently Ludo van Bogaert and J. H. Scherer²¹ found hepatic cirrhosis present in a typical familial case of the Rendu-Osler type of telangiectasia. From what I remember of the progress of the patient I described in 1907 there may well have been visceral disease and perhaps hepatic cirrhosis present at the end. I have been told of an as yet unpublished case in which hepatic cirrhosis was found at the post-mortem examination; so it was also in a remarkably atypical case, the liver and spleen from which were recently (Jan. 13th, 1936) demonstrated by Mr. R. Davies-Colley at the Medical Society in London. The telangiectasia in this disease must be regarded as due to a congenital-developmental dysplasia of the small blood-vessels, potentially present at birth, though often not manifesting itself by obvious changes till after puberty. What is the relationship of the hepatic cirrhosis, when present? Is it the result of an associated developmental dysbiotrophy of the liver—i.e., a congenital tissue or organ inferiority in the sense intended by Prof. B. Brouwer and others? The subject is complicated by the well-known fact that in advanced or active hepatic cirrhosis there is a tendency for the patient to develop cutaneous telangiectases on the face and hands, notably those of the spider-like type, as I have had occasion to observe.

MODERN VIEWS ON HYPERTROPHY OF THE PROSTATE

By PAUL NIEHANS, M.D. Zürich

SURGEON AND UROLOGIST (SWISS MEDICAL FEDERATION),
CLARENS-MONTREUX, SWITZERLAND

THE prostate is a complex gland situated beneath the orifice from which the bladder is emptied and including the prostatic sinus (uterus masculinus). It is composed of tubular-gland tissue embedded in a stroma of connective tissue and unstriated muscle-fibres. The prostate increases in size with age, and may hinder the evacuation of the bladder and even lead to retention of urine.

In adenoma there is an increase in the glandular tissue and the prostate is enlarged and soft. In myoma, muscular tissue predominates. In fibrous degeneration the prostate is of a firm consistence and not always enlarged. In hypertrophy these three tissue elements are met with in varying proportions.

According to the latest statistics, about a third of men aged 60 years and upwards suffer from the prostate and for a long time treatment has been sought to cure or relieve them.

Historical

The first description of hypertrophy of the prostate dates from the sixteenth century. On the ground that hypertrophy of the prostate is a manifestation of old age closely related to the sexual function, surgeons have long endeavoured to cope with it through the medium of the genital system. In 1884 Lannois, in France, suggested castration, but although the clinical results were satisfactory (Burkhard claimed success in 69.2 per cent., Cabot 83.6 per cent., and White 87.2 per cent.) the psychological reaction and ensuing cachexia were so alarming that the succeeding generations of surgeons abandoned this method of treatment. Only in veterinary surgery is hypertrophy of the prostate dealt with by means of castration. Unilateral castration (Albarran, Motz, Pavone) does not lead to any improvement. Harrison in 1893 substituted for castration section of the vasa deferentia, but without obtaining any results. Later Bier, also unsuccessfully, ligatured the vessels leading to the testicle.

As a result of advances in surgical technique, prostatectomy became at the beginning of the present century the routine treatment of prostatic obstruction, and for a time interest in other methods of treatment was lost. It was revived when Romeis reported a marked reduction in the size of the prostate of a man of 68 following the implantation of the testicle of a young man of 22. Since then the close connexion between prostatic hypertrophy of old age and diminution in the internal secretion of the testicle has been confirmed by many observations on animals.

Experimentally, Steinach succeeded in greatly increasing the internal secretion of the testis by blocking the external secretion, but when bilateral ligature of the vas deferens was applied to prostatic enlargement the results were negative. In 1927 I endeavoured to influence prostatic hypertrophy by ligature of the efferent ducts where they emerge from the testis at the level of the head of the epididymis. This produces the maximum increase in the internal secretion of the testis (Steinach). The attempt was more successful, the size of the prostate being diminished in the majority of cases.

In 1933 Landau discovered in cats a constant sympathetic ganglion situated in the connecting capsule surrounding the efferent ducts in the head of the epididymis. This corresponds to the point where the vasa deferentia penetrate the posterior surface of the testis and is the site of my ligature. Nicod found a ganglion in man at the same point. Landau and Heitz-Boyer are both of the opinion that the action of the ligature on the prostate is of a reflex nature, while I¹ believe it to act through the endocrine system.

In 1933 Laqueur and van Cappellen published the results obtained in hypertrophy of the prostate by daily injections of 4–20 units of testicular hormone (Hombreol). In the same year Lacassagne administered 500 units a week of the hormone of the female sex gland (œstrin) to male mice for a period of five months and observed a considerable development of the posterior lobe of the prostate, retention of urine, and secondary hydronephrosis. His observations were confirmed in 1934 by Burrows and Kennaway. Lacassagne and de Jongh also made the interesting observation in 1933 that injections of benzoate of folliculin (œstrin) in young mice, in normal adult mice, and castrated adult mice produced a canceroid epithelial proliferation of the posterior lobe of the prostate, which proved fatal in about six weeks. In 1934 Courrier and Gros asserted that they found marked enlargement of the prostate and seminal vesicles in monkeys treated with folliculin and at the same time an extraordinary development of the unstriped muscle of these organs. In the following year there appeared very interesting articles on the enlargement and alteration of the prostate and seminal vesicles obtained by injecting œstrin into monkeys (Parkes and Zuckerman) and into rats (Laqueur and de Jongh).

Experimental Work on Animals

The fact that hypertrophy of the prostate has been observed in monkeys, dogs, and rats has made it possible to throw light on the subject by means of animal experiments. Long ago John Hunter proved that when castration was carried out in young animals the prostate did not develop, and that after the operation in adult animals it atrophied. Subsequent work has shown that the prostatic secretion stops 53 days after removal of the testicle (Gley, Pézard). The same occurs after a severe lesion of the testicles produced by radium or X rays. When Lower caused anæmia of the testicles by ligature of the arteries he obtained not only a pronounced degeneration of the tubular elements and the interstitial cells, but also a secondary atrophy and sclerosis of the prostate.

All these experiments show that the prostate atrophies and degenerates as soon as the influence of the testicles is removed by castration, by the action of radium and X rays, or by the cutting off of the blood-supply. Lower found that when he subjected the sex glands of rats or dogs to the influence of small doses of radium or X rays the testicles underwent a 50 per cent. reduction in size and weight, the tubules being completely destroyed, but the interstitial cells of Leydig which are more resistant to radiation increased in number. Associated with these changes there occurred an enlargement of the prostate and seminal vesicles. Exactly the same results could be obtained from bilateral operative cryptorchism, that is to say, returning the testicles into the animal's abdomen.

These two experiments prove that destruction of the germinal epithelium and proliferation of Leydig's cells lead to hypertrophy of the prostate. After the vasa deferentia of rats and dogs had been ligatured without damaging the blood-vessels Lower reported that the testicles, prostate, and seminal vesicles showed no change after several months' observation. He therefore concludes that occlusion of the vas deferens does not have any influence on the testicles or prostate.

Steinach, on the other hand, claimed that vasoligature enabled an old animal which had previously micturated with difficulty to empty its bladder, and Slotopolsky stated that after Steinach's ligature II. the old germinal epithelium disappears but is replaced by a newly formed germinal epithelium. From this we can infer that the renewal of the germinal epithelium and reabsorption of its secretion by the circulating blood are followed by a shrinkage of the hypertrophied prostate. A variety of hormones has been used experimentally on animals in order to study their action on the prostate. Whilst research on this subject is still incomplete, the most important results may be summarised as follows:—

I

Influence of the Male Hormone on the Development, Preservation, and Shrinkage of the Prostate

It is known that there are many female hormones and to-day it is admitted that there are also many male hormones. According to McCullagh the male sex gland secretes two hormones:—

(a) A fat-soluble hormone, probably secreted by the interstitial cells of Leydig, which stimulates the development and function of the accessory sex glands including the prostate.

(b) A water-soluble hormone, supposed to be produced by the germinal epithelium, which exerts an inhibitory action on the anterior lobe of the pituitary and the production of prolactin which retards the development of the prostate.

Further, there has been found in the urine of men and even women a male hormone (androstenediol) which, according to Laqueur, is not identical with the hormones of the testis (androsterone) and is chiefly responsible for the growth of the cock's comb in fowls.

II

Influence of the Female Hormones, in particular the Estrogenic Hormone (Folliculin), on Changes in the Prostate

The female follicular hormone (folliculin, œstrin) is normally present just as well in the male as in the female.

In the mouse, small doses of follicular hormone cause typical signs of growth, not only of female organs like the vagina, uterus, tubes, and mammae, but also of the male organs—prostate, seminal vesicles, and ampullæ of the vasa deferentia. By increasing the dose of folliculin the quantitative physiological balance between the male and female hormones is upset on the female side and pathological tissue proliferations appear in the prostate, seminal vesicles, and ampullæ of the vasa deferentia. There is an extensive increase in the unstriped muscle which becomes thickened; at the same time connective tissue and proliferations showing keratinisation appear in the posterior part of the prostate and hinder micturition, so that de Jongh always found the bladder distended in the male mouse, and in rats and guinea-pigs treated with Menformon the seminal vesicles were ten times as large.

The proliferation takes place chiefly in the posterior region of the prostate, which corresponds exactly to the group of glands which develops spontaneously in old men, causing hypertrophy of the prostate (de Jongh). If the injections of menformon are stopped the prostate shrinks completely in mice in three days' time (de Jongh).

Substances like benzoylate of menformon or benzoate of folliculin are even capable of causing growths similar

¹ Schweiz. med. Woch., 1934, lxiv., 557.

to cancer in the posterior part of the prostate (see results obtained by Dodds, Lacassagne, de Jongh). It is therefore possible to start a pathological new growth in the prostate with a female hormone.

All these changes were absent when de Jongh administered both male (hombreol) and female (menformon) hormones together. The prostate was unaltered.

III

Influence on the Prostate of the Hormone of the Anterior Pituitary Lobe: Prolan

Lower, working with sexually immature rats, succeeded in obtaining premature development of the sex glands, prostate, and seminal vesicles by administering prolan B, the hormone of the basophil cells of the anterior pituitary lobe. In adult animals he obtained hypertrophy of the prostate (adenoma) and proliferation of the seminal vesicles by the same means. Extracts of the anterior pituitary lobe were found to be just as active as extracts of the urine of pregnant women.

On the other hand, Engle and Smith found that removal of the anterior pituitary lobe in young rats checked the development of the gonads, prostate, seminal vesicles, and Cowper's glands.

Free secretion of the sex glands inhibits the effect of prolan and for this reason the prostate develops up to puberty and again after 50. Decrease in the quantity of hormone from the sex glands stimulates the secretion of prolan and consequently leads in advancing age to hypertrophy of the prostate.

The loss of the sex glands (castration) is followed by hypertrophy of the anterior lobe of the pituitary,² the cells of which become rapidly exhausted by the excretion of prolan. This secretion though temporarily increased loses all action on the prostate, for, according to the majority of authors, prolan does not act directly on the prostate but indirectly through the medium of the sex glands.

Lower anastomosed the blood-vessels of a rat recently castrated with those of a normal rat. Although the pituitary of the normal rat showed no alteration, the sex glands, prostate, and seminal vesicles were hypertrophied (by the action of the hypertrophied anterior lobe of the pituitary of the castrated animal). These changes only occurred after ten days. Thirty days later the prostate had increased 40 per cent. in size and weight and was composed chiefly of gland tissue (adenoma).

The same results were obtained by injections of the hormone secreted by the basophil cells of the anterior lobe of the pituitary.

In old age, which may be regarded as Nature's method of performing a gradual, incomplete, and discreet castration, the hormone of the sex glands diminishes imperceptibly so that the pituitary has plenty of time to produce its prolan and evoke hypertrophy of the prostate.

The above results may be summarised as follows: Male hormone stimulates the normal development of the prostate. Female hormone produces the formation of fibromyoma of the prostate, and benzoate of folliculin a proliferation of the pavement epithelium of the prostate. Basophil hormone of the anterior lobe of the pituitary (prolan) gives rise to prostatic adenoma.

Prostatic Enlargement in Man

In man also the hormone of the male sex glands regulates the development, preservation, and functions of all the accessory glands, including the prostate. The human prostate attains its normal size at puberty equally with the growth of the testicles and the development of the secretion of the interstitial cells of Leydig. At the onset of the activity of the germinal epithelium the development of the prostate ceases so that the gland remains stationary from puberty

to the sixth decade. From the age of 50 the testes become smaller and softer. While the number of the interstitial cells of Leydig remains unaltered, the secretion of the germinal epithelium and with it the production of spermatozoa gradually diminishes and perhaps is stopped completely. At the same time the prostate renews its development.

If the secretion of the interstitial cells of Leydig is normal the prostate is developed by puberty and keeps within normal limits as long as the secretion of the germinal epithelium is sufficiently plentiful. If the secretion of the interstitial cells of Leydig is lacking the prostate cannot develop. This is the reason why hypoplasia of the prostate is met with in hypoplasia and anomalies of the testicles (Kaufmann) and atrophy of the prostate follows loss of the testicles. Lower found the prostate atrophied, small, fibrous, and hard in ten eunuchs in whom he was not able to demonstrate the presence of the male hormone in the urine. The relation between the testes and prostate is therefore unquestionable.

The prostate is also under the control of the hormone of the basophil cells of the anterior pituitary lobe. When with advancing age the secretion of the germinal epithelium diminishes and gradually dries up the pituitary endocrine centre seeks the aid of prolan to re-establish the function of the genital glands. But a powerful and prolonged action of prolan takes place indirectly—probably through the medium of the cells of Leydig—and promotes the formation of prostatic adenoma. The increased secretion of prolan begins as soon as it is no longer inhibited by an adequate secretion from the germinal epithelium, and continues until the basophil cells of the pituitary are gradually exhausted and replaced by eosinophil cells.

The female follicular hormone also influences the prostate. The follicular hormone is present in the testes and male urine. It stimulates the growth and normal development of the generative system, within the normal physiological limits of its action, together with the male hormone. In the male it is balanced by the hormone of the germinal epithelium, in the female by the hormone of the corpus luteum. Each hormone has its own sphere of action; thus according to de Jongh the follicular hormone controls: (a) In the female genital system, the muscular tissue of the vagina, uterus, and tubes; it induces the growth of pavement epithelium of the vagina and cervix uteri and finally the development of the breasts. (b) In the male, the plain muscle of the prostate, seminal vesicles, and vasa deferentia, together with the connective tissue of their ampullæ, the pavement epithelium³ of the prostate, and the efferent ducts of the seminal vesicles. As de Jongh so aptly puts it: the female hormone produces "a female rut in the male prostate"; the proliferation of the epithelial, muscular, and connective tissue cells of some parts of the prostate leads to its hypertrophy.

In old age the secretion of the sex glands in man is reduced by half (Lower),⁴ while the female hormone is maintained (Laqueur). In this way the physiological equilibrium between the testicular and follicular hormones is upset and the female hormone increases its effect. This accounts for the activity in the prostate, with neoplastic formations at the time of the male climacteric. The secretion of the interstitial

³ The columnar epithelium of the prostate is developed under the influence of male hormone (Lacassagne).

⁴ This increase in size is explained by considering that after castration, the inhibitory action of the sex glands on the basophil cells ceases to have effect as soon as the activity of the anterior lobe of the pituitary becomes increased.

² Normally a man passes 10–24 units of male hormone in the urine in 24 hours. By noting the elimination of hormone in the urine it is possible to tell exactly when an abundant secretion of male hormone becomes much diminished.

cells of Leydig being no longer balanced by that of the germinal epithelium, the prostate enlarges. At the same time there is a rise in the prolan circulating in the blood, which in turn, by stimulating the secretion of the cells of Leydig, leads to hypertrophy of the prostate. If there be a predominance of follicular hormone over male hormone, the prostate hypertrophies and degenerates.

From a consideration of the rôle which these hormones play in the development of the prostate we can conclude that:—

(1) The normal secretion of the interstitial cells of Leydig contributes to the normal development of the prostate.

(2) The pituitary prolan as well as the secretion of Leydig's cells if excreted for a considerable time in increased amounts produces adenoma of the prostate.

(3) An excess of follicular over male hormone leads to the formation of a fibromyomatous prostate.

All these typical alterations of the prostate, which vary in type and degree, can only occur if there be a shortage of hormone from the germinal epithelium. Hence de Jongh's dictum "the testicle protects us from pathological changes in the prostate."

Treatment

If in old age we could augment the internal secretion of the sex glands, especially that of the germinal epithelium, not only would the increased output of prolan be stopped but the physiological balance between male and female hormones would be re-established and the prostatic enlargement reduced. With this end in view the following methods of treatment have been used:—

(1) Injections of male hormone (Laqueur, van Capellen).

(2) Transplantation of testicles of adults (Romeis).

(3) Steinach's ligature II., diversion into the blood stream of all the secretion from the germinal epithelium (Niehans).

Treatment by means of hombraol consists in giving injections of 1 c.cm. of oil of hombraol once or twice daily for three weeks. Laqueur and van Capellen claim that by this method improvement is maintained in some cases for six months. For information on the subject of treatment by means of transplantations of the testes the work of Romeis should be consulted.

In 1928, in a prostatic case aged 69, I applied an inter-epididymo-testicular ligature such as had been advocated by Steinach in order to enhance the endocrine function of the sex glands and bring about rejuvenation. The result was surprisingly good, not only with regard to the general improvement in the patient's condition but also to the effect on the prostate. I showed this case in Montreux in 1928 at the Swiss Surgical Society. The ligature between the testicle and the head of the epididymis closes the efferent ducts through which the external secretion of the testicle escapes, with the result that the hormone of the germinal epithelium as well as the hormone of the interstitial cells of Leydig pass through the pores of the albuginea into the numerous veins which surround the testicle and thus gain the general circulation. This brings about a rejuvenation of the enfeebled organism in the sense that the old cells are reabsorbed and young cells formed. Further it inhibits the abnormal development of the prostate by reducing the hypersecretion of prolan and by re-establishing the physiological balance between male and female hormones.

I described the operative technique in 1930 pointing out that the ligature must not be placed level with the superior pole of the testicle but as near as possible

to the head of the epididymis, so as to avoid putting the albuginea of the testicle under tension and thus hindering the passage of the hormone of the genital glands into the blood stream. Briefly the technique is as follows:

(1) Place a silk ligature in the groove between the epididymis and the testicle, not level with the testicle but level with and even, if necessary, encroaching on the head of the epididymis. If the ligature be placed at the level of the testicle, as recommended by M. Chevassu and as is possibly the practice of other operators, the inelastic covering of the testicle is put under permanent tension whereby the internal secretion is likely to be obstructed, for the testicular hormone would no longer be able to pass through the fine pores of the albuginea and reach the veins which surround the testicle. If both means of egress for the testicular hormone—the vasa deferentia and the blood stream—are closed,

an extreme hypertension is produced by stasis and even the massive necrosis described by Slotopolsky may occur. The testicle becomes swollen and acutely tender, a complication which has been wrongly imputed to Steinach's ligature II. instead of to a faulty technique.

(2) Tie all the efferent ducts of the testicle (15 according to Kaufmann), applying the ligatures tightly but without dividing them. If the ducts are divided the external secretion would persist—which is not desired.

From 1927 up to the present I have relieved, by this very simple procedure, nearly 400 patients suffering from enlargement of the prostate. The operation can be done painlessly under a local anaesthetic, a fact that is alone sufficient to warrant for this simple procedure a wide appreciation.

RESULTS OBTAINED FROM STEINACH LIGATURE II

The general rejuvenating effect has been sufficiently observed, both in animals and man, by so many prominent men of science as to remove any doubt about it. As a frequent result of the ligature the heart is invigorated, the pulse becomes regular, the circulation improved, the arterial tension reduced to normal, headache and vertigo disappear, the appetite is improved, metabolism increased, calcareous deposits in arteries and joints are absorbed, musculature strengthened, the gait made firm and upright, sleep restored by the removal of nocturnal frequency of micturition, and clearness of thought and ability to undertake intellectual work restored. The effect of the ligature on the prostate itself is rapid in its action on spasm of the sphincter. It is less rapid in its action on the enlargement.

The painful straining gradually abates, the patient once more empties the bladder without effort, the

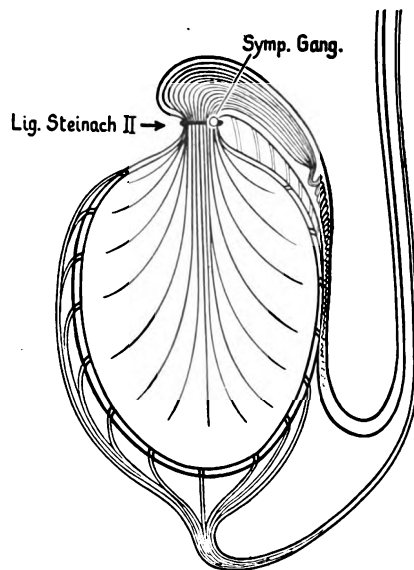

Diagram to illustrate the operative technique of Steinach's ligature II.

stream becomes more forcible, and in the majority of cases the residual urine entirely disappears. This result lasts for years and has been checked by a great number of cases in which there was no departure, either clinical or histological, of the prostate from the normal.⁵

Three of my cases will suffice to show the action of Steinach's ligature II., both on the sphincter spasm and on the hypertrophy.

1. *Spasmodic contraction of the bladder sphincter.*—Man aged 61; dysuria since the end of September and unable to pass more than 60 c.cm. urine at a time without great difficulty. Bladder distended up to the umbilicus. Ligature Steinach II. Oct. 13th, 1933. One and a half hours after the operation the patient voided 400 c.cm. urine and since then on an average 300 c.cm. four times a day. This patient had never had a catheter passed as he had a narrow and much inflamed phimosi.

2. *Hypertrophy of the prostate.*—In 1929 I performed a Steinach's ligature II. operation on a colleague aged 57, suffering from adenoma of the prostate, who was only able with great difficulty to pass a few drops of urine at a time. In order to estimate the improvement which followed, this patient measured the projection of his stream on the ground. This gradually increased from zero up to a metre which equals that of a young man. The improvement is still maintained after 6½ years.

3. A contractor, aged 64, who had suffered from difficulty of micturition for six months and had twice required catheterisation for retention. There was great hypertrophy of the prostate. Steinach's ligature II.

* The normal length of the prostatic urethra is 13 mm., but in hypertrophy it may attain 5 cm. or more. Heitz-Boyer noted after Steinach ligature II. a decrease in the size of the prostate and a shortening of the urethra, elongated by hypertrophy.

operation was performed on Jan. 9th, 1928. No indwelling catheter was necessary. The urine was passed more easily each day and after the twenty-third day the bladder was completely emptied. Since then he only passes urine once at night and has had no mishap or dysuria. The prostate is only slightly enlarged. He has now been under observation for eight years.

Conclusions

In the last few years I have done a very large number of ligature operations. They are painless and nearly all my patients have assured me that they have felt no discomfort either during or after operation. In cases without infection the length of treatment is 12 days and the mortality has been nil.

Since the operation entails no risk, the doctor can advise this treatment at the onset of prostatic trouble before there is any indication for prostatectomy. He may also advise it as a prophylactic against the changes in the interaction of the endocrines due to age and thus avoid hypertrophy of the prostate, a condition which untreated is always progressive. For the prophylaxis and treatment of senile changes in the prostate in the future the resources of endocrinology will be more and more utilised and in serious cases the patient will no longer have to choose between the use of the catheter and prostatectomy, to which operation the famous urologist Legue once referred as "a procedure which may prove fatal, but which will cure those it does not kill." Steinach's ligature II. can relieve a great many of the sufferers from prostatic enlargement however advanced their age without shock, pain, loss of blood, or risk.

CLINICAL AND LABORATORY NOTES

EFFECT OF THE HIGH-FREQUENCY FIELD ON SOME PHYSIOLOGICAL PREPARATIONS

BY SIR LEONARD HILL, M.B. Lond., LL.D., F.R.S.

SUPERVISOR, ST. JOHN CLINIC AND INSTITUTE OF PHYSICAL MEDICINE; AND

H. J. TAYLOR, B.Sc., Ph.D. Lond.

PHYSICIST, ST. JOHN CLINIC AND INSTITUTE OF PHYSICAL MEDICINE

SINCE so-called ultra-short waves are being used extensively for medical treatment an explanation of their mode of action is required. Various authors have claimed that effects can be produced in the ultra high-frequency electric field which are not explicable on the basis of rise in temperature. A good review of the literature is given by Mortimer and Osborne.¹ One of the more important papers is by Haase and Schliephake,² who claim that a selective lethal action on various organisms is a specific action of ultra-short waves. This is denied by Hasché and Leunig.³ Many of the claims made for the specific action of ultra-short waves rest on the early work of Schereschewsky,^{4 5} who studied the effect of the ultra high-frequency field on mouse and fowl sarcoma and carcinoma. More recently Schereschewsky has published⁶ a review which includes his earlier work and says that no case can be made out for ascribing effects as not being directly due to heat. Reiter⁷ has, however, claimed that high-frequency currents of frequency 8.82×10^7 sec.⁻¹ corresponding to a wave-length of 3.4 m. destroy rat tumours by a specific effect distinguishable from that of heat. The method of cooling the animal employed by Reiter is open to criticism, and Taylor⁸ has shown that if a more efficient method of cooling

be employed no destruction of the tumour and surrounding tissues results, when these are exposed in the high-frequency field. Moreover, he found that a low intensity without cooling of the treated parts is as effective as a high intensity with which artificial cooling is employed; further, a frequency corresponding to 4.5 m. wave-length is just as effective as that corresponding to 3.4 m.

EXPERIMENTAL WORK

As an additional proof of the fact that the action of the 3.4 metre wave-length is due to heat we have exposed the excised frog heart in the high-frequency field, the heart being immersed in a small quartz vessel containing Ringer's solution. The temperature of this solution was taken at times with a thermometer, the vessel of course being removed from the field for the purpose. Strict accuracy is not claimed for this method, but as the heat loss from the quartz vessel and contents is slow no great error is introduced. It was found that the heart continued to beat normally until a temperature above 30° C. was reached. The heart then ceased to beat but might be restored by cooling until a temperature above 35° C. was reached, when the heart failed to recover. As the behaviour of the frog's heart was exactly as it is known to be when merely submitted to increasing temperature in a bath of Ringer's solution, we conclude that the result of exposure to the high-frequency field is wholly due to heat. In case it were argued the high-frequency field acted rather on the saline solution than on the heart, a preparation was made of the thorax of a large frog containing the heart in situ, and this was suspended by cotton threads in the field with the lower part of the thorax uppermost. The heart was covered by the liver and the temperature was taken by removing the preparation from the

field and inserting the thermometer between the liver and heart. Here again the heart ceased to beat when the temperature rose above 30° C. and could be restored by cooling until the temperature reached 35° C. A preparation was then made of the head of the frog after the removal of the lower jaw and tongue, so that the ciliated epithelium covering the roof of the mouth was exposed. The activity of the cilia was tested by placing some granules of iron dust upon it and timing the progress of them towards the opening of the gullet. This preparation, placed in Ringer's solution in the quartz vessel, was exposed in the field and taken out at intervals and tested for temperature and for movement of the cilia. The cilia continued to show activity up to a temperature of 42° C., stopped at a higher temperature, but started again on cooling if they had not been heated to a temperature higher than 45°; above this temperature they stopped for good. Similar results were obtained when the whole head was suspended in the field on a thread, the temperature was taken by inserting the thermometer in the mouth, when the field was switched off; the activity of the cilia was observed after opening the mouth. This result also agrees with the known effect of temperature on the ciliated epithelium of the frog. Next a nerve-muscle preparation was exposed in the field in a quartz vessel in the same way. This was taken out for testing at intervals. The muscle continued to contract vigorously on faradic stimulation of the nerve up to a temperature of about 42° C. undergoing heat rigor at 45° C.

CONCLUSION

The behaviour of frog heart, cilia, and nerve-muscle preparation exposed in the high-frequency field corresponding to 3.4 m. wave-length is shown to be exactly the same as when merely heated in Ringer's solution; the biological effect of the field is thus due to heat.

This research was carried out with the aid of a grant, for expenses, from the Medical Research Council.

POLYCYSTIC DISEASE OF THE KIDNEYS

By W. E. COOKE, M.D. Liverp.,

F.R.C.P. Lond., D.P.H.

DIRECTOR OF THE PATHOLOGICAL DEPARTMENT, ROYAL INFIRMARY, WIGAN

THE case to be described has many unusual features.

History.—A. B., then 16 years old, was seen by her medical attendant in November, 1933. She complained of backache, lassitude, and dyspnoea on exertion. There was a considerable degree of anæmia. The urine contained large quantities of blood and pus, and bacteriologically *Bacillus coli* and *Staphylococcus albus*. There was no radiographic evidence of calculus, and the renal shadows were reported to be normal in size and shape, but after an injection of Uroselectan on Feb. 13th, 1934, none of the dye appeared in the renal areas at any time. She had appeared a healthy though under-developed girl until the onset of the symptoms. In October, 1933, she had had a very scanty menstrual period which lasted seven days, and was accompanied by a great deal of pain. This was the only period she had.

From November, 1933, to June, 1935, her condition fluctuated. The anæmia improved and for long periods the urine did not contain blood. She was able to take walks and carry on an apparently normal life.

Final illness.—On admission to hospital on June 23rd, 1935, at the age of 18, she was 4 ft. 7 in. in height and juvenile in appearance, with lack of development of secondary sexual characteristics. The blood pressure was 116/70 mm. Hg. The daily output of urine was 20–40 oz. until July 14th, the day before her death, when it was 2 oz. The specific gravity varied between 1004 and 1014, and the urine contained blood and pus. The blood-urea, ten days before death, was 700 mg. per 100 c.c.m., the serum calcium 6.7 mg., and the creatinine 3.4 mg. There was a progressive anæmia, the hæmoglobin falling to 30 per cent., with red cells 2,400,000 per c.c.m., colour-index 0.6, and the reticulocytes less than 0.1 per cent. The average diameter of the red cells was 7.3 μ . Total leucocytes were 16,000 per c.c.m. with a differential count of polymorphs 78 per cent., monocytes 4 per cent., and lymphocytes 18 per cent. The polynuclear count was: (I.) 6, (II.) 20, (III.) 40, (IV.) 22, (V.) 12. Bleeding from the gums was noticed about that time and a pericardial rub two days before death. The disease was apyrexial throughout.

POST-MORTEM FINDINGS

There was a fibrinous pericarditis with 2 oz. of serous fluid in the pericardium. The heart weighed 8½ oz. The liver, spleen, and pancreas were normal. The uterus was small and the ovaries unscarred. The bladder and ureters were normal, the pelvis dilated.

Kidneys.—Both kidneys were cystic. Each was 6 in. long, 3 in. wide, and 3 in. thick at the deepest part, and each weighed 15½ oz. The hilum notch was accentuated. The right kidney was translucent, the cysts being filled with a pale straw-coloured urine of specific gravity 1004, containing 0.5 per cent. of urea and a trace of albumin with a few pus cells. Many of the cysts of the left kidney were distended with blood-clot, some contained thick necrotic material and the remainder pale urine as in the right (Fig. 1). No tubercle bacilli were present and cultures gave *B. coli* and *Staph. albus*.

The adrenals were flattened and the normal contour lost. They were situated postero-internally immediately above the hilar notch, the external border becoming, with the altered position, anterior, the anterior surface postero-internal, and the posterior, antero-external. A considerable proportion of the kidneys was above their upper borders. They appeared, microscopically, normal.

Histology.—The small triangular areas at the junctions of the cysts presented the usual appearance of dilated ducts lined by cuboidal epithelium (Fig. 2). In the larger cysts this had become flattened. In the left kidney the renal tissue in these positions showed cloudy swelling of the tubular epithelium, tubules of unequal sizes, thickening of Bowman's capsule, and areas of round-celled infiltration (Fig. 3).

DISCUSSION

In addition to the abnormal situation of the adrenals, the unusual features of the case are:—

1. *Age.*—Oppenheimer¹ recording 59 cases of polycystic kidney gave the following ages when the condition was diagnosed:—

Years.	Patients.	Years.	Patients.
1–9	0	40–49	17
10–19	0	50–59	18
20–29	2	60–69	8
30–39	14		

Küster's² figures for 239 cases were:—

Patients.	Patients.
Stillborn or dying shortly after birth	30–40 years
.. 59	.. 24
Died in first year	40–50 "
.. 10	.. 53
1–5 years	50–60 "
.. 6	.. 41
5–10 "	60–70 "
.. 1	.. 10
10–20 "	70–80 "
.. 4	.. 6
20–30 "	80–90 "
.. 22	.. 3

Oppenheimer collected from the literature 29 cases between the ages two and twenty years and suggests that these represent the connecting link between the new-born and the adult types of the same disease. Until we know more about the ætiology his contention

cannot be confirmed nor refuted, but his own and Küster's figures are remarkable in emphasising the rarity of the condition between the ages of one and twenty and the greatest incidence in the 30-60 age-group.

2. *Infantilism.*—The terms renal dwarfism, renal infantilism, and renal rickets have been used synonymously, but as Ellis and Evans³ point out, many cases fall clearly into one of these groups and should be differentiated. The present case would be placed into the group of renal infantilism. The rarity, in fact total absence, of dwarfism, rickets, and infantilism recorded in connexion with polycystic kidneys in contrast with their frequency in cases of contracted kidney and hydronephrosis and dilatation of the ureters occurring before puberty may be explained by the fact that serious diminution in the amount of effective renal tissue in the former disease does not usually take place until after twenty years of age. Although it is difficult to believe on viewing cystic kidneys, the two-thirds of renal substance necessary to life (reduced now by some workers to

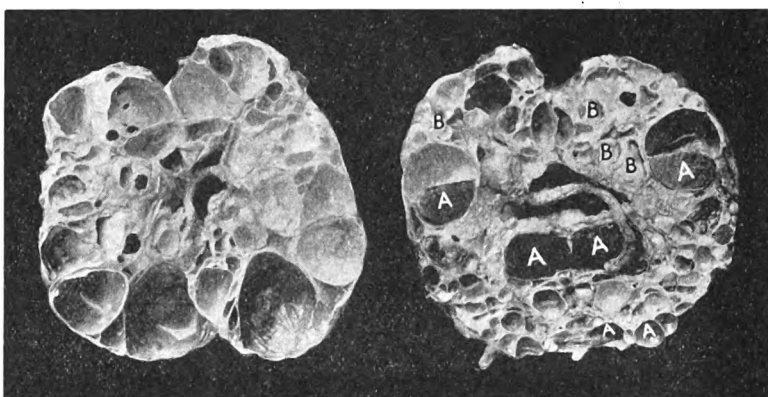

FIG. 1.—Photograph of the polycystic kidneys, sectioned, described in text. The right kidney was transparent, the cyst containing a pale yellow urine. The left shows some of the cysts filled with blood-clot at A, others filled with necrotic material at B. The cysts that appear empty in the photograph contained pale yellow urine. The ureters are seen in the centre of each kidney. (× 1.)

relationship between anæmia and renal insufficiency. They attribute the anæmia to a disturbance in hæmopoiesis. This is also suggested by the blood in the present case. Two factors may have been jointly responsible for the progressive anæmia—renal insufficiency and infection of the kidneys.

But the polynuclear count points to some radical dysfunction either in the production or elimination, or alteration in the life-history of the polymorphs. The right-handed polynuclear count—(I.) 6, (II.) 20, (III.) 40, (IV.) 22, (V.) 12—giving a weighted mean of 3.14 is remarkable in itself in a case with a gross infection, still more so with a leucocytosis of 16,000 per c.mm., and is in my experience unique. The polymorphs generally were of normal size, but macro-polycytes were not infrequently seen (Fig. 4). The lobes of the nuclei were so

FIG. 2.—Photomicrograph of tissue between cysts, showing dilated tubules lined with cuboidal epithelium. The epithelium lining the larger cysts on each side of the triangular piece of tissue is flattened. (× 75.)

Photomicrographs by C. F. Hill and W. E. Cooke.

FIG. 3.—Photomicrograph of renal tissue from left kidney, showing thickened Bowman's capsule, variation in size of the tubules, and at × an area of round-celled infiltration. (× 75.)

one-sixth) must have functioned over the period of puberty.

3. *Blood analysis.*—The blood-urea, 700 mg. per 100 c.cm., was the highest I have seen. The serum calcium fell from 10.8 to 6.7 mg. a few days before death. The amount of creatinine was unusually high.

4. *Blood count.*—Brown and Roth⁴ stressed the

numerous and the fragments so contorted and superimposed as to make the count the most difficult I have encountered. Figs. 5, 6, and 7 were taken from almost successive fields in a blood film and will afford some idea of the task.

Similar counts are recorded in pernicious anæmia,⁵ but in that disease the polymorphs tend to be larger

FIG. 4.—A macropolycyte of type 1 illustrating large size of cell and hypersegmentation of the nucleus. (× 1000.)
FIGS. 5 to 7.—Three almost successive fields in a blood film illustrating polymorphs with hypersegmented nuclei, and the difficulties encountered in making a polynuclear count. (× 1000.)

and the basichromatin in the nucleus less in amount and therefore less densely staining than in the present case, so that the contortions and divisions are more easily followed.

SUMMARY

(1) The case is one of polycystic kidney associated with infantilism. (2) Although gross infection of the renal cysts was present, the case was apyrexial throughout. (3) The blood-urea reached the high figure of 700 mg. per 100 c.cm. of blood. (4) The

polynuclear count was right-handed. (5) The anatomical position of the adrenals was abnormal.

MEDICAL SOCIETIES

ASSOCIATION OF CLINICAL PATHOLOGISTS

THE ninth annual meeting of this association was held, by the courtesy of Sir Henry Wellcome, at the Wellcome Physiological Research Laboratories, London, on Jan. 25th. Dr. J. G. GREENFIELD occupied the chair.

Dr. I. MUENDE (London) spoke on the

Clinical Pathology of Skin Diseases

with particular referencé to parasitic and fungal infections. He pointed out that in acarus infection of human type the rash might be widespread and the manifestations varied but that the characteristic burrows would be found between the webs of the fingers, on the glans penis, in the axillary folds, and in women under the breasts. The parasite could be demonstrated by shaving off the skin at the end of the burrow and examining under the microscope. In infection derived from pet animals type burrows might be missing; the eruption was usually confined to the hands and arms and would disappear on removal of the infecting pet. In fungal infections the speaker laid stress on the identification of the type, which was best done by culture; in those acquired from cat, dog, or canary, removal of the source of infection was essential. Kerion was usually due to animal infection. The black dot type of ringworm was becoming much more common; in this type the extraction of hairs for examination presented difficulties which were best met by the use of a comedo extractor. Achlorion infection might be acquired from mice, in which animals it produced a fatal encephalitis. Dr. Muende recorded one case which had been associated with an epidemic among mice in the place of work. Moniliasis was a not infrequent cause of paronychia; the fungus could be identified by scrapings taken from under the nail bed even in the absence of pus; it was particularly prone to occur in barmaids, bakers, and pastry cooks. Dyshidrosis was due to sensitisation to a fungus infection usually by an epidermophyton between the toes. A useful guide to the presence of such sensitisation was the reaction produced by the intradermal injection of the soluble products from a culture of mixed fungus of the same type. Eczema might be due to sensitisation to vast numbers of "eczematogens"; Dr. Muende described the "patch test" for the identification of such sensitisation.

Dr. C. M. WENYON, F.R.S. (London), spoke on the clinical pathology of

Protozoal Infections

He said that, though amœbic dysentery was probably not so common in this country now as in the years immediately succeeding the war, numerous carriers of pathogenic amœbæ still existed. Many of

these carriers were not aware that they had ever had amœbic dysentery and many of them experienced very little inconvenience. Amœbæ might be found in vast numbers in the stools of those with very little in the way of symptoms and this had led some people to conclude that there were two types of histolytic amœba, one type (called "dispar") being of relatively low pathogenicity. Dr. Wenyon discussed the difficulties in the identification of amœbic infection and emphasised the necessity of examining fresh specimens of feces; repeated examination might be necessary and protozoa were rarely found in very liquid feces. Amœbæ might be found in scrapings taken from ulcers through a sigmoidoscope when they could not be found in the feces. All intestinal parasites except giardia could be cultivated, but this method was only possible in institutions dealing with very large numbers of cases. Giardia was an inhabitant of the duodenum and could be obtained by means of duodenal intubation; cholecystitis had been ascribed to it but Dr. Wenyon did not regard the case as proven. In the diagnosis of protozoal blood infections a good stain was the first requisite. Except in the case of kala-azar culture was of no use as a diagnostic measure. In the diagnosis of bilharzia and schistosoma infestation a useful aid was the intradermal injection of the appropriate antigen.

Dr. G. W. GOODHART (London) pointed out that, while diagnosis of trichomonas infection of the vagina could be made from fresh secretion, the parasites could not be demonstrated in dried films.

Dr. R. V. FACEY (Bournemouth) stated that he came across large numbers of cases of vaginal trichomoniasis and that these responded readily to treatment with arsenical pessaries.

Dr. H. P. HIMSWORTH (London) spoke on the

Significance of Blood-sugar Levels in Diabetics

He asked why the blood-sugar rises in diabetes? The classical explanation is failure in carbohydrate storage. He however suggested that the rise of the blood-sugar was a compensatory phenomenon. He showed graphs indicating the course of the blood-sugar and of the ketosis in a severe case of diabetic coma; when sugar was given in large amount without insulin the blood-sugar rose but the ketosis became less; he cited an instance of diabetic coma in which the blood-sugar had been forced up by the administration of glucose to over 1000 mg. per cent. with decrease in ketosis and corresponding improvement in the clinical condition. On giving sugar to the diabetic more sugar was excreted than was taken; similarly the establishment of diuresis, though it had no effect on the blood-sugar level, would result in increased excretion of sugar. He suggested that the main factor in diabetes was an incapacity to utilise carbohydrate until the blood-sugar had risen to a

certain level above the normal; on this account it was harmful to withhold sugar from the diabetic. The level of the blood-sugar bore no relation to the clinical condition.

Dr. S. C. DYKE (Wolverhampton) expressed his agreement with Dr. Himsforth that more harm was done by withholding than by giving excess of sugar to the patient in diabetic coma, but pointed out that a high blood-sugar encouraged diuresis and therefore favoured the further dehydration of the patient; dehydration was the main danger in coma and reduction of the blood-sugar was a necessary step in combating it. In the established diabetic he asked whether continued hyperglycemia might not be one of the causes of the vascular degeneration which is the main cause of morbidity.

Dr. J. A. BOYCOTT (London) described the

Diagnosis of Teratoma Testis

by means of the Aschheim-Zondek reaction. The method depended upon the fact that sufferers from malignant tumours of testis excrete in the urine excessive amounts of gonadotropic hormone; this was not the case with simple and inflammatory tumours. Two sets of mice were used; one series received graduated injections of concentrated and the other of unconcentrated urine. By means of a table it was possible to calculate the amount of gonadotropic hormone excreted. The test was useful not only in diagnosis but also in controlling the results of operation and radiotherapy.

Dr. DYKE also described a case of accidental transmission of malarial infection in the course of blood transfusion; the donor had lived in India but had never known that he had had malaria.

In the course of the afternoon Dr. S. H. Daukes, curator of the Wellcome Museum of Medical Science, conducted members round the magnificent medical museum of the institution.

GLASGOW OBSTETRICAL SOCIETY

At a meeting of this society on Jan. 22nd Dr. JOHN GARDNER, the president, took the chair, and Dr. DUGALD BAIRD read the paper published on p. 295 under the title of

Maternal Mortality in Hospital

In the subsequent discussion Dr. J. DUNLOP said he did not accept the nasopharyngeal origin of puerperal sepsis, and attributed his own improved results in general practice to the use of gloves. He thought many errors in judgment resulted from overtiredness, after a long day in practice. He agreed that spacing of births was most desirable, and put in a plea for birth control clinics run by the local authority.

Dr. JAMES COOK thought that uterine inertia was often due to over-indulgence in strong tea. He was alarmed at the increased number of Cæsarean sections and asked why induction was not performed more often. He was in favour of a great extension of antenatal care, and advocated medical examination before marriage.

Dr. A. S. M. MACGREGOR (M.O.H. for Glasgow) was not convinced that there was an increase in the maternal mortality for Scotland, the apparent rise being due to more accurate certification and statistical fallacies. There seemed no doubt that technical practice was improving. He thought that an analysis such as Dr. Baird's, where each case was assessed individually, was the best method of

studying the problem. The incidence of sepsis in Scotland had not diminished in the last few years, especially that of sepsis due to the hæmolytic streptococcus, and he believed that this might be explained by the increased virulence of the hæmolytic streptococcus in northern latitudes. He thought the non-coöperation of patients themselves was an important factor in maternal mortality. He asked if Dr. Baird would put greatest emphasis on the provision of antenatal beds in a government policy.

Dr. DOUGLAS MILLER advocated Cæsarean section in those cases of uterine inertia with stigmata of endocrine deficiency. He said they had been disappointed with the results of the use of masks in Edinburgh, and asked if some of the improvement in Glasgow was not due to more careful segregation of "suspect" cases.

Prof. SHAW DUNN remarked that antenatal care had not altered the incidence of albuminuria, since this condition probably depended on intimate physiological and dietetic causes, occurring early in pregnancy.

Prof. JAMES HENDRY thought that much of the improvement in results at the Royal Maternity Hospital was due to the reorganisation of the staff which allowed continuous service and team-work, and to better coöperation with the general practitioner and local authority. The extended use of Cæsarean section in the treatment of placenta prævia was a great advance.

Dr. BAIRD replied that he did not attribute the fall in the sepsis-rate to better segregation. The most striking fall occurred in sepsis following spontaneous delivery, which, as Colebrook had shown, was almost always due to the hæmolytic streptococcus, in contrast to sepsis following abnormal labour, where the hæmolytic streptococcus was the causal organism in only 30 per cent. There was little evidence of infection being transferred from one patient to the other, for the cases of sepsis were sporadic and infection seemed to take place at the time of labour. He was convinced of the nasopharyngeal source of infection by the hæmolytic streptococcus. He certainly thought that more antenatal beds should be an important feature of a government plan; but great tact was often necessary to persuade the patient to stay in hospital.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

At the annual meeting of this society, held in Manchester on Jan. 24th, with Dr. RUTH NICHOLSON, the president, in the chair, a paper on

Extroversion of the Ovaries for Secondary Functional Amenorrhœa

was read by Dr. K. V. BAILEY. Recent advances in endocrine therapy, he said, had done much to simplify the treatment of many uterine disorders, and Kaufmann's work had undoubtedly established a rational treatment for functional amenorrhœa. But even the large doses of hormones used by Kaufmann gave irregular results and Dr. Bailey thought it desirable to bring forward an operative treatment he had adopted in 16 cases during the past five years, especially as its results indicated a probable cause for the relative failure of endocrine therapy in some cases of secondary amenorrhœa. In this condition uterine junction had once been present, and the true failure was probably in ovary or

pituitary. As a rule, the patient was otherwise healthy and well developed, showing no sign of gross endocrine imbalance. In the ovaries themselves lack of follicular ripening and ovulation might lead to multicystic disease or to chronic cirrhosis of the tunica with progressive fibrosis of the ovarian stroma—findings most readily attributable to a basic pituitary deficiency. Once established, these changes were permanent; although ovulation might occasionally be induced in an ovary showing advanced multicystic disease, it could only occur in a small area which still functioned and found an outlet to the surface. Regeneration was as impossible as in a multicystic kidney. The operation he had adopted was based on these facts and sought to assist maturation and ovulation in the remaining follicles by facilitating their approach to the surface. It might seem to break the rules of surgery, because a raw surface was deliberately produced in the pelvic cavity, but this raw surface faced downwards towards the pouch of Douglas and was not in contact with any peritoneal surface. What he did was to excise a wedge of tissue sagittally from the cystic or cirrhotic ovary, with its apex at the hilum; then by means of sutures the organ was turned almost inside out—or, more accurately, the cut halves were flattened outwards. In no case had Dr. Bailey seen post-operative adhesions or symptoms attributable to them, and he now looked on the operation—which he usually preceded by dilatation and curettage—as thoroughly safe. Endocrine treatment had been given in addition, including Antuitrin S, but judging by control cases the doses were too small to have any effect per se, though they might stimulate follicular growth, to the stage of ovulation, in the extroverted ovary. Of the 16 cases treated, the duration of the amenorrhœa had been over six months in 4, over a year in 4, and over two years in 3; there were also 5 cases with a constant periodicity of two to six months. Regular menstruation had been established and continued in 12 of the 16 cases, the operations being performed in 1932 (1 case), 1933 (1), 1934 (4), and 1935 (6). Of the 4 other patients, 1 had begun to menstruate three years after operation, 2 had had single periods, and 1 had not yet menstruated at all; in these 4 cases the initial amenorrhœa had lasted, respectively, one year, seven months, six months, and two years. In 2 of the successful cases other treatment (including curettage and administration of antuitrin S or œstrin or both) had been given for three months before operation without effect. On one occasion, Dr. Bailey said, he had seen at laparotomy an ovary which had been resected and repaired a few months previously. Surface healing had taken place by the formation of a thin red and wide scar—much more delicate at that stage than the tunica albuginea itself—and it was probable that a similar scar formed on the cut surface of the extroverted ovary, which would easily allow of ovulation. Though adequate hormone therapy should always be attempted where possible, and might be successful where amenorrhœa had not been too prolonged, he believed that the operation described might be helpful in cases which proved otherwise resistant.

Mr. J. E. STACEY said that the late Mr. King had performed a similar operation on a number of cases of dysmenorrhœa in the presence of cystic ovaries. He was inclined to think it would be more useful for that condition than for secondary amenorrhœa.—Prof. D. DOUGAL thought the operation very drastic if the patient was young and if the amenorrhœa was only of six months' standing. Periods of

amenorrhœa of this length were by no means uncommon in young unmarried women.—Mr. T. N. A. JEFFCOATE said there were really three types of amenorrhœa: (1) where the ovary was not functioning as an endocrine organ; (2) where there was persistence of the œstrin phase; and (3) where there was persistence of the lutein phase. A differential diagnosis could be obtained by the examination of curettings, and the condition might be relieved in a number of ways—e.g., by injections of anterior pituitary hormone, by mental shock, or perhaps as a result of the shock of an operation.—Dr. D. C. RACKER considered that a persistently low blood œstrin was sometimes a factor in the production of amenorrhœa of this type.—Dr. BAILEY, in reply, agreed that operative treatment was certainly drastic but felt that it had a definite place where other methods had failed.

Granulosa-cell Tumour

Prof. DOUGAL said that during the last ten years there had been a revival of interest in certain ovarian tumours which had a hormonal influence on the sexual characters of the host. These tumours were derived from undifferentiated cells in the ovarian mesenchyme which though not utilised during embryonic development still retained their powers of growth and later in life were able to proliferate and form new growths. If the sexual influence of these cells was towards masculinity the tumour was known as an arrhenoblastoma; if towards femininity, as a granulosa-cell tumour; and if neutral, as a dysgerminoma. He described the case of a married woman of 41 who complained of excessive and too frequent menstrual loss, and who had a large solid abdominal tumour indistinguishable clinically from a uterine fibroid. At operation the tumour was found to be ovarian and was removed, the uterus and the other ovary being left behind. Microscopically it proved to be a very large granulosa-cell tumour composed of large numbers of alveoli containing round cells with deeply stained nuclei. Commenting on this case Prof. Dougal pointed out that granulosa-cell tumours are usually unilateral and have a very low degree of malignancy, if they are not actually benign. They may develop at any period of life and their biological influence is due to excessive secretion of œstrin. Therefore, if the tumours develop before puberty sexual precocity is the result; if during the reproductive period, excessive and too frequent menstrual loss; and if after the menopause, post-menopausal hæmorrhage.

The discussion which followed centred round the distinction between the granulosa-cell tumour and the Brenner tumour, which is derived from Wolffian relics in the hilum of the ovary. Mr. JEFFCOATE held that their distinction on histological grounds must be very fine and that a physiological basis would be more satisfactory—i.e., if a tumour produced œstrin, and consequently a disturbance of the menstrual cycle, it was a granulosa-cell tumour, while if it did not it must be a Brenner tumour.—Prof. DOUGAL said he was inclined to agree.

Dr. J. W. BRIDE described three cases of hydro-peritoneum secondary to ovarian tumours, and showed a specimen of malignant Fallopian tubes.

Corrigendum.—Mr. A. W. Cubitt points out that the remarks attributed to him on p. 260 of our last issue were made by a subsequent speaker.

REVIEWS AND NOTICES OF BOOKS

Outlines of General Psychopathology

By WM. MALAMUD, M.D., Professor of Psychiatry, State University of Iowa. London: Chapman and Hall. 1935. Pp. 462. 21s.

A SYSTEMATIC account of psychopathology, such as is here supplied, is greatly needed by the beginner in psychiatry. Presentations of the theory of this or that school abound, but for an ordered arrangement of the known data and the less debatable explanations for their occurrence the reader has had to turn to the translation of Kretschmer's text-book of medical psychology, itself disproportionate in so far as it reflects the personal investigations and interests of its author. Prof. Malamud's book is well balanced and non-controversial. Through having worked in Heidelberg he is familiar not only with the holistic method of von Weizsäcker's earlier phase but also with the phenomenology of Jaspers, to whose more detailed and formal treatise he is clearly indebted. Chief, however, among those whom he mentions as his guides, one sees Adolph Meyer whose salutary refusal to guess overmuch is a sure guard against the common faults of psychopathologists.

The book begins with a plain definition of psychopathology and discussion of its relationships and limitations, the fields in which it may be applied and the material upon which it draws. The next part describes and analyses the phenomena under the general heads: behaviour and experience. The various determinants in pathogenesis are next examined in turn, the structure of personality is discussed, and the synthesis of abnormal functions in the various types of morbid reaction is illustrated, in the last part of the book, by clinical material. In spite of its length the work is properly named: it is only a framework or outline, in which the experienced psychiatrist must not expect to find recondite problems or much detail. The difficulties of the author's task have been so well overcome that it would be unjust to reproach him for omissions that are judicious and doubtless intentional.

Immunology

By NOBLE PIERCE SHERWOOD, Ph.D., M.D., Professor of Bacteriology, University of Kansas, and Pathologist to the Lawrence Memorial Hospital, Lawrence, Kansas. London: Henry Kimpton. 1935. Pp. 608. 25s.

THIS is a laboriously and conscientiously produced volume which covers the main ground of immunological science. Such subjects as cellular immunity, serological tests, blood grouping, the chemistry of antigens, and hypersensitiveness are treated in detail and the analysis of a large body of immunological literature is made available. At times the "scissors and paste" method of compilation is unduly obtrusive, but some chapters, notably those on hypersensitiveness, are well done and the author clearly speaks from his own experience. Among the less satisfactory chapters are those on toxin and antitoxin. Here Prof. Sherwood seems to tread with a somewhat uncertain step, though the subject is a fundamental one in immunology. We were unable for example to find any clear description of the present unit of diphtheria antitoxin: the accounts given on pages 116 and 212 are inadequate not to say misleading. The sections on active immunisation against diphtheria also seem to have been compiled

somewhat uncritically. It is surprising to find the expressions "*C. diphtheria*" and "*Cl. botulinus*" repeated in several places in an otherwise carefully written book. To the instructed reader the book will prove of considerable value as it covers in well-expressed summaries a large amount of modern immunological literature, particularly that of American origin, and provides full references to original sources.

The Foot

By NORMAN C. LAKE, M.D., M.S., D.Sc. Lond., F.R.C.S. Eng., Senior Surgeon and Lecturer on Surgery, Charing Cross Hospital. London: Baillière, Tindall and Cox. 1935. Pp. 330. 12s. 6d.

DISORDERS of the feet, which are extremely common, have been treated lightly by the medical profession until recent years, to the profit and satisfaction of unorthodox practitioners and the vendors of patent remedies. Painful feet, to which doctors and nurses are especially prone, are liable to alter the whole outlook of the individual and make work a burden. It behoves us therefore to study their causation and treatment with minute care. This book is intended for the practitioner and general surgeon, perhaps for the masseur and chiropractist, and does not deal with elaborate orthopædic details, which can be studied elsewhere. Enough about the evolution, anatomy, and physiology of the foot is presented in readable form to make a foundation for the later chapters dealing with the aetiology and treatment of its common disorders. One chapter is devoted to foot-wear, and one to the mechanism of walking, in relation to the weakness of the modern foot. Needless to say, woman's footwear receives just criticism. The commoner operations recommended are briefly described in a separate chapter, and methods of anaesthesia are discussed. The old anatomical terminology is used throughout (except for one or two mistakes), but it would be to the advantage of future generations of students if the terminology of the Anatomical Society of Great Britain, now used in two or three text-books, could be adopted in future editions. It is difficult to understand why anatomists and surgeons should speak different languages. There are some printer's errors which should also receive attention in a future edition.

The book can be strongly recommended as an excellent exposition of disorders of the feet.

Experimental Physiology

By M. B. VISSCHER, Ph.D., M.D., Professor of Physiology in the University of Illinois, Chicago; and P. W. SMITH, Ph.D., Associate in Physiology in the University. London: Henry Kimpton. 1935. Pp. 191. 15s.

LIKE most practical physiology text-books this is based on a course of experiments made by the students of a particular medical school. Such courses have much in common, and the authors here are careful to make no claim for originality in their subject matter presented. In this they are modest, for we have not seen in other books simple instructions for the demonstration of experimental polyneuritis in the pigeon, or for the observation of the oestrous cycle and the gonadotropic (wrongly called oestrogenic) properties of pregnancy urine. Experiments are suggested for every "system" of the body, and the

frog muscle experiments are cut down to suitable proportions. The only criticism with regard to allocation of space is that the nervous system and the special senses are perhaps over-represented. The instructions are clear and concise, and no teacher will read through the book without picking up useful technical hints. An unusual feature is that the illustrations are nearly all photographs, a road to perfection which most authors have abandoned as being too full of pitfalls. In this case the experi-

ment is justified, the lay-out of the apparatus and the photography being excellent. The last chapter is an appendix on methods, preparations, apparatus, dosage of drugs in animal experiments, and so forth, and is of real value. Selected references to original papers and reviews are given throughout. The general impression left by the book is that of a well turned-out and practised piece of work with no loose ends, and the publishers as well as the authors deserve praise for its production.

NEW INVENTIONS

INSTRUMENTS FOR USE IN OPERATIONS UPON FRACTURES OF THE NECK OF THE FEMUR

THE following instruments have been designed for use in operating upon fractures of the neck of the femur by the lateral approach.

LLOYD-KING NAILS (Modified from Smith-Petersen)

These stainless steel nails are a modification of the Smith-Petersen triradiate nail and are designed for

use with Eric Lloyd's director, though they are equally suitable for any other method of operating upon fractured necks of the femur. The nails differ from the standard design in the following particulars: 1. The head is twice the usual thickness, being 1 cm. deep, and is traversed by a threaded hole 6 mm. in diameter. 2. The nails are made in seven lengths from 7 cm. to 10 cm. with an interval of 0.5 cm. between each consecutive pair. 3. The length of each nail (excluding the head) is engraved on the head and no engraving is permitted on any other part of the nail. 4. Each of the three flanges is snagged like the edge of a saw for 3 cm. adjacent to the head. This is intended to counteract any tendency for the nail to come out when it has once been inserted. 5. One of the three flanges is made 3 mm. shorter than the others. This shorter flange

Metal case for nails.

is directed proximally when used with Eric Lloyd's director. 6. The nails are made in two diameters—viz., the ordinary standard 13 mm. and a larger one of 16 mm.

STERILISABLE METAL CASE FOR LLOYD-KING NAILS

This is a strongly made metal cylindrical case with a screw-top lid. It contains a cruet stand

fitting, which is made to take one set of seven Lloyd-King nails of 13 or 16 mm. diameter. The case is half filled with water and the lid screwed down half a turn before boiling the nails. Thereafter, no handling is necessary, and as the length of each nail (excluding the head) is engraved on the outside of the head it is easy to find the desired length of nail. Moreover, the absence of any one of the seven sizes of nail is immediately noticed if they are kept in this case.

LLOYD-KING NAIL INTRODUCER

This is a threaded stainless steel rod which screws into the head of the nail. It is used to pick out the selected nail from the sterilised case containing the set of seven and to start the nail the first few millimetres into the cortex of the great trochanter. All temptation to handle the nail is thus removed, and

the short flange of the nail can be placed in the correct orientation during introduction. As soon as the nail has started on its course the introducer can be unscrewed and an ordinary punch used to complete the nailing.

LLOYD-KING NAIL EXTRACTOR

The removal of triradiate nails may be extremely difficult and some patterns of extractors necessitate full exposure of the whole head of the nail and even a portion of the shaft before the instruments can be engaged. This extractor screws into the head of the nail and considerably simplifies removal, inasmuch as exposure is minimised. It was described by Thomas King, and is here modified in three respects: 1. The engaging screw is much longer and of larger

diameter. 2. A single extractor will remove nails of either 13 or 16 mm. diameter. 3. A larger and more convenient screw handle has been supplied.

These instruments have all been made for me by Messrs. Down Bros., Ltd., St. Thomas's-street, London, S.E., but the director (described in THE LANCET, 1935, ii., 129) is made by the Medical Supply Association.

ERIC I. LLOYD, M.B. Camb., F.R.C.S. Eng.

THE LANCET

LONDON: SATURDAY, FEBRUARY 8, 1936

SAFETY *versus* COMFORT IN CHILDBIRTH

THE large majority of confinements are now attended by a midwife and it can hardly be long before every expectant mother will require the attendance of a woman whose experience and responsibilities are legally defined. In 40-50 per cent. of the cases she attends the midwife calls in a doctor, and in a proportion of confinements which varies from 10-70 per cent. in different parts of England a doctor has been previously retained by the expectant mother; but this leaves many women who cannot expect any alleviation of the pains of childbirth except what they can get at the hands of a midwife. Fifteen years ago the Home Secretary gave every midwife who has notified her intention to practise the right to carry in her bag Dover's powder and laudanum as well as chloral and bromide; with these the midwife working alone has been able to ensure rest and relaxation for the anxious and restless patient. The injunction of the Central Midwives Board that no drug should be used by a midwife unless she has been thoroughly trained in its use and is familiar with its administration seems to have been conscientiously followed. But none of these sedatives is effective in the second stage of labour, and four years ago Miss E. M. PYE suggested and Mr. L. C. RIVETT worked out the use of chloroform in the form of 20-minim capsules, to be crushed and administered by the midwife, or by the woman to herself, during brief periods of severe pain as they arise. Under the leadership of Mrs. STANLEY BALDWIN the proposal was taken up warmly by the National Birthday Trust Fund, which was then financing the provision of qualified anaesthetists in maternity wards, and at a festival dinner of the British College of Obstetricians and Gynaecologists Mr. BALDWIN said he wanted to see the day come when the best form of anaesthesia should be within the reach of every parturient woman. In reply, Dr. J. S. FAIRBAIRN, speaking as president of both Board and College, pleaded that he was ground between upper and lower millstones—between those who would trust the midwife with any available anaesthetic, and those who hesitated to place dangerous weapons in the hands of women not qualified to use them. What, he said, was needed was a scientific clinical test on a large scale, for the method adopted must be without increased risk for mother or child. This is in brief the origin of the investigation into the use of analgesics in midwifery, the report of which appeared last week and was summarised in our columns (pp. 282-3). The subcommittee of the College entrusted with the investigation consisted at first of Dr. FAIRBAIRN, Mr. EARDLEY HOLLAND,

Prof. FLETCHER SHAW, Mr. RIVETT, and Mr. CHRISTIE BROWN. Later Mr. G. F. GIBBERD was co-opted to assist in drawing up the forms of record, Dr. Z. MENNELL to advise about the analgesics employed, Prof. E. MELLANBY as nominee of the Medical Research Council, and Dr. MATTHEW YOUNG for expert statistical help. The investigation was a wide one; 36 hospitals in various parts of the British Isles took part in it, and they were kept in touch by supervisors prepared to clear up doubts as to the purpose of the investigation and to give instruction in the use of the standard methods. Although the special reference was to the use of chloroform capsules by midwives the investigation was widened to cover the efficacy and safety, in the hands of various groups of administrators, of nitrous oxide, of paraldehyde, and of chloroform given in three different ways.

On all these methods of producing analgesia the committee have come to definite conclusions, on which equally definite recommendations are based. The ground can at once be cleared of paraldehyde per rectum because "it does not provide adequate analgesia at the time of the actual birth." Gas and air administered by the Minnitt apparatus "is a safe and satisfactory method of producing analgesia, although the apparatus is expensive and the nitrous oxide costly"; its use should be "extended to the practice of midwives, provided they are specially trained in its administration." Chloroform, on the other hand, given by any method, "should not be used by midwives acting alone. This conclusion," the report says, "has been reached with regret, but both immediate and delayed dangers, which are well recognised, occurred in this investigation, and it is not possible fully to guard against such occurrences if the administration of chloroform is in inexperienced hands. This finding should not, however, be taken as prejudicing the use of chloroform by registered medical practitioners, who, aware of the dangers, can take precautions to lessen the risks." These recommendations it will be noted bear on the question of safety rather than on that of efficacy, for, to repeat Dr. FAIRBAIRN'S words, the method adopted must be without increased risk for mother or child; but it is interesting to note the high degree of efficacy both in gas-and-air and chloroform analgesia, no matter what the method or agent of administration. The proportion of patients who obtained satisfying relief from pain varied from 79 up to 94 per cent.; it was 84 per cent. for chloroform capsules administered by the midwife (in 695 reported cases). This method which was the primary object of the investigation is therefore well justified by the relief afforded, and it is natural to inquire more closely into the reason for the conclusion that it should not be used by midwives acting alone.

Among a total of 4975 cases in which chloroform was given by various methods to produce analgesia, with or without general anaesthesia, 6 mothers died; and these deaths were studied in detail. In 3 of the 6 the conclusion is reached that chloroform was in no way responsible for death;

in 2 it was an important factor in the fatal issue; and in 1 chloroform was directly responsible for death. This last case was the only one in which chloroform was given in the form of capsules. The patient was a primigravida, 21 years of age, with well compensated mitral disease, who had received a standard dose of paraldehyde and late in the second stage was given chloroform capsules by a medical student. When the head was about to be born the woman became difficult to control and six capsules were used within two minutes. This death, says the report, illustrates that chloroform capsules are not foolproof and shows that the display of precise instructions as to dosage is not a sufficient safeguard against misuse, even in hospital. It will be noted however that the report contains no evidence of harm being done by chloroform capsules to any woman in normal health, nor of any harm being done by chloroform capsules given by a midwife, or even by a pupil midwife. On the other side we have a statement to the Birthday Fund in 1933 that among 4000 patients who had capsules at Queen Charlotte's and Middlesex Hospitals there was no maternal death, while out of every 100 women 90 obtained some, and 50 very great, relief. Commenting on these figures Mr. RIVETT declared that "this is a completely safe and foolproof method of relieving the intense pains of childbirth and one which is easily learned at a very short course of instruction"; and if the committee have obtained evidence which reverses this verdict, they have not produced it. It was already common knowledge that some patients given chloroform capsules are noisy and difficult to control during the second stage, but so far as we are aware this has never led a midwife to disobey instructions and crush capsules so freely as to produce an over-concentration of chloroform vapour. In the other two fatal cases in which chloroform was blamed it had been given for prolonged periods by the Mennell inhaler and was later pushed to full surgical anaesthesia, the illness being typical of the diffuse acute necrosis of the liver which occasionally follows the administration of chloroform. For example, in his analysis of 999 fatal cases in a Glasgow maternity hospital (see p. 295 of this issue) Dr. DUGALD BAIRD finds that delayed chloroform poisoning was the sole cause of death in 5 forceps deliveries after long labour. The report admits that it was the full surgical anaesthesia rather than the preliminary analgesia which was the important factor in the cause of death, but regards the previous prolonged analgesia as weighting the balance against recovery. Whatever lesson is to be drawn from these cases against the use of deep chloroform anaesthesia in obstetric operations when so safe an anaesthetic as nitrous oxide is available, they seem again to have little if any bearing on the safety of a limited number of chloroform capsules, spaced at intervals of not less than five minutes, in the hands of a midwife acting alone.

But while the report is clear that chloroform by any method should not be used by midwives acting alone, it recognises that the administration of gas and air is a safe and satisfactory means of

producing analgesia, and recommends its extension to the practice of midwives under proper controls. Unfortunately, as we have seen, the committee find themselves obliged to lay stress on the expense of the apparatus and the costliness of the nitrous oxide. The expense of the apparatus is not arguable, but the cost of the gas in the investigation was enhanced by wastage "owing" it is said, "to the fact that, as the apparatus is now constructed, leakage may occur at many places unless constant attention is given to minor adjustments." It seems that in the investigation itself the leakage in question assumed such proportions as to invalidate any estimate of the cost of gas-and-air administration per patient; but we should like to call attention to the experience of Dr. J. ELAM, as set out in our own columns a few weeks ago (THE LANCET, 1935, ii., 1253), in which particular attention was paid to the competence of the midwife to administer gas-and-air analgesia and to the cost of the case itself. At the Wellhouse Hospital, Barnet, midwives have been trained to use gas and air for their own patients, the only trouble met with in district work being to decide when to start the administration, a difficulty which was soon overcome in practice. Dr. ELAM was satisfied that the cost of nitrous oxide per case at Barnet was working out at about two shillings.

A NEW INSULIN COMPOUND

In treating endocrine deficiencies with glandular extracts it is not always easy to imitate the steady controlled secretion of the normal gland. Where the injected or ingested extract is stored in the body and used as required, as happens in thyroid therapy, no difficulty is experienced. But more often the available extracts have only transient effects, and when in addition the preparation must be given hypodermically serious obstacles may arise; for a point is reached at which the patient will revolt against a life punctuated by too frequent pin-pricks and will prefer his deficiency as the lesser evil.

The treatment of diabetes mellitus with insulin is a case in point. The average diabetic needs two daily injections of insulin and a considerable number require three; but few patients would tolerate more. Since the action of insulin is limited to a few hours the humane physician is usually forced to give larger doses of insulin than the immediate level of the blood-sugar would indicate. His patient accordingly oscillates between glycosuria with its attendant threat of ketosis, and the less dangerous but decidedly unpleasant state of hypoglycaemia. More than one attempt has been made in the past to avoid this difficulty by delaying the absorption of injected insulin. Some years ago LEYTON¹ tried powdered insulin suspended in castor oil and showed that the latter hindered the absorption of insulin and smoothed out the grosser oscillations of the blood-sugar. But the oily vehicle is only very slowly dispersed (by phagocytosis) and the risk

¹ Leyton, O.: THE LANCET, 1929, i., 361 and 756.

of local infection is increased. Recently Prof. HAGEDORN and his associates in Copenhagen have attempted to solve the problem by combining insulin with various organic bases to form compounds which are relatively insoluble at the pH of tissue fluids and are accordingly more slowly absorbed. HAGEDORN has just published some of his preliminary results² and ROOT and others³ have reported their experiences with samples of the same preparation, supplied by Prof. HAGEDORN. The preparation in question, protamine insulinate, is made by mixing a solution of insulin hydrochloride with a protamine extracted from the sperm of a species of trout, *Salmo irideus*. The insulin combines with the protamine base to form a compound which is least soluble at pH 7.3, that is, about the reaction of normal plasma. When this mixture is injected into a normal subject evidence of considerable delay in absorption is observed. Compared with ordinary insulin the fall in blood-sugar is much more gradual, and although the degree of hypoglycæmia obtained is rather less, the effect persists for about twice the usual time. Exactly similar differences are observed in diabetic subjects. Here the effect is greatest in those patients who are rather sensitive to insulin and whose blood-sugar under orthodox treatment displays big oscillations. Protamine insulinate smooths out the peaks and depressions to a remarkable extent, and the excretion of sugar and also of ammonia (an index of acidosis) is greatly reduced.

The charts shown by both the Danish and the American workers leave no doubt in the mind of the reader that combination with protamine greatly delays the action of insulin. This is an important advance, but we cannot yet assess its practical significance. A number of incidental problems must first be studied. For instance, the blood-sugar of the diabetic usually reaches its highest level in the period preceding the first meal of the day. The morning dose of insulin has therefore not only to reduce this level, but also to balance the carbohydrate eaten at breakfast. It has been found that protamine insulinate is not absorbed quickly enough to serve this double purpose, and it has been found advisable to use ordinary insulin for the morning dose, reserving the protamine compound for the evening, where a prolonged rather than an intense effect is desirable. That, of course, means that the patient would have to carry two kinds of insulin, and his daily routine is already complicated enough. Moreover the present preparation does not remain stable indefinitely and the suspension must be shaken before the syringe is filled. Finally, the new compound seems to be contra-indicated in diabetic coma where rapidity of absorption is vital. None of these difficulties is necessarily insuperable and the further researches of Prof. HAGEDORN and his colleagues will be awaited with keen interest. Meanwhile it is necessary to point out that the work is still in the experimental stage.

PROSTATIC INVOLUTION

HOWEVER much we may pride ourselves on the advances made in prostatic surgery during the last ten years prostatectomy remains a formidable operation, and it is worthy of note that medical men who have recommended the operation to their patients sometimes show a disinclination to undergo it themselves when they begin to find micturition difficult. Any treatment that holds out a hope of saving an elderly man from the dangers and discomforts of a major surgical operation deserves consideration. Dr. PAUL NIEHANS, in an article which appears on p. 307 of this issue, claims to have given relief to nearly 400 sufferers from prostatic enlargement by the simple operation known as Steinach's ligature II. In his opinion senile changes in the prostate are due to the removal of the inhibiting action of the hormone secreted by the seminiferous tubules and the unrestrained action on the prostatic tissues of the secretions of the interstitial cells of Leydig and of the basophil cells of the anterior pituitary, together with the female hormone which is known to exist in men as well as in women. This endocrine view of prostatic enlargement was anticipated many years ago by Mr. KENNETH WALKER in a Hunterian lecture which was published in our columns.¹ Mr. WALKER then stated that, although it was not known what determines the onset of prostatic enlargement, the enlargement was undoubtedly an incident in the involution of the genital tract. In all probability, he added, it was brought about by an upset in the endocrine balance occurring at the time of the male climacteric. Since that time great advances have been made in our knowledge of the hormones regulating sexual activity and of their interaction with the secretions of the pituitary body; and it is now established that the pituitary plays a very important part in the changes occurring in the endocrine system at the time of genital involution. Dr. NIEHANS summarises recent work on this subject, and whatever may be the value of the method of treatment he advocates we may well admit that senile changes in the prostate will ultimately be explained in terms of endocrinology.

After reviewing former attempts to deal with enlargement by such means as castration and vasoligature, Dr. NIEHANS relates how in 1928 he made use of the method of ligaturing the efferent ducts of the testis that had previously been employed by STEINACH as a means of "rejuvenation." He postulates that by occluding these ducts the hormones of the germinal epithelium are forced through the pores of the tunica albuginea into the numerous veins surrounding the testicle, and thence pass into the general circulation. Since these hormones inhibit the action of the various secretions responsible for senile changes in the prostate, any increase of them in the blood stream would have a curative effect. On p. 242 of our last issue is recorded the demonstration for the first time in

² Hagedorn, H. C., Jensen, B. N., and Krarup, N. B.: Jour. Amer. Med. Assoc., Jan. 18th, 1936, p. 177.

³ Root, H. F., White, P., and Marble, A.: Ibid., p. 180.

¹ THE LANCET, 1924, i., 16.

monkeys that male hormone can cause the disappearance of prostatic hypertrophy induced by oestrone. This would well account for the results following the ligature, when not only symptoms improved, but the size of the prostate diminished, and in the majority of cases residual urine disappeared. But what Dr. NIEHANS does not explain is why ligature of the efferent tubules should prove so much more effective than ligature of the vas. By either method the same result should be obtained—namely, cutting off the external secretion of the testis and increased absorption into the general blood stream. Yet vaso-ligature as a method of treating prostatic enlargement has proved a complete failure. Nor does he make it clear how ligature can revive the activity of the epithelium of the tubules. If the changes in the prostate are the result of involution in the seminiferous tubules, can it be supposed that occlusion of the efferent ducts stimulates their activity in addition to promoting absorption of their secretion?

Medicine however is not an exact science and the proof of the validity of Dr. NIEHANS'S observations should be sought in results rather than in deductions. Does ligature of the efferent ducts in fact relieve the patient of his symptoms, lead to a shrinkage of the prostate and the disappearance of the residual urine? In assessing the value of any method of treating prostatic obstruction it must be borne in mind that the symptoms of which the sufferer complains are liable to fluctuate. Periods of increased frequency and difficulty are followed by intervals of improvement, and care must be taken not to mistake one of these quiescent periods for an improvement that is the direct result of treatment. Moreover it is now certain that much of the difficulty in micturition experienced by a prostatic patient is the result of a dynamic rather than a static factor, that is to say, spasm of the sphincter rather than mechanical obstruction. Those who believe that Steinach's ligature II. acts through the sympathetic system, rather than by means of an alteration in the endocrine balance, may be right. But however disinclined urologists may be to believe that so simple a proceeding as that advocated by Dr. NIEHANS can cure prostatic obstruction, the mere fact that it is simple and can do no harm demands that it should be tried. If one man has been able to obtain such excellent results, others should have no difficulty in confirming them. The value of Steinach's ligature II. can readily be proved or disproved.

EPIDEMICS OF MALARIA

IN a paper read before the Royal Society of Tropical Medicine and Hygiene on Jan. 16th and expressly confined to the epidemiological side of malaria, Lieut.-Colonel C. A. GILL dealt primarily with the epidemic which began in Ceylon in the autumn of 1934. In any particular part of the area which this finally covered it broke out with such startling suddenness that its onset could be fixed to a day, the date being a month later in the southern than the northern

part. Thus in the town of Kurunegala, selected for intensive study for its convenient situation, the dispensary attendances were respectively 106 and 306 on Oct. 28th and 29th. This first wave had four morbidity but only three mortality peaks, set at about monthly intervals, the first morbidity peak bringing no corresponding rise in the death-rate. Further, as to children under 4, whose susceptibility to malaria is well known, there was an actual lowering of the percentage attending dispensary during the first wave and this was followed by no increase in deaths. These facts led GILL to the conclusion that the first morbidity peak was caused by relapses among older persons—a view strengthened by the reasoning that, had it been due to fresh infections, there must first have been a great increase in the numbers of infective *Anopheles culicifacies*, that such increase in infective numbers must have taken place from a human population still in its normal state of health, and that when infective the mosquitoes must have abstained from children's blood. There is no mention of any influx of persons not immune to the local plasmodial strains, so that GILL was left with a combination of two factors as the cause of the epidemic, the first being some influence on the plasmodium or its host making for relapse, the second the appearance of conditions favourable to multiplication of the mosquito carrier. As to the latter, he notes that there was a sharp rise in atmospheric humidity in October, 23 days before the onset of the first four-peaked epidemic wave, and another in April which in turn was followed by another epidemic wave. He also points out that during the nineteenth century malaria epidemics took place simultaneously in different parts of the world, that they were related to the cycle of sunspots, and that these last produce widespread abnormality of meteorological conditions. He showed a curve based on the seven and a half sunspot cycles which fell between 1860 and 1934, the most striking feature of which was the association of malaria pandemics with maximum or minimum sunspot numbers. These conditions of the sun are apt to be associated with drought or floods, and GILL pointed out that drought in a normally wet zone and flooding in a normally dry zone are likely to bring about conditions favourable to excessive breeding of mosquitoes. It was not however noted at the meeting that there may well be a nearer relationship between a changing quality of light and the occurrence of malaria relapse; EUGENE R. WHITMORE¹ has, for instance, shown that violet light produces relapse in the malaria of canaries, an infection which is due to another plasmodium, *P. relictum*. Colonel GILL was insistent on our powerlessness with our present knowledge, despite its great advance during the last fifty years, to prevent malaria epidemics, or to control them when they have begun. The need for further investigation was emphasised by his statement that the deaths in this outbreak were about 100,000, that the State relief measures

¹ Amer. Jour. Trop. Med., 1922, ii., 475.

cost £350,000, and that probably over a third of the island's inhabitants were infected, with consequent money loss, ill-health, and misery.

In discussion Sir RICKARD CHRISTOPHERS mentioned the likeness of the Ceylon epidemic to those in the Punjab in 1892 and 1908, the former the greatest ever recorded with 150,000 deaths, the latter covering an area greater than the whole of Ceylon. He described the maps of malaria epidemics as giving the instinctive feeling of "malaria cyclones"; a resemblance not merely superficial since their fundamental cause is meteorological, but still not the whole matter since happenings in previous years had their cumulative results. It was startling, he felt, to picture the sudden outburst of these epidemics as due to relapses, but Colonel GILL's contention needed serious consideration. The next speaker, Colonel S. P. JAMES laid particular stress on a possible widespread invasion of the area by infective anopheles, and said he thought that a relapse wave would imply a primary wave about eight months earlier. He urged the need for further research; especially since there is still no moderately complete account of the life-history of *A. culicifacies* in its adult stage, though it has been known for over thirty years as an important agent in the spread of malaria. Sir MALCOLM WATSON went outside the deliberately limited scope of the paper by dealing with endemic, not epidemic, malaria, and urged the primary importance of the house site in prevention. It was first necessary, he said, to select the proper site for a village and then to go forward with all that was necessary for good sanitation on that site. He insisted that to make the most of funds, first things must be put first, and held that this great epidemic showed that malaria was the major disease problem in Ceylon. Certainly this looks reasonable; nevertheless those who remember an effect of the great influenza pandemic of 1918 will hesitate to accept Sir MALCOLM's diagnosis without question; for at that time, among 14,640 persons who had been treated for hookworm infection² the death-rate per mille was 7.5, whereas among 3253 on the same estate who had been left untreated it was almost double, 13.8. An underlying cause of ill-health may be of greater importance than an evident cause of deaths. The further investigation which this speaker also urged is necessary before there are data for any firm conclusions; and in the meantime we suggest that the result of no constant drain on bodily reserves can safely be disregarded.

Prof. D. B. BLACKLOCK, in referring to the possibility of an epidemic of relapses, mentioned the work reported from Liverpool in the post-war years, which showed that treatment from July to December had a relapse rate of 38 per cent., while a similar treatment in January had one of 94 per cent. He dissented from the view that modern medical science was powerless to prevent and control these epidemics, and held that if the £350,000 spent on relief had been available for prevention the course of events would

have been very different. He spoke, then, essentially of endemic malaria, but he further pointed out the difficulty of dealing from that point of view with a free rural population in the tropics. Sir WELDON DALRYMPLE-CHAMPNEYS felt that, as put forward to the Royal Society of Medicine by Dr. R. BRIERCLIFFE and himself,³ the three most important factors in the causation of this epidemic were the encouragement of breeding of *A. culicifacies* in river pools left by the drying rivers, the fact that the population in the wet zone of Ceylon was little "salted" to malaria, and the semi-starvation of the people owing to partial failure of the paddy crop. He, too, urged the need for concentration on research, and was sure that remarks by Colonel GILL which had been taken as pessimistic were merely meant as pointers to lack of knowledge and stimulants to fill its gaps. Certainly all who commented on his paper were at one with the opener about the need for more intensive study of the problem of epidemic malaria. Colonel GILL has introduced a new and promising line of thought which is certain to be put to the test as soon as opportunity offers. His valuable paper and the informative discussion will be available in full in the coming issue of the Society's *Transactions* (vol. xxix., No. 5).

STANDARD BLOOD COUNTING APPARATUS

WE printed last week a request to hæmatologists from the British Standards Institution for criticism of a specification drawn up for counting chambers and dilution pipettes. This institution, which has done good work in standardising many technical processes used in commerce and engineering, has now turned its attention to the technique of the medical laboratory and has drafted a specification for a standard hæmocytometer. This contains no novelties with the exception that the ruling of the counting chamber embodies features of both the Neubauer and Glaubermann rulings, with one or both of which most workers are familiar. It is manifestly a good thing for laboratory methods to be standardised, so far as this is possible. Few people other than those actually engaged in laboratory work realise the wide divergence in results which may be obtained from the same specimen by the use of different techniques of examination; standardisation of method is the first step towards a valid comparison of results obtained in different laboratories. In selecting the hæmocytometer to start on the British Standards Institution has taken a relatively simple test object; even for this however the specification occupies ten foolscap sheets of typewriting and five sheets of line drawings. The specification is still only in draft form and the institution is anxious that before it is completed it should receive the consideration of all interested parties. Copies of the draft may be obtained on application to the director, British Standards Institution, 28, Victoria-street, London, S.W. 1.

ANNOTATIONS

ŒSTRIN AND CANCER

No branch of biological science shows such rapid progress as the study of sex hormones, and unlike advances in our knowledge of other series of pharmacologically active substances, this progress has covered all the aspects of the subject—physiological, pathological, and chemical. There is little doubt that the original stimulus for the work now developing so successfully was the observations of Allen and Doisy, some twelve years ago, which put research on the ovarian hormone on a sound experimental basis. A second great stimulus came through Aschheim and Zondek's recognition of œstrus-producing hormone and prolan in the urine. A year or so later, crystallisation of the former led to the foundation of the accurate chemical investigations in which so many have taken an active and important part.

Some of the most surprising results of this work concern the chemical relationships of the œstrus-producing hormones. Their recognition as derivatives of the sterol series has linked them up with vitamin D on the one hand and such substances as the cardiac aglucones on the other, and it is only natural that this chemical relationship should lead to speculation about the possibility of sex hormones having other actions besides the main one. It has been shown, for example, that many of the male hormone derivatives are œstrogenic, and Zondek's discovery of the œstrus-promoting factor in the urine of stallions indicates the complexity of the physiological activity of these bodies. The further observation that certain carcinogenic substances are also œstrogenic raises the question whether there is some relation between œstrin and malignant disease—a question of more than academic importance now that œstrin in substantial doses is widely used in medical practice. It has been claimed by a number of workers, particularly by Lacassagne, that it is possible to increase the incidence of mammary carcinoma by administration of œstrin, and it has also been pointed out that administration of very large quantities of œstrin will bring about changes in the epithelium of the genital tract of a type which suggest malignant proliferation, although no epitheliomata have been reported. Fortunately, however, we have the clear-cut demonstration, by E. L. Kennaway and his co-workers,¹ that œstrin, when painted on the skin of mice according to the standard technique employed by the Cancer Hospital workers in testing for carcinogenic properties, was entirely without effect. From this it appears that œstrin is not carcinogenic in the same way as 1:2:5:6-dibenzanthracene or methylcholanthrene are carcinogenic. It must be remembered also that the animals in which Lacassagne produced carcinoma of the breast were of inbred stock, selected for susceptibility to cancer, and that the conditions were therefore very different from those of administration of œstrin to human beings. Moreover, as Dr. Cramer and Dr. Horning pointed out in our last issue, all these experiments, including their own, involve the treatment of animals with large quantities of œstrin over a very long period, and here again the conditions do not resemble those of clinical practice.

In reviewing the relationship of sex hormones, carcinogenic hydrocarbons, and synthetic œstrogenic agents, Prof. E. C. Dodds² has lately remarked that

the similarity, in chemical structure, between carcinogenic hydrocarbons and œstrin is by no means so close as the similarity between the male and female sex hormones; yet there has never been any suggestion that the treatment of women with large doses of œstrin is likely to lead to masculinisation effects.

GONOCOCCAL EPIDIDYMITIS

THE frequency of infections of the epididymis secondary to gonorrhœa reflects unfavourably on the application of present methods of treating this disease. Various authorities place the incidence of this complication at from 2 to 25 per cent. of all cases of gonorrhœal urethritis, and the average is probably in the neighbourhood of 10 per cent. In fact, though nearly always preventable, it is by far the commonest of all intrascrotal infections. The way in which it is transferred nevertheless remains in dispute. There is little evidence to suggest a blood-stream infection; but the theories of spread through lymphatics or by surface continuity along the mucous membrane of the vas deferens have their advocates, while Pelouze¹ believes that infected material is forced down the lumen of the vas deferens into the epididymal tube—a belief widely shared in the United States. The aetiology of the condition, at any rate, is not in doubt. Trauma to the posterior urethra, in the presence of infection, is the almost invariable cause, and may result either from the patient's indiscretion or the doctor's mismanagement. Unfortunately it seems that the latter is often to blame. The posterior urethra may be damaged by the use of excessive pressure in urethral irrigations, by too frequent irrigation, or by fluid which is too hot or too strongly antiseptic, and a similar result may be produced by prostatic massage or urethral instrumentation carried out too vigorously or too early. On the other hand, the patient may cause or contribute to his own misfortune by sexual and alcoholic indulgence or by vigorous exercise, especially when the bladder is full.

Robertson and Lee² have recently described their methods in the treatment of 65 patients with epididymitis, in 90 per cent. of which the infection was known to be gonococcal. They emphasise the importance of avoiding this complication by care in treatment, and once it is established they advocate conservative methods, which proved successful in 63 of their 65 patients. The difficulty of achieving complete immobilisation of the scrotum by the ordinary methods of support, by suspensory bandage or jock-strap, is overcome by the use of an ingenious but simple application of strapping, which is a modification of that used in the Bellevue Hospital, New York City. The scrotum is brought forward to the suprapubic region and there immobilised, while at the same time the scrotal skin is protected from the irritating effects of the strapping by a layer of gauze, and in this way local applications of heat or cold are rendered unnecessary for the patient's comfort and there is no need of operation or admission to hospital. At the same time rest in bed for the first three days is advised. The indication for operation is the persistence of fever and acute pain at the end of this period, and the operation of choice is epididymotomy, which was performed in 2 cases.

The treatment of gonococcal epididymitis by

¹ Pelouze, P. S.: *Surg. Clin. North America*, 1935, xv., 213.

surgical incision and drainage has never found favour in this country, and the present support for conservative measures is therefore welcome. In the rare cases where surgical intervention has seemed advisable excellent results have been obtained by simple needling of the globus minor, accompanied where possible by aspiration of pus or inflammatory secretion.

INCENTIVES IN INDUSTRY

EXPERIMENTS recently carried out by C. E. Mace¹ were directed towards determining the efficacy of setting up standards of achievement as an encouragement in the performance of tasks or the learning of them. Measurement of results was necessarily adopted as a criterion of comparison between different standards, and conclusions emerged that should find application in industrial life. The investigation falls into place with other work, such as the study of the actual movements involved in a specific industrial activity, which is aimed at the attainment of optimum results consistent with the comfort and well-being of the worker, without which proviso there is more than a danger that opposition will be aroused against what is regarded as a process of "speeding up." The experimenter in this case is interested in the human side rather than the mechanical, and expresses his appreciation of the larger problems when he hopes that the incentives of industry may ultimately be assimilated more closely to those of professional life.

Industry has changed greatly since the bad old days when a worker was paid as little as possible and driven as hard as his physical powers allowed, his need for the necessities of life being regarded as sufficient incentive to work. That need will always be a primary urge to human endeavour, but man, for good or ill, is driven by so many other motives that industry is compelled to take account of them. It is a commonplace to lament the decay of handicraft with its gratification of the pride of achievement, which Mr. Mace calls upon in his experimental subjects; and to regret the repetitive processes that accompany mass production and appear to condemn workers to a day of monotony and boredom. Yet it is a discovery of industrial psychology that repetitive work need not be subjectively monotonous or inevitably accompanied by boredom; human nature is so adjustable that with reasonable conditions of work, including rest pauses, such tasks can be happily performed. Rest pauses were introduced, on obvious physiological grounds, to avoid fatigue, and increased output justified them. But some paradoxical results obtained by Elton Mayo suggest² that unexpected factors such as a sense of social solidarity in regard to one's fellows and the management of the firm, rather than diminished physiological fatigue, were the cause of the improved output in a batch of workers who were closely observed over an experimental period of two years. This observation indicates a trend of thought that is coming more and more to influence industrialists, who have passed beyond the stage when Factory Acts were necessary to ensure attention to material safeguards of the health of the worker, to sanitation, ventilation, protection against accidents, hours of juvenile labour and, in some cases, rates of pay; their chief function to-day is to protect standards from violation, not to establish them.

The human and social aspects of industrial organisation are now receiving attention, one sign of this development being the employment of industrial welfare workers in factories and similar establishments. In the beginning welfare workers were expected to supervise matters affecting the comfort and material well-being of employees—canteens, amusements, and the like; this they still do, but gradually there is emerging the principle that they serve as interpreters between the ideas of the administrative and employing side and the aspirations or even the dissatisfactions of the workers. An essential in the running of an industrial establishment is attention not only to the material but the emotional welfare of the employees, and in this way the difficulty of adjusting the human element to the demands of modern industry may perhaps be overcome. Welfare workers are now sufficiently numerous to have their own organisation and journal, and they are accumulating knowledge as to the mental attitudes and emotional reactions of individual employees which will fit in with the work of the Industrial Health Board and lead us nearer to the ideal of making the worker happy in his work; for this is, after all, the first condition for the successful working of any system of incentives.

BROMIDE INTOXICATION

OF late years several American observers have thought it well to call attention to the prevalence of bromide intoxication among psychotic, neurotic, and epileptic patients. To such patients bromide is often given for its sedative or anti-convulsive action, and mental symptoms due to too much bromide may pass unrecognised through being attributed to the disease that already exists. This is emphasised in a paper by Preu, Romano, and Brown¹ who describe what they term the symptomatic psychoses of bromide intoxication, and illustrate their description by details of nine cases. General retardation of mental processes, with anorexia and constipation, are well recognised as symptoms of bromism; but further intoxication may, according to these writers, give rise to insomnia, restlessness, disorientation, and loss of memory, followed by ataxia, tremor, and delirium. Refusal of food as well as food is common, and still further aggravates the condition, which indeed is most likely to occur in patients who are cachectic, short of fluid and chlorides, or suffering from renal impairment. Sudden onset of insomnia or delirium in a patient taking bromides should always suggest bromism, and the absence of skin lesions in no way negatives this suggestion. Diagnosis can be made with certainty only by an estimation of the bromide content of the blood. If this exceeds 250 mg. per 100 c.c.m., the mental symptoms can with confidence be attributed to bromide intoxication. Once the diagnosis is established the rest is easy. Bromide administration is stopped; fluids are administered in large quantities, together with 2 to 3 drachms of common salt a day; and under this treatment the symptoms rapidly disappear.

What dosage of bromide is likely to cause this condition? Unfortunately the evidence on this point is inadequate. In two of the cases the quantity taken was unknown; in the other seven it varied from 60 to 115 grains a day, generally for no very long period, but the doses may have been larger. General clinical experience would, indeed, lead us to suppose that they must have been larger, because

¹ New Eng. Jour. Med., Jan. 9th, 1936, p. 56.

very large numbers of epileptics in time past have taken much more heroic doses for prolonged periods without these ill-effects. It may be, however, as Preu and his colleagues suggest, that debilitated patients who for any reason are short of fluid, or whose blood is deficient in chlorides, will react in this unfavourable way to smaller doses. In any case the condition is one which the practising physician should keep in mind.

VASOMOTOR RESPONSES

In the current number of *Brain* Dr. E. Carmichael and his collaborators report the results of some recent investigations. Their intention was to test the functional capacity of the sympathetic nervous system in normal individuals and in patients suffering from various nerve lesions, particularly cases of hemiplegia. They sought first to ascertain whether there was any difference between the vasomotor response in the normal and paralysed limb.¹ Simultaneous temperature readings were taken from the cheeks and tips of the digits of the hands and feet by means of thermocouples, rectal temperature being also registered by this method. Changes in the temperature of the body were stimulated by the immersion of one or more limbs first in hot and later in cold water. The main outcome of these studies was the demonstration that if one or other foot is immersed in hot water the first change observed is a rise of rectal temperature, quickly followed by a rise in the temperature of both right and left hands, the curve of rise being identical for both upper extremities. On transferring the heated limb to a cold bath the temperature of the other extremities falls at once without any appreciable latent interval. The responses obtained in cases of hemiplegia are exactly the same as those obtained in a normal subject. In a further investigation² a more delicate method of estimating the vasomotor reaction was employed. A plethysmograph was applied to a finger or toe in such a way that a slight alteration in the volume of the enclosed digit could be recorded photographically by means of a tambour to which was attached a mirror reflecting a beam of light on to a moving strip of bromide paper. Slight changes in the volume of the digits could thus be continuously recorded. By this method the results previously obtained were amply confirmed and additional observations were made on the effect produced by various extrinsic and intrinsic stimuli. It was found, for example, that the sudden application of pain or cold to any part of the skin, or the occurrence of a sudden noise, produces an almost immediate fall in the volume of the digits in all limbs. This effect is also produced by voluntary deep breathing, by mental activity, and by visceral pain. It was shown that this effect still occurs when the normal blood-supply of the limb is entirely cut off by a tourniquet. In subjects from whom the sympathetic control to one limb has been either removed by operation or destroyed by injury this vasoconstrictor action fails to occur in the affected limb. Further, the stimulus is only effective if applied to a part of the body from which normal sensory nerve conduction is intact. When a painful stimulus is repeated the initial vasoconstrictor effect gradually passes off, even though the last stimuli are as painful as the first. The 23 patients suffering from lesions of the cerebral

hemispheres examined all showed responses exactly similar to those obtained with the normal subject. As the lesions in these patients involved between them all parts of the cerebral hemisphere the authors conclude that lesions of the cerebral hemisphere have no effect on the sympathetic vasomotor control of the extremities. They believe, however, that this control is dependent on the integrity of both pre- and post-ganglionic sympathetic fibres and on the integrity of the main sensory pathway from the point at which the body is stimulated. The sympathetic vasoconstrictor responses which occurred so constantly in these experiments were apparent in less than 4 seconds after the stimulus was applied. On the other hand, the vasodilator effects produced on warming the body only developed after the rectal temperature had begun to rise.

OWING to the death of King George the annual dinners of the Hunterian Society and of the Medical Society of London will not take place this year.

Mr. C. H. Fagge will deliver the Hunterian oration of the Royal College of Surgeons of England at 4 P.M. on Friday, Feb. 14th, his title being John Hunter to John Hilton.

OWING to inadequate response from candidates, optional translations from Latin and Greek will no longer be set in the membership examination of the Royal College of Physicians of London. More importance will be attached to the translations from French and German, and there will be a definite small allotment of marks for these in the total qualifying marks. They will however remain optional.

THE death occurred at St. Andrew's on Sunday, Feb. 2nd, of Mr. FARQUHAR MACRAE, consulting surgeon to the Western Infirmary, Glasgow, and the first secretary-inspector of the Indian Medical Council.

WE regret to announce the death of Mr. WILLIAM H. BATTLE, consulting surgeon to St. Thomas's Hospital, which occurred on Feb. 2nd, at Woking, Surrey. Mr. Battle earned high esteem from the medical profession both as general surgeon and as specialist in more than one important department, while to this journal he rendered valuable service as a collaborator for over twenty years.

INDEX TO "THE LANCET," VOL. II., 1935

THE Index and Title-page to Vol. II., 1935, which was completed with the issue of Dec. 28th, is now ready. A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

PORT REGIS PREPARATORY SCHOOL.—At this preparatory school two scholarships of £100 each are annually awarded to the sons of medical men. The school is at Broadstairs, Kent, and the scholarships were recently founded by Sir Milsom Rees. The next examination will be held on March 3rd, 1936. Candidates must be under 9 years of age at the time of competing, and the scholarships are normally tenable till the holder leaves the school. The holders will be selected at an interview in London from among those boys who have done best in some simple examination conducted in or near their houses. Applications for the scholarships must be addressed to the headmaster, Port Regis School, Broadstairs, from whom full particulars may be obtained. The applications must be made not later than Feb. 20th.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXXVII.—PROGNOSIS IN HEMIPLEGIA IN MIDDLE LIFE

HEMIPLEGIA occurs so often as a sudden event in the life of a person who has appeared to be in normal health and is actively engaged in his occupation that the question of prognosis is likely to arise immediately, a forecast being demanded both as to life and to return to activities. In general the prognosis as to life depends on the nature of the cerebral lesion and the vascular condition, while the return of function in recoverable cases depends upon a variety of other factors, not the least being the method of treatment adopted.

Causation

The great majority of hemiplegias result from vascular lesions — hæmorrhage, embolism, or thrombosis.

In my opinion a hæmorrhage sufficient to cause hemiplegia is nearly always fatal at the time or soon after. On the other hand a majority (probably from 60 to 75 per cent.) of victims of hemiplegia occurring between the ages of 40 and 65 from thrombosis or embolism survive the event. Estimation of the immediate prognosis depends, therefore, to some extent on detection of evidence of cerebral hæmorrhage, and a guarded one must be given unless this point has been settled. It cannot always be easily settled, nor is it of great immediate importance. If lumbar puncture has been performed, a hæmorrhagic fluid points strongly to cerebral hæmorrhage and to a fatal issue.

If a patient has retained or has fully recovered consciousness the questions which arise are the extent to which he will regain his normal health, and the likelihood of a recurrence of a vascular cerebral lesion. These questions depend upon the state of the vascular system, and will only be briefly summarised here. Hemiplegia from *embolism* is usually an accompaniment of mitral stenosis, and often occurs in patients whose myocardial function is adequate and who are capable of fairly normal activity for many years. In them the liability to recurrence must be considered. It is probable that a second stroke occurs only in a minority; at any rate there may be an interval of many years before it does so, and there are no means of foreseeing to which individuals it will happen. If a second embolus lodges in the opposite side of the brain to the first one the effects are more serious, since pseudo-bulbar symptoms will be produced in addition to the paralysis of the limbs. In cases such as these it is well worth while endeavouring to secure good recovery of motor functions; when the embolism occurs in association with auricular fibrillation or infective endocarditis the prognosis does not justify any serious effort in this direction.

The commonest cause of residual hemiplegia in middle life is *thrombosis*. Here the prognosis as regards recovery from the stroke varies very greatly, according to the cardiovascular condition. It is not nearly so unfavourable in middle life as in the elderly patients in whom it is often seen. In a certain number, however, even of those below the age of 60, an advanced state of arterio-sclerosis makes the prospect of recovery doubtful; further thrombosis may occur, or hæmorrhage may take place into the softened area. Hypertension which persists, or returns

after the stroke, not only increases the risk to life, but diminishes the amount of active treatment which is justifiable. These patients must be spared effort and inconvenience, both of which are necessary elements in a successful re-education.

There are, however, a large number of patients who make good recovery from thrombosis and live for many years in a satisfactory state of general health. In some of them the degree of vascular degeneration is remarkably slight, so slight that the cause of the thrombosis seems hard to explain. Most favourable of all are those in whom the lesion is a manifestation of vascular syphilis, which may respond well to treatment. The future of these patients depends on the extent to which muscular power and skill can be restored to the limbs, and more particularly to the hand. It is to the prognosis of residual hemiplegias of this type that consideration will mainly be given here.

Effect of Treatment

Some recovery of function in hemiplegia usually takes place spontaneously, but the final result is one of considerable disability, and falls far short of what may be achieved by suitable treatment. The ultimate outlook can therefore only be considered in conjunction with the mode of treatment adopted, and this should be made clear to the patient as soon as he is capable of realising it. The result in a case which is left to nature may be summarised by saying that the face recovers well, the leg fairly, and the arm badly or not all. The difference in improvement between the two limbs is mainly due to the fact that the sound arm can be used alone whereas the leg cannot; if this can be circumvented the improvement in arm and leg will be similar. In a neglected case the disability is often aggravated by contraction of joint-capsules and ligaments as well as by muscular contracture. If these occur they affect the prognosis unfavourably, as they are difficult to deal with satisfactorily.

The patient's conception of prognosis in hemiplegia is apt to be a gloomy one. He will quote the case of a relative or friend who lost the use of one side, who never recovered it, and for whom "the doctor said there was nothing to be done." If his medical attendant has clear ideas on the subject, is aware that the outlook for uncomplicated hemiplegia is potentially good, and can convince the patient of this fact, he may appreciably improve the prospect.

EXPLANATION TO THE PATIENT

In general the prognosis of hemiplegias, even of a favourable type, is not altogether good; many excellent recoveries are seen, but also many patients whose affected arm is of little use to them. The reason is that a considerable number of them do not obtain, or carry out, a suitable form of treatment, and this circumstance should not be allowed to obscure the fact that the prognosis in an uncomplicated case, treated from the outset on rational lines, is much more favourable. The situation may be represented to the patient as follows: *In the leg* it will probably be possible to prevent the formation of any deformity; he may eventually walk almost normally on the level, but will experience a slight

disability in going upstairs or a steep incline; once he has begun to walk the condition will continue to improve. Should spasm of the calf muscles prove more than usually intractable the result will not be quite so good, but can be improved by small orthopaedic measures. *In the arms* there will always be inequality in power, but the affected limb should become capable of use for most ordinary purposes. The grip may be only slightly reduced; extension of the wrist and fingers will be more so. The movement which is most likely to remain defective is supination, and herein lies the chief disability which he will encounter. He may, in fact, be able to lead the life of a middle-aged man in a fairly normal way.

It should be made clear to the patient that this result will not be brought about by drugs or any form of treatment which he undergoes passively, but may be achieved if he will submit himself for some weeks to a régime involving discomfort and tedious effort.

IMPORTANCE OF ACTIVE MOVEMENTS

Having indicated to the patient what he may reasonably hope for, it remains to assist him to bring about his recovery, and the next important factor in prognosis will be found in the extent of his willingness to coöperate. To expect him to make constant effort to use the paretic arm while the sound one is free is to make demands on memory and patience which will seldom be fulfilled. If the sound arm is immobilised by a bandage or splint, continuously at first and intermittently at a later stage, his attempts to use the paretic one will become reinforced by habit, many reflex movements will be performed unconsciously, and the arm will partake of the improvement which takes place as a rule in the leg. The only purely passive forms of treatment which are necessary are full movements of joints to maintain mobility, and to ensure positions of the limbs which will not permit of the formation of deformities.

In the leg, and to a lesser extent in the arm, the prognosis is affected by the duration of confinement to bed. It is much improved if his general condition permits the patient to sit in a chair for part of the day at an early stage, and if, by means of a wheeled frame, he is enabled to perform the movements of walking at a stage when the leg will not bear his full weight. If this treatment is persisted in, and supplemented by suitable exercises, the results are often remarkable, and a bad prognosis should not be given unless it has been tried. All cases do not respond alike, and in a few, although the spasm diminishes, muscular power does not show corresponding improvement.

In the cases considered so far treatment on the lines described has been instituted from the start, before the initial flaccidity has been replaced by spasm. There are, however, many patients in whom this has not been done, because their minds and those of their relatives are set on other measures. A large number obtain faradic stimulation, by which spastic muscles are goaded to further spasm while the re-establishment of nervous paths is not promoted. Many others put their trust in prolonged courses of massage, which is in fact not indicated and diverts attention from measures of real importance. Practitioners will at times be consulted about the outlook in cases of this kind. In them it is always less favourable, but there is hope of improvement in any limb in which the range of passive movement is not restricted. When this range is restricted the question has become an orthopaedic one.

Complicating Factors

Uncomplicated hemiplegia has been considered above; the prognosis is often affected unfavourably by concomitant defects in neurones outside the pyramidal tract. The most important of these are expressed by psychic changes, which may be present in almost any form or degree. If they persist they may render successful treatment impossible. But their duration cannot be foretold; quite often they clear up with surprising rapidity after a few days, and they should not be regarded as contra-indications to the line of treatment referred to. Some of the best results I have seen were obtained in patients who were at first completely non-coöperative. In some of them it may be advisable to put the sound arm in a plaster. It will often be found that irritability in itself provides a stimulus for movement, and it is less to be feared than apathy.

Hemi-anesthesia, usually in the form of a diminution rather than absence of tactile and muscle senses, may accompany a hemiplegia; it impedes recovery to some extent by increasing the awkwardness of the paretic limb. In many cases, however, it undergoes spontaneous improvement, and it does not call for any modification of treatment.

The prognosis in hemiplegia is influenced to a considerable extent, though in different directions, by the side of the body affected. Right hemiplegia in right-handed individuals is more to be feared than left, because it is likely to be accompanied by aphasia, though in thrombosis this does not always happen. But it has been my experience that the prospect of recovery of motor function is decidedly better when the right side is affected. The greatest danger is that the hemiplegic will accept his disability and settle down to the use only of the unaffected arm. It is much more difficult to prevent him from doing so when the sound arm is the one which he uses by choice and by habit. From the purely motor point of view the best recoveries are seen in right hemiplegias, and the most favourable type of case is a right hemiplegia which has escaped aphasia.

NEILL HOBIHOUSE, M.D., F.R.C.P.,

Physician, Royal Free Hospital; Assistant Physician West-End Hospital for Nervous Diseases.

ABERYSTWYTH AND CARDIGANSHIRE GENERAL HOSPITAL.—It is proposed to build an entirely new block to this hospital on the site now occupied by the women's ward. A sum of £25,000 will have to be raised to meet the cost of equipment and the provision of 24 more beds.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—For F.R.C.S. primary candidates a course of lecture-demonstrations in anatomy and physiology will be given on Mondays, Wednesdays, and Fridays at 8 P.M., from Feb. 24th to April 24th, at the Infants Hospital, and an evening clinical and pathological class for M.R.C.P. candidates at the National Temperance Hospital on Tuesdays and Thursdays at 8 P.M. from Feb. 25th to March 12th. The following courses will also be held: gynaecology, at the Chelsea Hospital for Women (Feb. 10th to 22nd); chest diseases, at the Brompton Hospital (Feb. 10th to 15th); thoracic surgery, at the Brompton Hospital (Feb. 24th to 29th); orthopaedics, at the Royal National Orthopaedic Hospital (March 9th to 21st). Week-end courses have been arranged as follows: children's diseases, at the princess Elizabeth of York Hospital (Feb. 22nd and 23rd); chest diseases, at the Brompton Hospital (March 7th and 8th); clinical surgery, at the Royal Albert Dock Hospital (March 14th and 15th). Full details may be had from the secretary of the fellowship, 1, Wimpole-street, London, W.1.

SPECIAL ARTICLES

MEDICINE AND THE LAW

A Conflict of Loyalties

In October last the German legislature passed an Act forbidding marriage between two persons one of whom is (1) suffering from an infectious illness which may seriously injure the health of the other or of the offspring; or (2) under guardianship for being a spendthrift or insane; or (3) is suffering from a disorder of the mind which would make the marriage "undesirable" in the public interests, or from a hereditary disease. The chief diseases which act as a bar to marriage are venereal disease and unhealed tuberculosis. In other infectious diseases it is for the doctor to make up his mind in each individual case whether there is a grave danger to health. In deciding whether a given marriage is undesirable he must treat it on its own merits. Dr. Schläger, in an article on the new Act,¹ points out that the doctor will in each case have to strike a balance between his duty of secrecy to his patient and his duty to disclose information in the interest of the community. The law binds him, when he can stop an undesirable marriage only by breaking his duty of professional secrecy, to put the public interest first. Naturally it is impossible to lay down any hard-and-fast rules which will fit every case. It is for the doctor ultimately to make up his mind just how much he thinks it necessary to disclose. He may go too far and commit a breach of the law which binds him to professional secrecy. In certain circumstances he might be found guilty of negligence.

German medical men thus have now placed upon them an extremely invidious duty. It seems to have no analogue, fortunately, in English law. Any English physician must notify certain infectious diseases and industrial diseases, but the hardship which this statutory breach of professional confidence may cause is not comparable to the injury which may be done to a patient who consults a doctor in good faith and then finds afterwards that the doctor has played the part of what amounts to a police spy in preventing a marriage which, apart from statute, is no concern of the doctor at all. Mr. Justice Avory tried in 1914 to throw upon doctors the duty of disclosing to the police any cases of abortion which they came across in their practice, and the profession has successfully resisted the imposition of such a repugnant duty. The position of the German doctor is the more difficult in that his duty of secrecy is not only a professional but a legal duty in a far stricter sense than in this country. Our colleagues in Germany are not to be envied the problems they will apparently have to face and the decisions they will have to make under this legislative venture.

Married Women and Doctors' Bills

The Law Reform (Married Women and Tortfeasors) Act of 1935, the relevant section of which came into operation last August, has made a radical alteration in the position of married women in respect of contracts and their liability to pay (amongst other things) the doctor's bill. Before that date a married woman was not personally responsible for her contracts. A judgment could only be obtained against her separate estate (*Scott v. Morley*, 20 Q.B.D. 120), and if she had no available separate estate the creditor

was unfortunate, because unless the married woman carried on business either alone or jointly with her husband she was not liable to be made bankrupt. A judgment summons was useless, for although her separate estate was liable, she was not personally liable to pay, and in order to obtain an order on a judgment summons committing a debtor to prison a personal liability to pay has to be proved. As a result of the protection given to married women, doctors, like other purveyors of necessaries, were in the habit of regarding them as contracting as agents for their husbands, and so making the husband and not the wife liable as she pledged her husband's credit and not her own. Whether a married woman contracted personally so as to make her separate estate liable or as agent for her husband was a question of fact. To the question "Whom did you trust, the husband or the wife?" the wise man always answered "the husband." Now he should think twice before giving a reply. If the wife has private means, it might be advantageous to regard her as contracting as principal rather than as agent, since judgments can now be enforced against her as if she were a *feme sole*. In cases where the worldly goods are in the wife's name—not an uncommon position in many households—the practitioner would be well advised to open the account in the ledger in the wife's name, rather than in that of her husband. There still however remains one snag, for if a testator by his will, dated prior to 1936, gives property to a married woman subject to a restraint on anticipation and dies after 1936, but prior to 1946, such property is not available for creditors. The practitioner might therefore be well advised to ascertain the date of his female patients' marriages.

Card Party for Medical Charity

In *Williams v. Trevor*, a case before Mr. Justice Finlay last week, the plaintiff claimed damages for the loss of a sum of £10,000 at a card party held at Sunderland House at the end of 1934 for the benefit of the Ivory Cross National Dental Aid Fund and the Royal Northern Hospital. He said that he had been invited to attend and that the defendant had assured him that the organisation of the party would be perfect and that everybody assisting would be personally known to the defendant or to members of the committee of the hospital. It was the plaintiff's complaint that the games (which included baccarat and *chemin-de-fer*) were unfairly played and that card-sharpers were present. Legally, Mr. Williams could establish no cause of action against Mr. Trevor unless there was some breach of contract or breach of duty. When the plaintiff's witnesses had been called and examined, the judge stopped the case. He found no breach of warranty. The letter of invitation to the card-party did not constitute a contract; it was not a warranty but a mere puff. Indeed, though the learned judge seems not to have gone into this aspect of the case, the law declines to recognise a social invitation as having contractual consequences. For instance, if A invites B to dinner and makes elaborate and expensive preparations for his entertainment, A cannot recover damages when B, having accepted the invitation, fails to appear. Mr. Justice Finlay was not quite sure what kind of duty (apart from contractual liability) the organisers of such a party owed to their guests. They must he thought, take reasonable pains to exclude undesirable persons; but he could not rule that there wa-

¹ Deut. med. Woch., Jan. 24th, 1936, p. 152.

any positive undertaking that no bad characters would find their way in. One of the risks and evils of such parties was the probability that undesirable persons would be present; everyone attending such a party must be aware of that risk. If Mr. Williams was to succeed, he must further prove damage arising out of the alleged breach of duty. But the evidence, said the judge, seemed to establish the contrary; Mr. Williams, early in the evening, suspected that there was cheating, yet he continued deliberately to play.

Mr. Justice Finlay is not a judge to chatter in court about extraneous matters. The more weight, therefore, attaches to his condemnation of this association of gambling with charity. He said he knew from personal experience how hard it was to raise money for charities; but he hoped that, after this case, no reputable charity would ever resort to so questionable a method of raising money. He quite appreciated that the patrons of the charities for whom the party was given knew nothing about it, but "such methods were to be severely discouraged." The jury associated themselves with his lordship's remarks, and there is every reason to believe that public opinion will agree.

Alleged Morphine Poisoning at Nursing-home

The inquest on Miss Ada Baguley, who died on Sept. 11th at a home in Nottingham, ended last week in a verdict that the deceased met her death by a fatal dose of morphine or heroin or both, and that the dose was feloniously administered to her by Ronald Sullivan and Nurse Waddingham who together conducted the home. The death certificate had originally stated that Miss Baguley died of cerebral hæmorrhage; post-mortem examination showed that this was incorrect. Mr. Baguley, father of the deceased, died in 1929, leaving an estate of £1600 to his daughter, subject to a life interest to his wife. Mrs. Baguley, the 87-year-old widow, died in the home last May. Miss Baguley, her daughter, described as a helpless cripple, had made a will bequeathing the whole of her estate to Nurse Waddingham and Mr. Sullivan in consideration of their looking after her and her mother. Nurse Waddingham at first denied having given the deceased morphia or having had any morphia in the house. Later she stated that she gave Miss Baguley morphia under medical instructions. Her evidence was in conflict with that of the practitioner who attended the deceased. Dr. Roche Lynch, recalled by the coroner, had expressed the opinion that a dose from one grain upward of the morphia preparations mentioned during the inquest would be a positive fatal dose. The chlorodyne medicine which Miss Baguley had been taking would not, he said, have given her any marked tolerance of the drug. He considered that a fatal dose of morphia must have been administered within six to twelve hours of death.

SCIENCE AND INDUSTRY

THE Department of Scientific and Industrial Research has many activities, most of which are unconnected with medicine or surgery, but all have a close bearing on human life and progress. Some account of these researches is given in the annual report of the Department for the year 1934-35 (H.M. Stationery Office, Cmd. 5013, 3s.).

The protection of X ray workers from gamma rays, by remoteness and shielding, has been investi-

gated, and the conclusion is reached that it is undesirable for the personnel to remain in the immediate vicinity of patients undergoing treatment with large quantities of radium. The investigators point out the high degree of protection attainable with properly designed radium safes, the necessity for expeditious bench manipulation of radium containers, and the superiority of bulky postal transport boxes with only moderate lead shielding over small containers utilising the maximum lead shielding possible.

The Food Investigation Board has investigated the destruction of bacteria in meat by α , β , and γ rays and with β particles from radon. In both cases disinfection goes on at the same rate within a very long range of temperature. The effect of varying oxygen pressure on the rate of oxidation of hæmoglobin to methæmoglobin, besides being of theoretical interest, is of importance in the practical problem of the bloom of gas-stored meat and fish. An interesting research was made into the retarding effect of iodised paper wrapping on the rotting of certain fruits.

Fundamental standards, however unattractive to the unlearned, form bases for all exact scientific knowledge, and the National Physical Laboratory has redetermined the freezing point of platinum, obtaining a value (1773.3° C.) in agreement with the results recorded at the national laboratories of Germany and the United States, within the limits of accuracy obtainable at present; other freezing points up to that of iridium (about 2450° C.) are being redetermined. Close agreement with the Physikalisch-Technische Reichsanstalt in the definition of the metre in terms of the wave-length of the red radiation of cadmium has been reached, making this fundamental unit independent of all existing standards.

The various trade research associations have been active in the investigation of problems arising directly out of industry, and perusal of the report should convince readers that the Department is doing fine work in coördinating researches which, directly or indirectly, add to the comfort or safety of civilised life. The measurement of noise, for instance, may eventually lead to the suppression of unnecessary noises—a matter of the greatest interest to all who have the care of the sick. The medical practitioner is likely to find in the report hints towards solving the increasingly complex problems of diagnosis, treatment, and régime. The volume is inexpensive and is not heavy reading.

THE TROPICAL HOUSE

AN OBJECT-LESSON AT LIVERPOOL

INSTIGATED by Prof. D. B. Blacklock, the Liverpool School of Tropical Medicine has rented a piece of land adjacent to the city for the purpose of building small replicas of houses used in different parts of the tropics. The aim of the model is to illustrate the actual disease-producing conditions which exist in each type of defective dwelling along with such simple methods of dealing with defects as can readily be put into operation. This enterprise may not be very remarkable in itself. Models of unhygiene at home and abroad can be found in museums and other instructive places. But what is remarkable is the conviction of Prof. Blacklock and his group that something effective can be done about it, for the fatalistic belief still widely rules that people, and especially native races, get the houses they deserve.

It is no new idea that houses in our tropical dependencies breed disease. Sixty-five years ago Surg. Major David Boyes Smith, then sanitary commissioner of Bengal, wrote as follows:—

“The people live in villages which appal the sanitarian. Every revolting abomination conceivable is to be met with in these villages—obstructed ventilation, corrupted ground, polluted atmosphere, putrid organic matters, faecal gases, the revolting water tank, with consequent sickness, debility, degeneration and cachexia of the people,”

and in a Chadwick lecture last year¹ Prof. Blacklock, who cited this appalling word-picture, went on to enumerate the many diseases still directly traceable to defects in housing, indicating categorically those diseases which could be avoided by proper selection of site and of material for construction. In our own rural areas bad housing chiefly connotes such defects as inadequate lighting, dampness, draughtiness, or, what may be worse, lack of ventilation and inadequate air space, and the diseases connected with these defects—rheumatism, bronchial catarrh, and tubercle—though important enough, are relatively few in number. In our urban areas structural defects provide lodgement for vermin, while bad ventilation and overcrowding facilitate the spread of epidemic disease, largely by droplet infection. While all this is serious enough, the problem of domestic hygiene in a temperate climate is simple in comparison with the prevention of the variety of diseases due directly to the type of housing in places where the air is always warm and moist. In the tropics the site of a house selected in ignorance of the dangers from anopheline breeding-places may result in constant malaria with its consequent anaemia, fever, and repeated interruptions of agricultural work. The foundations, floor, and walls of a house composed of dried mud or mud bricks are likely to be the source of relapsing fever and many other infections. The materials of which the roof is composed may conduce to the spread of bubonic plague in endemic areas. These relations of cause and effect were set out three years ago by Prof. Blacklock, entitled “The House and Village in the Tropics” (London, 1932. 3s. 6d.), which contains among much serious argument an entertaining chapter on the skin of the native child who from the hour of its birth upwards is subjected to a perpetual series of injuries and pin-pricks of every kind—an aspect of tropical medicine to which too little attention has so far been paid.

The conviction is growing that in many parts of the hot regions of the world the reform of housing methods would mark a definite advance in the prevention of disease, and the Liverpool enterprise is to be welcomed as an agent in putting these ideas into practical form. Students who come to Liverpool to study tropical hygiene, professional and business men going out to live in the tropics, may see for themselves some of the manifold ways in which danger to the health of the tropical household arises. While no doubt research is needed into the best methods of house construction and into the choice of materials for building, the object-lesson at Liverpool should afford the stimulus to such research and the incentive to apply it.

¹ THE LANCET, 1935, i., 526.

STAFFORDSHIRE GENERAL INFIRMARY.—The general committee of this hospital have decided to begin work on extensions which will include a new ward for private patients, a new general ward, and a children's ward. X ray, massage, and electrical departments are also to be built.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Capt. A. T. Rivers placed on Retd. List.
Surg. Lt.-Comdr. P. B. Jackson to *Drake* for R.N.B.
Surg. Lts. D. Simpson to *Halcyon*, P. K. Fraser to *Aphis*, H. E. B. Curjel to *Carlisle*, and D. Chute to *Curlew*.
The Gilbert Blane Gold Medals for 1935 have been awarded to Surg. Lt.-Comdr. A. A. Pomfret, R.N., and Surg. Lt.-Comdr. W. G. Fitzpatrick.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. J. D. Lendrum to *Pembroke* for R.M. Infirmary, Chatham.

ARMY MEDICAL SERVICES

Maj.-Gen. J. P. Helliwell, C.B.E., late A.D. Corps, retires on ret. pay.

Maj.-Gen. J. P. Helliwell, C.B.E., late A.D. Corps, relinquishes the appt. of Dir., Army Dental Serv., War Office.

Col. J. V. M. Byrne, late A.D. Corps, appointed Dir., Army Dental Serv., War Office. (See also THE LANCET, Jan. 4th, 1936, p. 42.)

ROYAL ARMY MEDICAL CORPS

R. Hospital, Chelsea.—Maj. J. B. Fotheringham, M.B., R.A.M.C., relinquishes the appt. of Dep. Surg. Maj. E. M. Townsend, M.C., R.A.M.C., to be Dep. Surg.

Temp. Commissions: Capt. A. F. Campbell to be Maj.; R. B. Grey, J. Shields, and P. W. Dill-Russell to be Lts.

ARMY DENTAL CORPS

R. J. Godfrey is granted a temp. commn. in the rank of Lt. (*Vide* also Army Medical Services.)

REGULAR ARMY RESERVE OF OFFICERS

Capt. W. G. Burns resigns his commn. and retains the rank of Capt.

TERRITORIAL ARMY

Capt. P. Dwyer to be Div. Adjt. 50th (Northumbrian) Div., vice Capt. P. F. Palmer, vacated.

Capt. J. J. O'Dwyer to be Divl. Adjt., 55th (W. Lan. Div.), vice Maj. J. H. Bayley, M.C., vacated.

Capt. J. G. Black to be Divl. Adjt., 43rd (Wessex) Div., vice Maj. J. E. Rea, vacated.

Capt. R. V. Powell to be Maj.

J. C. H. Speirs to be Lt.

R. M. H. Anning (late Cadet, Epsom Coll. Contgt., Jun. Div., O.T.C.) to be Lt.

ROYAL AIR FORCE

E. B. Harvey and D. S. MacL. MacArthur are granted short service commissions as Flying Offrs. for three years on the active lists.

D. W. I. Thomas is granted a short service commission as a Flying Offr. for three years on the active list and is seconded for duty at St. George's Hospital, London.

RESERVE OF AIR FORCE OFFICERS

Flying Offr. T. P. Mulcahy relinquishes his commission on appointment to a commission in the Indian Medical Service.

INDIAN MEDICAL SERVICE

Majs. to be Lt.-Cols.: P. Verdon, D. V. O'Malley, O.B.E., and S. A. Phatak.

S. W. Allinson to be Lt. (on prob.).

Lt.-Col. W. D. Keyworth retires.

Indian Medical Department.—Maj. (Sen. Asst. Surg.) R. S. Keelan retires.

ROYAL MANCHESTER CHILDREN'S HOSPITAL.—A year ago this institution launched an appeal for £100,000 for the maintenance of the convalescent home, to add a wing to the nurses' home, and for other necessary extensions. A good start was made and in the first four months after the appeal was issued £10,000 was collected, but the £30,000 figure has not yet been reached.

CORRESPONDENCE

IS COUSIN MARRIAGE DANGEROUS?

To the Editor of THE LANCET

SIR,—There has long been a vague belief that human inbreeding is undesirable, and some unions of blood relations are forbidden by law. Recent research has shown that certain diseases are vastly commoner among the offspring of blood relations than in the general population. In Western Europe, marriages of first cousins rarely amount to more than 1 per cent. of all marriages. The following percentages of first-cousin marriages have been found among the parents of patients with certain diseases:—

	Per cent.
Xeroderma pigmentosum (Siemens's data, after 1906 only)	47
Retinitis pigmentosa (Usher's cases)	27
Juvenile amaurotic idiocy (Sjögren's cases)	15
Ichthyosis congenita (Cockayne's data)	14

These examples might be considerably multiplied. Unfortunately, however, research into rare diseases gives us little idea of the importance of the phenomenon for general health.

The fact that the children of first cousins are some thirty times more likely to develop retinitis pigmentosa than the general population does not tell us whether abnormalities of this type (in genetical language, due to rare autosomal recessive gene substitutions) are sufficiently common to render cousin marriage undesirable. Animal experiments give no clear answer. In some species the inbreeding of members of wild populations leads to the appearance of numerous recessive abnormalities. In others it does not. For this reason the Committee on Human Genetics appointed by the Medical Research Council have obtained the coöperation of hospitals in a large-scale inquiry on this question. All patients in the participating hospitals are being asked whether their parents were related, and if so how. It was thought that any less comprehensive inquiry would be worthless, since the data on animals suggest that not only congenital abnormality but liability to certain infections or degenerative diseases might be due to recessive genes.

The preliminary results are distinctly encouraging. Certain rare conditions seem to be rather commoner among the progeny of related than among those of unrelated parents. Nevertheless, the results will not be statistically significant until at least three times the present number of cards have been completed. It is particularly desirable to obtain more data regarding children; and from country districts, where more inbreeding occurs than in towns. While, therefore, the Committee acknowledge with the utmost gratitude the assistance so far given by hospital staffs, they hope that the same efforts will be continued until really adequate data are available. The coöperation of additional hospitals would also be most welcome.

I am, Sir, yours faithfully,
London, Jan. 31st. J. B. S. HALDANE.

MALARIA EPIDEMIC IN CEYLON

To the Editor of THE LANCET

SIR,—In your account of the discussion at the Royal Society of Medicine on Nov. 16th (THE LANCET, 1935, ii., 1176), which has only recently been brought to my notice, there is room for misunderstanding in the remarks attributed to me. I should be grateful if you would allow me to explain my position. Your report runs: "He (myself) agreed with the use of

atebrin *only in hospitals* (my italics) in Ceylon, but thought that this drug would prove to have many advantages owing to its better and more rapid absorption and action. He was sorry that it had been rather pushed into the background." This statement implies that in an epidemic the use of atebrin should be limited to institutional cases solely. Nothing could, in fact, be further from the truth, for it is widely known to-day that peroral atebrin is a well-tried routine remedy in all conditions. Actually in the paragraph quoted above, I was referring to *atebrin musonate*, the new salt of atebrin which is given by injection, and which, being in a trial stage at the time of the epidemic, was suitable only for hospital cases. In my speech I followed up these remarks on atebrin musonate by saying:—

"I am sorry to note that the exaggerated idea of using atebrin musonate as a panacea in all cases has caused the peroral treatment of atebrin to be relegated into the background. . . . Suitable administration of atebrin has availed to reduce the relapse rate and sequelae. . . . A treatment combining atebrin and plasmoquine, the drugs given according to a strict schedule on certain days of the week, is very promising, but where there is a floating population it is advisable to give atebrin alone."

I think this quotation should make my views reasonably clear.

I am, Sir, yours faithfully,
Elberfeld, Germany, Jan. 31st. W. SCHULEMANN.

CONTROL OF MEASLES

To the Editor of THE LANCET

SIR,—I have no desire to enter into competition with Dr. Copeman when he claims to have been the first person to introduce into this country the modern method of prophylaxis and attenuation of measles by means of convalescent serum. At the same time, it may interest him and others to know that, mainly due to the stimulus of the late Dr. Claude B. Ker, convalescent measles serum was used in the Edinburgh City Hospital between the months of February and September, 1924. I was then senior assistant to Dr. Ker, and was his collaborator in this experimental work of attempting to immunise measles contacts in certain wards of the hospital. Unfortunately the findings were not published, partly owing to the fact that I left the hospital to take up another post, but mainly owing to the death of Dr. Ker a few months later. The figures seemed too few to publish as a paper, but a few notes may be of interest—even if somewhat belated.

During the month of January, 1924, I took some blood from several adult measles patients who happened to be admitted to the hospital. The blood, taken off about ten days after the rash, was allowed to clot and the serum was pipetted off and a small percentage of phenol added. In that month ward 7 became infected by an incubating case—introducing measles to the ward. The child was probably infectious for three or four days before being removed on Jan. 21st, on which day also another child from the same school occupied a bed on the other side of the ward for a few hours and was diagnosed measles and removed. Of the other 23 children in the ward, all but 7 had a history of measles; of these 7, 2—one in the next bed to the first case, and the other roughly opposite and three beds away from the second case—were protected by 3 c.cm. of convalescent measles serum. Neither took measles, whereas 4 of the remaining unprotected 5 took measles on Feb. 2nd, 4th, 4th, and 6th respectively.

From the infectious cases above mentioned, treated in side wards, infection was apparently carried to ward 7A

where a small boy developed measles and was isolated on the appearance of his rash on Feb. 14th. Of the 14 children in the ward, 4 had not had measles; all were protected on Feb. 14th. None took measles definitely, but one child on Feb. 26th had a flick of temperature—no catarrh or Koplik's spots—then remission of temperature, and on March 1st a definitely morbilliform rash and a rise of temperature to over 100° F. for one reading. This seemed to have been a case of abortive or modified measles.

In May, 1924, a boy with whooping-cough was admitted to ward 20 and on the next day (May 24th) was isolated for a measles rash which had come out in the night. The exposure of the contacts was in all about 16 hours. The ward contained 15 children, of whom 8 had not had measles. The 8 children received 3 c.cm. of convalescent measles serum on May 25th, nearly 48 hours from the first exposure. None of these children took measles.

Convalescent measles serum was given in several other wards during the summer of 1924, and attenuation of the disease was noticed in many of those measles contacts injected. In one particular case the prodromal period lasted seven days before the rash appeared, and the incubation period in many instances was as long as the twentieth day and once (apparently) the twenty-fourth day, although this was a very doubtful case. During August, 1924, cases of measles occurred in Victoria Park House, a children's home in Edinburgh, and I was asked by the then medical officer of health, Dr. Robertson, to give the contacts some convalescent measles serum. Ten of the 20 children who were contacts had not, according to the history, had measles, but 10 who gave no history of having had the disease were protected with 5 c.cm. of the convalescent measles serum. None of these children took the disease.

Another experiment which was not, however, so successful was carried out in a certain ward of the Craiglockhart Hospital, a poor-law institution near the City Hospital, where an epidemic of measles had broken out among children mainly under two years of age. The serum was given late in the incubation period. Out of 11 contacts who had not had measles, 8 took the disease and 5 of these died later in the wards of the City Hospital to which they were moved.

It could be deduced from these experiments that, if given early enough, convalescent measles serum was of value, not only in preventing but in attenuating the disease.

I am, Sir, yours faithfully,

JOHN MCGARRITY.

Little Bromwich Hospital, Birmingham, Feb. 3rd.

LONDON HOSPITAL CATGUT

To the Editor of THE LANCET

SIR,—A report of an inquest at Cambridge appeared recently in the lay press in which it was stated that death was due to tetanus, and the house surgeon in giving evidence said that he agreed that the infection was from the catgut. There was also in the report the direct implication that the catgut had been supplied by the London Hospital.

This is incorrect. I have been in communication with the secretary of the hospital at which the death occurred, and he writes: "I am glad to be able to inform you that the suspect catgut was not London Hospital catgut." I might add that since the publication by the Medical Research Council in 1929 of the results of the long investigations carried out at this hospital by Prof. Bulloch, in collaboration with Dr. Lampitt and Mr. Bushill, into the "Preparation of Catgut for Surgical Use," the demands for London Hospital catgut have increased very considerably, and we now supply catgut all over the world.

I am, Sir, yours faithfully,

ARTHUR G. ELLIOTT,

House Governor, London Hospital.

Whitechapel, E., Feb. 3rd.

PREMATURE BURIAL

WE have received the following communication: "The Society for Prevention of Premature Burial, founded in 1896, has for its object the reform of the law relating to the granting of death certificates. Until the beginning of this year the Society existed as an independent body, but it is now affiliated with the Council for the Disposition of the Dead Inc., one of whose basic objects is the revision and the codification of the laws relating to death. The Council now have in hand a Bill for the registration of funeral directors. This affiliation has a twofold purpose, (1) the machinery necessary for the reform is strengthened, and (2) overlapping is eliminated. But the internal policy and expenditure of the Society for Prevention of Premature Burial continues, and while informing the public of this affiliation we would like to take this opportunity of seeking further interest and support. Funds and increased membership are earnestly desired. All inquiries should be addressed to the secretary of the Society, 30, Castelnau-gardens, Barnes, London, S.W. 13."

This letter is signed by Major Reginald Austin (R.A.M.C., ret.), Dr. Jane Hawthorne, Dr. J. Lachlan-Cope, Miss Maud Yandell, and Miss Lettice Macnaghten.

PANEL AND CONTRACT PRACTICE

Defaults in Clerical Work

PERSONAL difficulties, encountered in panel practice, are from time to time illustrated by the reports of inquiries (under the Medical Benefit Regulations) into the efficiency of the service rendered by a particular doctor. A recent case from Lancashire shows that his shortcomings can be admitted with frankness by the practitioner and treated with sympathy by the authorities concerned. Between 1925 and 1934 sums amounting to a total of £123 were withheld by the Minister from the moneys payable to the insurance committee, and a corresponding amount was recovered by the committee from the remuneration of the doctor, for the following breaches of the terms of service: failure to furnish divisional and

regional medical officers with the required information on Forms R.M.2; failure to keep proper medical records; failure to return to the committee on request the medical records of insured persons removed from his list; and issue of prescriptions on the official form of the committee to persons not on his panel list. The doctor received formal warnings from the Minister on four occasions during 1928 and 1929. A year ago the medical service subcommittee reported on the failure to furnish on request the records of removed patients, and the withholding of the sum of £75 was recommended. Meanwhile, no medical records of insured persons had reached the committee from him since Oct. 1st last, though he undertook a year ago to return all outstanding records within a week or so. No acceptances of insured persons had

reached the committee from him since last September. In March last year the clerk to the insurance committee asked for particulars as to prescriptions issued by him in the previous October, November, and December to persons not on his register; reminders were sent, but elicited no information. These complaints offered considerable material for the allegation that his conduct as a panel practitioner had been such as to bring panel practice into disrepute and that he had repeatedly infringed the terms of service.

The doctor frankly admitted his omissions and stated that he had been treated at all times with great consideration by the committee. While allowing himself the extenuation, if such it be, that he had a natural dislike for clerical work and a "mistaken but stubborn notion that the essential business of a medical practitioner is solely the treatment of ill-health," he candidly confessed his faults but claimed that, at the end of 1933, he had fully appreciated the duty of better clerical work and had then made a great effort to bring his record cards up to date. In 1934 he had cause to be seriously anxious about his own health, and he diagnosed early pulmonary tuberculosis. He acquired an open-air shelter and lived the complete sanatorium life in the grounds of

his house, keeping up his visits and attendances on patients but sacrificing everything else to the recovery of his health. He was now able to report a marked improvement in his physical condition. He could claim that he was not a man of vicious habits, and that the clerical side of his private practice had been as badly neglected as the records of his panel work. He stated that he had found paid secretarial help disappointing. At the inquiry he had to admit that 33 cards had still not been returned. The inquiry committee briefly reported that the doctor excused himself in the manner already described but called no evidence of his state of health; he had stated that his sputum was examined by the tuberculosis officer of the county in October, 1934, with negative results. The inquiry committee summed the matter up by saying that, even accepting the doctor's own evidence of his health, it found no sufficient excuse for his continued neglect of his duties. The Minister of Health announces that, after considering the report and taking into account the evidence of the practitioner's personal character and professional standing, he has decided not to remove his name from the medical list of the insurance committee. He makes no order as to the costs of the inquiry.

PUBLIC HEALTH

Mental Hospitals in London

AMONG the many tasks of local government, the care of the mentally affected has become more prominent as it has been exercised with more thoroughness and unity of control. Nowhere better than in London can one see that this duty is a heavy one and that it may be carried out in a spirit of enlightened generosity. A recent report¹ describes many activities in connexion with the 33,000 mental patients for whom the London County Council is responsible. The report deals separately with the mentally disordered, and with the defective patients the majority of whom were until 1930 under the administration of the Metropolitan Asylums Board.

MENTAL DISORDER

For the mentally disordered nearly 700 more beds are being provided, according to plans approved during 1934, and there was also contemplated an additional 360 beds at Ewell. For these and other works an expenditure of £31,000 was authorised; further large sums are being spent on the modernisation and better equipment of individual hospitals. The figures published in this report indicate that voluntary treatment is being more availed of; at the beginning of 1935 the number of voluntary patients in residence was 18.5 per 1000. As the public and those concerned with certification come to realise better that voluntary treatment is permissible and advantageous for many of the certifiably insane, it is probable that the number of direct referrals of voluntary patients will continue to rise and the number of certified patients to fall. The voluntary patients in the mental hospitals cannot in London be considered without regard to the Maudsley Hospital, which during 1934 dealt with nearly 1000 in-patients, all of them by its constitution on a voluntary basis. In its various out-patient departments, including those in North London, 4600 patients were treated. If it were not for the

work of this hospital, including that done in a ward of King's College Hospital which is temporarily used as an annexe to the Maudsley, the number under treatment in mental hospitals would be appreciably greater.

So far as direct admissions to mental hospitals are concerned, the proportion these bear to the total population of their district varies between 5 and 9 per 10,000, the average for all London being 7 per 10,000. It would be unsafe to take such figures as fully representing the frequency of insanity in the average population, even if the necessary corrections were made for readmissions and age-groups; criteria used in determining the need for mental hospital care vary in different countries and in different parts of the same country. In the admirably detailed report for 1934 of the commissioner of mental diseases in the State of Massachusetts, which has a population about equal to that of London, the rate for all admissions is shown as 15 per 10,000 of population, far higher in cities than in rural districts. It would not however be fair to conclude that there is a much higher incidence of mental disorder in Massachusetts than in London. The same difficulty is found if an attempt is made to compare rate of discharge or duration of treatment with figures published elsewhere. Among the factors affecting the length of detention is the adequacy of social care likely to be available for discharged patients. Psychiatric social workers, trained to deal with such problems, have been employed experimentally at selected mental hospitals of the L.C.C. since 1931; the appointment of a social worker at each of the ten mental hospitals has now been authorised, in addition to the five who work at the Maudsley Hospital.

MENTAL DEFICIENCY

It is in regard to mental defect that social treatment is most conspicuous in the report. Systematic supervision of defectives in their own homes has been carried out in more than 3000 cases; a third of these are engaged in remunerative work. The Council also maintains fourteen occupation and

¹L.C.C. Annual Report of the Council, 1934. Vol. VI. Mental Hospitals and Mental Deficiency. Pp. 64. 1s.

craft centres for the training of defective patients outside any institution, while for the 6000 cared for in hospitals and homes there is educational provision and employment, the extent of which may be recognised from the financial appendices to the report.

RESEARCH

The recognition by the Council of the necessity for more than the routine care of the mentally ill, exacting and primary though it be, is strikingly seen in the passages dealing with research and teaching. The Council is responsible for the maintenance of the only university psychiatric clinic in England; as a centre of post-graduate teaching in this branch of medicine, the Maudsley Hospital occupies a place and influence comparable to that of the Henry Phipps Clinic in the United States. The research carried out there, in the wards and the central pathological laboratory, could hardly have been so active and fruitful if the Council had not shown an enlightened concern for these less obvious obligations. Throughout the mental hospitals, as may be seen from one of the appendices, investigation is pursued into the manifold problems of mental illness along varied and profitable lines. Such evidence disposes of the notion that in mental hospitals lethargy is the doctors' portion, as well as the patients'.

CLEAN WATER PROBLEMS

THE Water Pollution Research Board, in addition to its exhaustive survey of the River Tees summarised in a previous issue (1935, ii., 1322), has engaged in many other activities during the past year. These are briefly described in the annual report, in which is included the report of the director of research, Mr. H. T. Calvert, Ph.D.¹

The work on base-exchange methods of water softening has been continued and materials have been obtained from clays found in Britain which are equal in softening properties to some of the imported materials used for this purpose and are more resistant to disintegration. Experiments with synthetic resins prepared at the Teddington laboratory have shown that some of these possess marked base-exchange properties. Other synthetic resins prepared from aromatic bases such as aniline will remove not cations but anions, so that by the combined use of the two classes the solids in Teddington (equals London) tap water can be reduced from about 33 to 1 part per 100,000, while the same process carried out two or three times will remove most of the salt from sea water. This fact may be of the greatest importance to seamen who, like Bligh of *Bounty* fame, are forced to make voyages in open boats or other small craft where storage for water is so limited that sea water must be distilled, a process which requires not only a still but a supply of fuel to be carried. If Prof. G. T. Morgan and his colleagues can render untrue the words of the Ancient Mariner: "Water, water, everywhere, nor any drop to drink," they will deserve well of all seafaring men.

Work on the activated sludge process of sewage purification goes on under Prof. Topley at the London School of Hygiene. Sludges suited for treatment of special impurities in liquids have been prepared. The effect of bubbling various gases through sewage, directed by Prof. F. G. Donnan at University College,

seems to indicate that the production by this means of thin layers, almost all surface, causes a separation of colloidal matter, whilst simple stirring has some effect in this direction. We know of cases where this action is being tried for improvement of sedimentation. It is, after all, a common laboratory practice to stir a liquid in which a precipitate has been produced, in order to render the separated substance coarser grained and easier to filter.

The officers of the Board do not rely only on the printed word to make the present state of knowledge of water purification known to interested persons. We have before us a summary of a lecture given by the assistant director, Mr. A. Parker, D.Sc., to the Bristol branch of the Society of Chemical Industry. The effluent from a beet-sugar factory of average size (3 or 4 million gallons a day) would, said Dr. Parker, have about the same polluting action on a stream as the sewage of a city of the size of Bristol, and the waste waters of all the factories in this country would be roughly equivalent to the domestic sewage of London. This shows the magnitude of the pollution from a relatively new industry, and explains the many rivers which have been temporarily ruined by it. Investigations completed by the Board have shown that after simple preliminary treatment the waste waters from such works can be used again in the factory processes, leaving little or no effluent for disposal. What effluent there is can be effectively purified before discharge by biological oxidation in percolating filters. Similarly the effluent from dairies and milk products factories in Britain, amounting in wash waters alone to the equivalent of the sewage from a population of 400,000, can be satisfactorily purified by oxidation, assuming that the whey, skim milk, and buttermilk are not run to waste. The story of river pollution is, said Dr. Parker, one of unbalanced development of industry in districts not already industrialised. In many cases the knowledge of purifying processes was available to render the effluents harmless and to prevent not only the disfigurement of our watercourses but the rendering useless of the water for other industries down stream. The methods whereby the discharge of sewage can be rendered harmless cost money, but it is money well spent, and it may be hoped that by systematic research the cost may be reduced.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
JAN. 25TH, 1936

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2505; diphtheria, 1356; enteric fever, 19; acute pneumonia (primary or influenza), 1376; puerperal fever, 47; puerperal pyrexia, 92; cerebro-spinal fever, 21; acute poliomyelitis, 9; acute polio-encephalitis, 1; encephalitis lethargica, 9; dysentery, 33; ophthalmia neonatorum, 70. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Jan. 31st was 4111, which included: Scarlet fever, 1108; diphtheria, 1081; measles, 578; whooping-cough, 653; puerperal fever, 22 mothers (plus 16 babies); encephalitis lethargica, 282; poliomyelitis, 4. At St. Margaret's Hospital there were 23 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 57 (7) from measles, 7 (1) from scarlet fever, 33 (10) from whooping-cough, 45 (5) from diphtheria, 42 (16) from enteritis under two years, and 104 (20)

OBITUARY

SIR JOHN MARNOCH, K.C.V.O., M.B. Aberd.
HONORARY SURGEON, H.M. HOUSEHOLD IN SCOTLAND

THE death occurred on Sunday last in Aberdeen, in his sixty-ninth year, of the well-known surgeon Sir John Marnoch, emeritus regius professor of surgery in the University of Aberdeen.

John Marnoch was the son of the late James Marnock of Aberdeen, where he was born in 1867. He was educated at his native grammar school and

SIR JOHN MARNOCH

[Photograph by Elliott & Fry

university (King's and the Marischal College), and graduated as M.B., C.M.Aberd. in 1891 with the highest honours, having previously taken the M.A. degree. He acted as house physician and house surgeon at the Aberdeen Royal Infirmary, and held similar posts at the Aberdeen Hospital for Sick Children, and was marked out for promotion by being appointed assistant to the professor of physiology in the university. He was elected assistant

surgeon to the Royal Infirmary, promoted quickly as full surgeon, and filled the post of lecturer on clinical surgery at the infirmary. In 1909 he became regius professor of surgery in the university, a position which he held at the outbreak of war. During the war he was in charge of the section of special surgery, 1st Scottish General Hospital, with the rank of brevet-colonel, A.M.S., and in 1915 received the C.V.O. At different times he held local public appointments as medical officer of the Shipmasters' Society and the Gas Corporation, and as secretary of the Medico-Chirurgical Society of Aberdeen, and was also medical assessor of the district under the Workmen's Compensation Act.

From a man, with such medical and multifarious public duties no large literary output could be expected, but Marnoch's earlier contributions to medical literature ranged over a large area, contributions from his pen appearing on various clinical subjects in the *Journal of Anatomy and Physiology*,

in the *Scottish Medical and Surgical Journal*, in the *Annals of Surgery*, in the *British Journal of Surgery*, the *British Medical Journal*, and *The Lancet*. A paper in the *British Medical Journal* in 1909 on treatment of gastric ulcer gave a useful account of the complications and sequelæ as then understood attendant on the treatment of gastric ulcer, while a paper in THE LANCET, published shortly before, formed a practical contribution to the pathogenesis of cancer. The two essays show how thoroughly well and practically informed Marnoch was. He was appointed examiner in surgery at different times in the universities of Edinburgh and Durham, and was a fellow of the Association of Surgeons of Great Britain and Ireland. He was appointed surgeon to His Majesty's Household in Scotland, and a D.L. for his county. In 1928 he was created K.C.V.O., while in 1932, when his position of regius professor of surgery terminated, he was appointed emeritus professor and received the distinction of LL.D. Aberd.

Prof. J. R. Learmonth writes: "It was my misfortune that I did not meet Sir John Marnoch until after his retirement from active surgical practice; yet so profound an impression had he made on professional life in the north of Scotland, and so frequent are references to his judgment and skill, that it is difficult to think of him as other than still in his hey-day.

"For the first eight years of his professional career, Marnoch carried on a general as well as a surgical practice. This experience was reflected throughout his whole life, for it enabled him to understand the social and economic factors that may influence treatment, and his advice was always tempered by an appreciation of these. He could and did understand the difficulties under which practitioners may have to work, and throughout his long and busy life he was ready to help them in these difficulties, irrespective of any financial return for his services. In 1900 he was elected as full surgeon to the Aberdeen Royal Infirmary, and remained in charge of wards for the long period of 32 years. This period saw rapid advances in the possibilities and applications of surgery, and of these he took full advantage. Early in his career, therefore, he acquired an exceedingly large clinical experience. This he constantly tempered by the exercise of his own judgment; and it is to be noted that he brought to this task intellectual qualities of the first order, which his academic record as a student had promised. In consequence, he soon acquired the power of making rapid judgments, and the almost invariable correctness of these has been traditional. To this power he added operative dexterity that was frequently uncanny. He was never obviously in haste, nor was his extraordinary rapidity of a spectacular type. It was part of the man himself: a ruthless shedding of all but the essential steps, and a minimum of movement in accomplishing these. At the end of each operation he had done his best.

"During the years of the war the combination of his military and civil duties, and lack of assistance, laid upon him a burden that must have been well-nigh intolerable. He never enjoyed really robust health; yet the work he overtook so uncomplainingly would have proved too much for many a stronger man. There is no doubt that the incessant toil of these years contributed to his final illness. As a teacher he was essentially eclectic. He taught

(Continued from previous page)

from influenza. The figures in parentheses are those for London itself.

The mortality from influenza is maintained, the total deaths for the last eight weeks (working backwards) being 104, 89, 110, 110, 80, 67, 62, 45. The deaths this week are scattered over 48 great towns, Manchester reporting 8, Birmingham 7, Leeds 5, Liverpool 4, Bolton 3, no other great town more than 2. Liverpool had to report 13 deaths from measles, Manchester 8, Birkenhead and Warrington each 4, Croydon and Salford each 3, Birmingham had 4 deaths from whooping-cough, Birkenhead 3. Deaths from diphtheria were reported from 35 great towns; 3 from Bury, no other great town more than 2.

The number of stillbirths notified during the week was 260 (corresponding to a rate of 41 per 1000 total births), including 31 in London.

fundamentals, and that dogmatically. His aim was to equip his students with a sound elementary framework on which they might build; and no one was better able than Marnoch to select what was needed for the general practitioner; he knew from experience. The same principle of reduction to fundamentals coloured his whole outlook upon the art and craft of surgery; and it is well that there be those who can assess so broadly. Only three weeks ago, alas, I asked him what knowledge had been of greatest service to him in his crowded life. Without hesitation (and Sir John never hesitated, wherein lay his strength) he replied: 'A knowledge of inflammation, its results and its treatment.' This might well become a motto for surgical class-rooms, in an era when students are apt to be enamoured of intricate procedures. Those who knew him will remember well the click of the tongue with which he commented upon, and so surely relegated to their proper place, the 'ingenious' operations that still find their way into surgical literature. To speak colloquially, what he taught, stuck; and it could not escape the notice of a newcomer to the district, that practitioners trained by him constantly made the comment: 'Sir John used to say.'

"It was characteristic of Marnoch that his pleasures and hobbies were simple, and once chosen remained his life-long solaces. He was a skilled violinist, and for many years delighted in weekly quartettes in which his fellow players were invariably the same. As an alternative, he delighted in Highland music, and it is sad to know that his illness separated him from his violin during the years of his retirement. His sport was salmon-fishing, and this he was able to follow until the summer of 1935, when to his great delight he was able to land the biggest fish caught that year in the Spey. In his friendships his early loyalties were lifelong, and ended only by death. His allegiance, once given, was enduring, and carried with it the invaluable attribute of unbiased comment and criticism; of this I speak with gratitude, for frequently I turned to him as one who would give me wise and penetrating advice; and I never turned to him in vain.

"Marnoch's whole life was determined by his intellectual honesty. He was honest in his surgery; honest in his appraisal of it; honest in his dealings with his colleagues; and honest in his dealings with his fellow-men. He would have despised a panegyric as an obituary notice; his view was that he had given due consideration to his duties, and had then carried them out to the best of his ability. How well he succeeded, a generation of students of Aberdeen can testify."

Sir John Marnoch married in 1900 Agnes Holt, daughter of the late Alexander Macdonald, of Garmouth, whose devoted care did so much to lessen the bitterness of physical incapacity during the later phases of his illness. Of their two daughters, the elder is married to a biologist in Melbourne, the younger is the wife of a physician in Toronto.

JOSEPH WILLIAM ROB, O.B.E., M.D. Camb.

Joseph William Rob, who died in London on Feb. 1st, was born at Skipton-on-Swale in 1876, the son of Mr. J. D. Rob, and received his education at St. John's College, Cambridge, where he was a scholar and graduated as B.A. in 1898 with first-class honours in the Natural Sciences Tripos. He proceeded to St. Thomas's Hospital, where he served as house surgeon and graduated M.B., B.Chir. Camb. in 1902, later

proceeding to the M.D. degree. He practised for a time in Thirsk and later at Weybridge, and was medical officer at the Walton-on-Thames Cottage Hospital and the Masonic Institution for Girls. He contributed interesting clinical papers to THE LANCET in 1906 and 1908, and earned a sound reputation as a practitioner.

AMY SHEPPARD, O.B.E., M.B. Lond., D.P.H.

Dr. Amy Sheppard, consulting ophthalmic surgeon to the Elizabeth Garrett Anderson Hospital, died on Jan. 22nd in her 77th year after an illness which had lasted a few months.

The daughter of Thomas Sheppard of Kingswood, near Birmingham, Amy Sheppard was born at Dudley, Worcestershire. She was educated at a private school in Stourbridge, and before taking up medicine, which was at that time still an unusual career for a woman, she studied science at Mason College, Birmingham, now incorporated in the University of Birmingham, whence she matriculated in 1884. She then went to University College, London, and passed the preliminary science examination in 1885 before entering the London (R.F.H.) School of Medicine for Women in October of the same year. She qualified M.B. Lond. in 1892 and decided soon after to specialise in ophthalmology, becoming clinical assistant at the Royal London Ophthalmic Hospital and she continued this work for many years.

In January, 1895, she was appointed assistant physician to the Elizabeth Garrett Anderson Hospital (then the New Hospital), but only held this appointment for a few months, resigning it in the following April to become assistant ophthalmic surgeon to the hospital. In 1898, for no other reason than to prepare herself to give a short course of lectures on public health, Dr. Sheppard took the D.P.H. Camb.; though this diploma had been established more than 20 years before she was one of the first two women to take it, the other being the late Dr. Helen Bittell. In 1906 she succeeded Miss Charlotte Ellaby as ophthalmic surgeon to the Elizabeth Garrett Anderson Hospital, a post which she held for 16 years. Dr. Sheppard was also ophthalmic surgeon to the Medical Mission Hospital at Canning Town and medical examiner to the Girls' Public Day School Trust. By the time the late war started Dr. Sheppard was thus well established in her specialty and when the Military Hospital, Endell-street, run entirely by medical women, was established she accepted the invitation to join its staff in the capacity of ophthalmic surgeon. She also acted as ophthalmic surgeon to the Q.M.A.A.C. at Isleworth, and for these services she was made an O.B.E. in 1919. Dr. Sheppard continued her private consulting practice

DR. AMY SHEPPARD

[Photograph by Elliott & Fry]

proceeding to the M.D. degree. He practised for a time in Thirsk and later at Weybridge, and was medical officer at the Walton-on-Thames Cottage Hospital and the Masonic Institution for Girls. He contributed interesting clinical papers to THE LANCET in 1906 and 1908, and earned a sound reputation as a practitioner.

until the late spring of last year when the state of her health caused her to live more and more at the country cottage near Limpsfield which had already been a week-end resort for many years.

Dr. Sheppard might be called one of the pioneer medical women, since she was only No. 140 on the register of the London School of Medicine for Women. She took the greatest interest in the development of opportunities for women in professional and other work. Though she never joined the militant section of the suffragettes she had sympathy with their activities and lost no opportunity of explaining the need for militant tactics to those who were sceptical. She was prominent among those who made a principle of resisting taxation because they had no vote, and as a result more than once her possessions were sold up. Early in her career Dr. Sheppard paid a special visit to India to study cataract operation by the method of "Jullundur" Smith, and on her return recorded her impressions of this technique in a contribution to the *British Medical Journal*. She was a prominent member of the London Association of the Women's Medical Federation, and when she lived chiefly in London regularly attended its meetings. She was always alert to notice new members or visitors and to put them at their ease with a friendly word. Her rather diffident manner concealed decided opinions and she won the respect of her colleagues on the council of the Association by her pertinacity in sticking to her views on important points of principle, though she was always ready to defer to the opinion of others when no great matter was at stake.

Dr. Sheppard was an expert and very clever gardener with a special interest in the culture of lilies. She had a large circle of acquaintances but few close friends; there was something elusive about her which perhaps added to her charm. She will be greatly missed at the gatherings of the London Association and at the larger parties when members of the council of the Medical Women's Federation are entertained.

**GILBERT EDWARD BROOKE, L.R.C.P. & S.,
D.P.H. Edin.**

NEWS has reached this country from Singapore of the death of Dr. Gilbert Edward Brooke, formerly chief health officer of the Straits Settlements. The son of the late Capt. E. F. B. Brooke, he was born at Hyères in 1873 and educated at Monkton Combe School, Bath, and at the Ouchy School, Switzerland, whence he proceeded to Pembroke College, Cambridge. He graduated at Cambridge as B.A. in 1894, did not pursue the medical curriculum, but continued his studies at the London Hospital, where he was a prominent footballer. He took the triple Scottish qualification in 1897 and later the diploma of D.P.H., and after brief service in the mercantile marine, became Government medical officer to the East Harbour, Turk's Island, West Indies. He was appointed medical officer of health to the Caicos Islands, while at the time of the war he had been port health officer at Singapore for some years, later becoming chief health officer of the Straits Settlements. At Singapore he was lecturer on hygiene to the medical school, acted as examiner in chemistry and physics, and wrote several small text-books on hygiene, parasitology, and sanitary science from the tropical point of view.

In 1920 there appeared from Brooke's pen a well-written "Manual for Ships' Surgeons and Port Health Officers," in which he informed the ship's

surgeon what the sanitary authorities of the port will want from him in the matter of returns, how he can help them most effectively, and how as a consequence he can secure for his ship the shortest delay at quarantine. The double aim of the book was to prevent dangerous conditions from eluding medical observation and to abbreviate periods of detention of the ship that must hamper trade, and the advice was succinct and practical. In the same year there appeared a new and enlarged edition of a work on "Medico-tropical Practice," which had been written some twelve years before and whose favourable reception justified reissue. A communication from him to THE LANCET of March 14th, 1931, set out fully the importance which he considered should be attached to the bills of health carried by sea-going ships, and regretting certain movements made for their abolition. The Far Eastern Health Bureau in connexion with the health organisation of the League of Nations came into existence in 1925 when Brooke was appointed director. His organising work in the collation and distribution of information as to the prevalence of epidemic disease was recognised as of the first value, for the bureau was placed by him in a position to collect regular information from a large number of ports. Similar capacity for strenuous work on organised lines was displayed by him in the construction in Sarawak of a health service; on this he was engaged until the time of his death.

Gilbert Brooke by both his practical labours and literary output, which was large and varied, won for himself a high position in the Colonial Medical Service.

WILLIAM CRAN DUTHIE, M.B. Aberd.

THE death occurred in Blackburn Royal Infirmary on Jan. 24th of Dr. Cran Duthie; he died in the institution with which he was long and valuably associated. The son of the Rev. George Duthie, he was born at Kinkell, Perthshire, in 1871, and was educated at Aberdeen University where he graduated M.B., C.M. in 1893. In the following year he started practice in Blackburn and later was appointed assistant surgeon to the Blackburn Infirmary. He was for 15 years, until his retirement in 1931, a member of the staff where he was popular alike with colleagues and patients, and unanimous expressions of gratitude for his services were expressed by the board on his retirement. Dr. Duthie is survived by a widow and a large family, four of whom are connected with the medical profession, two as doctors—Dr. Lister Duthie being in practice with him—one daughter as a nurse, and another daughter as a radiographer.

**HENRY BULLEN BEATTY, L.R.C.P. & S.I.
SURGEON-CAPTAIN R.N., RETIRED**

Surgeon-Captain Henry Bullen Beatty, who died on Jan. 21st, 1936, at his residence, in Rathmines, aged 75, was born in Dublin, and educated at Wesley College and at the Carmichael Medical School in that city. He obtained the conjoint qualifications of Ireland in 1884, and joined the medical service of the Royal Navy, where he saw much foreign service, first on the west coast of Africa, and later in the South Seas and on the Australian station. In 1904 he was appointed to the Royal yacht, H.M.S. *Osborne*, and after that appointment, from 1908 to 1911, he was surgeon to the Marines at Chatham. Subsequently he served again on the Australian station, and was due to retire in 1914, but owing to the outbreak of the war he was retained in the service until 1917. He returned to Dublin in broken health, but

was able a year later to assist in establishing the earliest Pensions Boards in Dublin. For several years he was engaged in pensions work, acting as chairman of boards, a work for which he was specially fitted by his quick grasp, his knowledge of regulations of procedure, and his judicial mind. Those who worked with him found him a very fair, efficient, and pleasant chairman. During the last five years his health failed badly, and he was rarely able to leave the house, but his interest in world and domestic affairs was unimpaired.

ARCHIBALD ALEXANDER GEORGE DICKEY,
M.B.E., M.D. R.U.I.

Dr. Archibald Dickey, who died on Jan. 19th at the age of 74, was a well-known physician in Colne

and later in Bolton. He was for 33 years in practice at the former centre and for 15 years at the latter, only leaving on his retirement a few months ago. He received his medical education at Queen's College, Belfast, was a scholar and prizeman, took the double Irish diploma, and in 1883 graduated as M.D. R.U.I. At Colne he was in charge of the Military Hospital during the war and was awarded the M.B.E. He was a justice of the peace for the borough, surgeon to the Post Office and the St. John Ambulance Brigade, and honorary medical officer to the Cottage Hospital. When in 1921 he left Colne to practise in Bolton, he held various public appointments and continued his interest in the work of the St. John Ambulance Brigade. He died at the residence, in Pwllheli, of his son, Dr. H. W. Dickey.

MEDICAL NEWS

University of Cambridge

Dr. Samuel Nevin has been appointed to the Pinsent-Darwin studentship for the study of mental pathology. He has lately held a Halley Stewart research fellowship at the National Hospital, Queen-square.

University of London

Prof. H. H. Woollard has been appointed as from Oct. 1st, 1936, to the university chair of anatomy tenable at University College. Since 1929 he has been professor of anatomy at St. Bartholomew's Hospital medical college, having previously held the chair of anatomy at Adelaide University.

The title of reader in pharmacological chemistry in the University has been conferred on Mr. H. R. Ing, D.Phil., in respect of the post held by him at University College.

Dr. Ing was born in 1899, and was educated at Oxford High School and at New College, Oxford, where he graduated as M.A. in 1921 and D.Phil. in 1924. From 1923 to 1925 he was a university demonstrator in organic chemistry at Oxford, after which he went to Manchester with a Ramsay memorial fellowship. In the following year he became research chemist for the Manchester cancer committee, and in 1928 he came to London to take up his present post as lecturer in pharmacological chemistry at University College.

The William Julius Mickle fellowship for 1936 has been awarded to Dr. H. P. Himsforth, deputy director of the medical unit at University College Hospital medical school.

Owing to the illness of Dr. H. M. Traquair, the lectures on Perimetry, which were to have been given at University College Hospital medical school on Feb. 10th and 11th, have been postponed.

Royal College of Physicians of London

At a meeting of the College held on Jan. 30th, with Lord Dawson of Penn, the president, in the chair, it was announced that the Gilbert Blane gold medals for 1935 had been awarded to Surgeon Lieutenant Commander A. A. Pomfret and Surgeon Lieutenant Commander W. G. Fitzpatrick. Dr. Rupert Waterhouse was appointed a representative on the medical advisory committee of the British Health Resorts Association. The Harveian librarian announced the presentation by Prof. Roy Dobbin of a sumptuously bound copy of the manuscript of Ibn Al-Naphis, which dates from the thirteenth century, and in which is the first-known description of the Mechanism of the Lesser Circulation.

Dr. E. L. Middleton will deliver the Milroy lectures on industrial pulmonary disease due to the inhalation of dust, with special reference to silicosis, on Feb. 27th and March 3rd; Dr. R. A. McCance the Goulstonian lectures on medical problems in mineral metabolism on March 5th, 10th, and 12th; Dr. John Parkinson the Lumleian lectures on enlargement of the heart on March 17th and 19th; and Mr. Joseph Needham, Sc.D., the Oliver-Sharpey lectures on chemical aspects of morphogenetic determination on March 24th and 26th.

The following candidates, having satisfied the censors' board, were admitted members of the College:—

Felix Wilfrid Arden, M.D. Adelaide; Sailendra Mohon Basu, M.B. Rangoon; James Frederick Brailsford, M.D. Birm.;

Geoffrey Oswald, Atyeo Briggs, M.B. Camb.; Francis Hayling Coleman, M.B. Camb.; Leybourne Stanley Patrick Davidson, M.D. Edin.; Richard Heyworth Dobbs, M.B. Camb.; Colin Campbell Edwards, M.B. Sydney; David Stanley Fairweather, M.B. Edin.; David George Ferriman, M.B. Oxon.; Alan Morton Gill, M.D. Lond.; Arthur Rupert Hallam, M.D. Edin.; Ernest Arthur Hardy, M.B. Lond.; Herbert Edward Holland, M.B. Sheff.; Philip William Hutton, M.B. Camb.; Alan Leon Jacobs, M.B. Oxon.; Evan Idris Jones, M.B. Lond.; Francis Avery Jones, M.B. Lond.; Edwin James Reid Leiper, M.B. Aberd.; Jack Watson Litchfield, M.B. Oxon.; Leo McGoldrick, M.B.N.U. Irel.; Wilfrid Marshall, M.D. Aberd.; James Lister Newman, M.D. Camb.; John William Osborne, M.B. Sydney; John Scholes Parkinson, M.B. Manch.; Abdel Aziz Sami, M.B. Cairo; Alice Mary Stewart, M.B. Camb.; Charles Henry Stewart-Hess, M.B. Liverpool; Harold Midgley Turner, M.D. Manch.; and Rustom Jal Vakil, M.B. Lond.

Licences to practise were granted to 140 candidates (132 men and 8 women) who have passed the final examination of the Conjoint Board. The following are the names and medical schools of the successful candidates:—

A. W. Abramson, Camb. and St. Thomas's; Ruth M. Addison, Roy. Free; G. W. Alderman, London and Leeds; Sivasithamparam Balasingam, King's Coll.; E. J. W. Barnard, St. Bart.'s; H. F. Barnard, Westminster; A. B. Baxter, Guy's; David Bobker, Charing Cross; E. S. Bompas, St. Thomas's; A. W. Bone, Camb. and London; J. C. B. Bone, Middlesex; R. E. Bonham-Carter, Camb. and St. Thomas's; J. P. Brazil, St. Mary's; B. B. Bridges, Guy's; D. H. D. Burbridge, Middlesex; J. C. Busby, Camb. and St. Mary's; L. S. Calvert, Leeds; Josephine H. Campbell, King's Coll.; W. W. Cashmore, Guy's and Birm.; S. R. Chandra, Calcutta; E. P. Clarke, St. Bart.'s; J. H. Coles, King's Coll.; Kathleen Craddock, Roy. Free; Montague Curwen, Middlesex; C. S. Darke, Guy's; J. E. A. David, Camb. and St. Bart.'s; J. R. Davidson and H. J. Davies, Univ. Coll.; J. N. Deakin, Birm.; G. G. Doel, King's Coll.; B. J. Doran, Guy's; C. A. Dowling, Camb. and King's Coll.; H. G. Earnshaw and R. B. Evans, London; F. I. Firth, Manch.; Robert Fleming, Geneva and London; C. B. Franklin, St. Bart.'s; D. F. Freebody, Guy's; J. E. Garson, Madras and West London; Joyce M. George, King's Coll.; Jaharlal Ghosh, Calcutta and St. Bart.'s; D. R. Gibson, St. Mary's; Sholem Glaser, Cape and London; Louis Greenbaum, London; J. C. Harland, Westminster; H. R. S. Harley, Guy's; G. D. Harthan and John Heginbotham, Manchester; A. G. Hemsley, Middlesex; G. H. M. Hemsted, St. Mary's; R. K. R. Henry, A. G. W. Hill, and B. W. Hunt, Guy's; C. W. Hutt, Camb. and St. Bart.'s; W. G. Hutton, Camb. and Leeds; Mohammed Inayatullah, Agra and Manch.; Meir Irving, Charing Cross; Gwyneth M. Jenkyn-Owen, Roy. Free and West London; A. C. Jones, Middlesex; S. E. L. Kahla, Sydney and London; Ernest Kaplan and H. M. Kelsey, Guy's; K. C. Kershaw, Manch.; F. B. Kierander, St. Thomas's; W. J. Latham, London; L. R. Leask, St. Bart.'s; H. A. Leggett, Guy's; Maurice Lewis, Univ. Coll.; R. N. A. Leyton, Camb. and Westminster; Milton Lipson, Charing Cross; S. E. Littlepage, Manch. and St. Bart.'s; J. M. Lockett, St. Bart.'s; R. D. McDonald, Cape and London; J. T. Mair, Westminster; C. W. Maisey, St. Thomas's; Simon Marinker, Middlesex; H. A. C. Mason, St. Thomas's; Leslie Merrill, Guy's; P. J. W. Mills, St. Bart.'s; A. G. Moore, St. Thomas's; F. T. Moore, St. Bart.'s; Margaret J. Moore, Roy. Free; F. L. E. Musgrave, Guy's; R. O. G. Norman, Camb. and London; J. D. Ogilvie and W. A. Oliver, St. Bart.'s; W. V. Owen, Camb. and Westminster; D. E. Parry, St. Mary's; J. C. Patel, Bombay; N. O. Paterson, Guy's; E. N. Pearlman, Middlesex; John Pemberton, Univ. Coll.; R. R. Prewer, St. Bart.'s; D. E. Price, St. Mary's; Joseph Rabinovitch, Leeds; O. N. Ransford and H. W. Rees, Middlesex; J. L. Reid, Oxon. and Middlesex; Guy Rigby-Jones, Camb. and St. Thomas's; Barnard Robbins, King's College; A. N. Roy, St. Bart.'s; P. S. Sambandam, Madras and West London; L. J. Sandell, St. Bart.'s; H. V. Sankararaya, Mysore and London; Eric Sayle, Guy's; Morris Schwartz, Univ. Coll.; Rupert Solley, Camb. and London; G. C. Steel, Middlesex; D. E. Stephens, Cape and St. Mary's; B. P. Stone, Camb. and King's Coll.; J. S. Stuart, Guy's; F. J. E. Stuhl, Camb. and Westminster; K. H. Sugden,

St. Bart.'s; C. H. Tanner, Cardiff; B. W. Thomas, Univ. Coll.; Dorothy J. Thompson, Camb. and Bristol; T. H. Tidswell, St. Bart.'s; R. C. Tudway, Univ. Coll.; R. G. Tuke, St. Thomas's; J. E. Underwood, St. Bart.'s; G. J. van der Merwe, Cape and Guy's; C. W. H. Van der Post and W. M. Van Essen, Guy's; G. L. Wainganker, Manch. and West London; G. W. Ward, Manch.; J. H. Ward, Camb. and St. Bart.'s; A. G. Waters, Cardiff and London; S. A. Way, Middlesex; Samuel Weinstock, London; J. L. Whately, Birm.; R. R. Willcox, St. Mary's; E. G. Williamson, Camb. and Birm.; Louise F. Wilson, Yale and West London; Anthony Winder, Camb. and London; H. L. Wolfe, St. Bart.'s; L. A. C. Wood, Camb. and St. Thomas's; J. E. Wooding, Camb. and St. Bart.'s; G. N. Wright, Guy's; P. L. Young and W. J. Young, St. Bart.'s.

Diplomas were granted jointly with the Royal College of Surgeons to the following candidates:—

Diploma in Public Health.—S. D. Elliott, R. J. Farnbach, R. A. Jones, G. G. Kayne, W. F. Lane, Catherine E. Murray, C. R. Naidu, and T. S. Rodgers.

Diploma in Psychological Medicine.—J. L. Rates, A. J. Galbraith, J. F. Galloway, S. L. Last, S. A. Mackeith, W. H. McMenemy, K. R. Masani, J. A. Smeal, Alfred Torrie, Rosalind Vacher, and J. H. Watkin.

Diploma in Laryngology and Otolaryngology.—B. T. Bernstein, G. B. Ludlam, R. F. J. Martin, Narayana Srinivasan, T. G. Swinburne, and W. E. Williams.

Diploma in Tropical Medicine and Hygiene.—W. K. Cheng, Anastasio D'Souza, J. S. Gibson, Kalidas Mitra, and V. T. Vagh.

Diploma in Medical Radiology.—E. W. Casey and Frank Ellis.

Diploma in Anaesthetics.—Olive M. Anderson, H. B. Logan, S. D. McAusland, G. R. Phillips, K. B. Pinson, Benjamin Weinbren, H. L. Willey, and C. H. Wilson.

Society of Apothecaries of London

At recent examinations the following candidates were successful:—

Surgery.—R. H. Bembridge, King's Coll. Hosp.; H. A. Koretz, Univ. of Manch.; and G. N. Rodgers, Bombay and West London Hosp.

Medicine.—F. E. Bedell, St. Mary's Hosp.; M. G. H. Jones, Welsh National School of Medicine; and R. L. Walmsley, Univs. of Camb. and Leeds.

Forensic Medicine.—F. E. Bedell, St. Mary's Hosp.; N. Bickford, Middlesex Hosp.; E. E. Evans, Guy's Hosp. and St. George's Hosp.; M. G. H. Jones, Welsh National School of Medicine; and R. L. Walmsley, Univs. of Camb. and Leeds.

Midwifery.—J. D. Anderson, St. Bart.'s Hosp.; G. B. Barbour, Univ. of Camb. and Guy's Hosp.; E. E. Evans, Guy's Hosp. and St. George's Hosp.; E. M. Frankel, Westminster Hosp.; D. L. Jones, Univ. of Liverp.; J. P. McGuire, Calcutta and St. Mary's Hosp.; I. M. Monare, Royal Colleges, Edin.; and C. J. S. Sergel, Univ. of Camb. and St. Mary's Hosp.

The following candidates, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery: G. B. Barbour, R. H. Bembridge, J. P. McGuire, G. N. Rodgers, and R. L. Walmsley.

Scottish Conjoint Board

At recent examinations by the board of the Royal Colleges of Physicians and Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow, the following candidates were successful:—

Eric Greenhalgh, O. S. Sela, Vartheanather Nadarajah, O. W. Marienfeld, N. S. Mohammed, F. H. Wilson, P. C. Burgess, J. H. Lichtenbelt, Harold Jacobs, Edith H. Busse, D. A. S. Martin, L. L. Harrop, Fritz Buchsbaum, Alfred Rosenbaum, Mollereus Couperus, F. J. Beaton, Irving Dolsky, Alexander Crawford, Viktor Klare, R. M. Boveri, H. I. Russek, A. J. Snyder, N. R. Janes, O. K. Kballaf, K. G. Naidoo, Mirajud Din, Emma Pines, Harry Friedman, S. H. Fuchs, K. T. Bluth, Sophia V. Elgey, L. O. Adesigbin, S. F. Auerbach, K. M. El-Moshneb, and W. W. Weir.

Pharmaceutical Society of Great Britain

A meeting of this society will be held at 17, Bloomsbury-square, London, W.C., on Tuesday, Feb. 11th, at 8.30 p.m., when Prof. E. C. Dodds will give a lecture on chemical and pharmacological aspects of the hormones.

Presentations to Medical Men

Kelso.—Dr. A. D. Fleming, who is retiring after 45 years' medical practice, has received a standard lamp from the people of the burgh in recognition of his services to them. *Aboyne.*—A cheque has been presented to Dr. W. Brodie Brown who, after 35 years' practice in the district, has been succeeded by his son. *Hove.*—Dr. H. C. Upton has been given an illuminated address in commemoration of 44 years' service on the governing body of the town, for 27 of which he has been an alderman. He is now 90 years of age. *Uxbridge.*—At the Uxbridge and District Cottage Hospital Dr. George Black was recently presented with a cheque from his colleagues and friends. Dr. Black, who has been in practice in the town for 15 years, is retiring to Hurstpierpoint.

New Hospital for Basingstoke

A good site has been secured for the erection of a new hospital at Basingstoke for which £1800 has been paid.

Hunterian Society

On Monday, Feb. 24th, Sir Lenthal Cheatele will deliver the Hunterian oration of this society at the Mansion House, London, E.C., at 9 p.m. He will speak on John Hunter's Time and Ours. The annual dinner of the society has been cancelled.

Milk for Juvenile Workers

Messrs. Peek Frean and Co. are offering their juvenile workers, some hundreds in number, a one-third-pint bottle of milk at $\frac{1}{2}$ d. per bottle. On Wednesday afternoon the first bottles under this scheme were handed to the workers by the chairman of the Milk Marketing Board.

Developments at Bath

A method is in future to be used at Bath by which the waters can be atomised for inhalation purposes without lowering their temperature. After sterilisation they are carried through a specially designed electric heater. A new kind of aeration bath is also to be installed, which represents a development of the whirlpool bath and offers the advantages of gentle massage.

National Temperance League

On Friday, Feb. 14th, at 5 p.m., Mr. W. McAdam Eccles, consulting surgeon to St. Bartholomew's Hospital, will deliver the second Rae memorial lecture at the London School of Hygiene and Tropical Medicine, Keppel-street, on Progress and Problems. The chair will be taken by Sir Henry Brackenbury, and Mr. Eccles will illustrate the test for the determination of the actual percentage of alcohol circulating in the blood, especially in relation to road accidents.

New Nurses' Home at Hammersmith Hospital

On Tuesday the London County Council considered spending £104,600 in providing new accommodation for the nursing staff of Hammersmith Hospital. Of the 159 nurses now at work there, 82 occupy the nurses' home and a converted block of the former institution, 17 are housed in the administrative block, 33 in other parts of the hospital, and 27 have to live out. The non-resident nursing staff will be increased to nearly 180 when the new ward block is completed and the former institution reconditioned. The new home, to be completed in the spring of 1938, will be a separate building in the north-west corner of the ample site, six storeys in height, and containing 304 separate bedrooms.

Tuberculosis in Russia

The campaign against tuberculosis in the Soviet Union was discussed at a recent All-Union Conference of Tuberculosis Institutes, which decided on the next steps to be taken. Before the late war, it is stated, there were only about 300 sanatorium beds in Russia, together with some special hospital wards and dispensaries supported by charity. The death-rate from tuberculosis was very high, reaching 33.6 per 1000 in St. Petersburg. To-day there are said to be 500 dispensaries in the All-Russian Republic alone, many of them with day sanatoria; over 26,000 beds are available for adults and children in the sanatoria, and special hospitals for the tuberculous, and more than 27,000 physicians are employed in these institutions. Fourteen provincial institutes and a Central Tuberculosis Institute have been established in the same territory, and each year some 500 doctors take special courses on the treatment of the disease.

Appointments

ADAMS, MARY I., M.B. Belf., D.P.H., has been appointed Assistant Medical Officer for Hammersmith.
 CARTWRIGHT, F. F., M.R.C.S. Eng., D.A., Assistant Anaesthetist at King's College Hospital.
 CRITCHLEY, MACDONALD, M.D. Brist., F.R.C.P. Lond., Neurological Physician to the Royal Masonic Hospital.
 DANCY, NAOMI, M.B. Lond., Assistant Medical Officer for Hammersmith.
 LINDSAY, E. C., M.B. Lond., F.R.C.S. Eng., Surgeon to the Royal Masonic Hospital.

PARLIAMENT

NOTES ON CURRENT TOPICS

Voluntary Hospitals (Paying Patients) Bill

In the House of Lords on Feb. 4th the Voluntary Hospitals (Paying Patients) Bill was considered in Committee.

On the motion of Lord LUKE, several amendments, mainly of a drafting character, were agreed to.

The principal amendment made was in Clause 6, Subsection 3. As printed in the Bill this read: "(3) Except to the extent of an application of funds authorised under subsection (2) of section 3 of this Act, an Order authorising the provision or maintenance of any buildings or beds shall not be construed as conferring on the committee of management any power, which apart from the Order would not be exercisable by them, to apply funds in the provision or maintenance thereof."

On Lord Luke's motion, the following new subsection was inserted: "(3) Except to the extent of an application of funds authorised under subsection (2) of section 3 of this Act an Order shall not be construed as authorising any application of funds."

HOUSE OF COMMONS

TUESDAY, FEB. 4TH

Government and the Distressed Areas

Miss WARD asked the Prime Minister whether he was in a position to make a statement to the House regarding the progress made with plans to deal with the distressed areas.—Mr. E. BROWN, Minister of Labour, replied: Considerable progress has been made by the commissioners in a number of directions in promoting the industrial development and social improvement of the special areas since their last reports were published. Further reports for the six months to Dec. 31st, 1935, are expected shortly, and these, too, will be published in due course.

Unemployed Persons and Insurance Benefits

Mr. DOBBIE asked the Minister of Health whether he was aware that many unemployed persons who became voluntary contributors after Dec. 31st, 1932, and who, owing to their economic conditions, were unable to keep up their contributions, had had to allow their insurance to lapse and were outside the scope of Section 14 of the Act of 1935; and, having regard to the serious hardship of having lost all health insurance and pension benefits, what steps would be taken to give this class the benefit of that section.—Sir K. WOOD replied: The only persons who can be in the position referred to by the hon. Member are those who became voluntary contributors after Dec. 31st, 1932, but paid no contributions in respect of any week subsequent to Dec. 31st, 1933. I have no power to deal with such cases generally by Regulations under Section 14 of the Act of 1935, but if any individual case is brought to my notice I will have it investigated in order to see whether on the facts of that case there is any possibility of securing continuity of insurance.

Unhealthy Basements and Condemned Houses in London

Mr. DAY asked the Minister of Health whether he could state, according to his latest reports, the number of unhealthy basements and condemned houses there were in the County of London; what steps were being taken to deal with the same; and the number of families living more than two and more than three in one room, with separate figures for the borough of Southwark.—Sir K. WOOD replied: According to returns obtained by the London County Council in 1934 there were in London 20,108 underground rooms, including 86 in the borough of Southwark, used for sleeping purposes which were deemed unfit for human habitation within the meaning of Section 18 of the Housing Act, 1925. Action for closing such rooms is proceeding: extended powers for this purpose have been given by the recent Housing Act. As regards the second part of the question, I am not clear

what information the hon. Member desires. The total number of houses scheduled for demolition in the programme submitted by the L.C.C. in 1933 is 33,000. Action with a view to demolition has been initiated in respect of 10,500 houses, including 757 in the borough of Southwark. As to the last part of the question the latest particulars available are contained in Table II. in the 1931 census for the County of London.

Road Accidents in 1935

Mr. McENTEE asked the Minister of Transport the number of persons killed and injured in road accidents during 1935, giving separate figures for pedestrian crossing-places.—Mr. HORE-BELISHA replied: Approximately 6550 persons were killed in road accidents in Great Britain in 1935 as compared with 7343 in 1934. Approximately 219,000 were injured as compared with 231,603 in the previous year. 1935 is thus the first year since the war to show an over-all reduction in casualties. Separate figures for fatalities on pedestrian crossing-places will not be known until the fatal accident returns for 1935 have been received and analysed.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Feb. 11th.

Therapeutics and Pharmacology. 5 P.M. Dr. H. P. Himsforth: Physiological Factors Influencing the Action of Insulin. Mr. H. P. Marks, Dr. Levy Simpson, and Dr. M. W. Goldblatt will also speak.

Psychiatry. 8.30 P.M. Dr. E. T. O. Slater: The Inheritance of Manic-depressive Insanity.

FRIDAY.

Clinical. 5.30 P.M. (Cases at 4.30 P.M.) Dr. T. C. Hunt: 1. Persistent (Edema with Cyanosis, ? Nature.

Ophthalmology. 8.30 P.M. (Cases at 8 P.M.) Mr. John Foster: Vitamins in Ophthalmology. Mr. Arnold Sorsby and Miss L. R. Benham: Allergic Tests in External Eye Conditions.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.

MONDAY, Feb. 10th.—8.30 P.M., Mr. C. S. Lane-Roberts:

Treatment of Sterility.

NORTH-WEST LONDON MEDICAL SOCIETY.

TUESDAY, Feb. 11th.—9 P.M. (The Regal Rooms, Regal Cinema, Finchley-road, N.W.), Dr. J. Russell Reynolds:

Cineradiography.

PADDINGTON MEDICAL SOCIETY.

TUESDAY, Feb. 11th.—9 P.M. (St. Mary's Hospital, W.),

Dr. G. B. M. Heggs: Practical Demonstration on Selected Cases of Skin Disease commonly met with in Practice.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, Feb. 14th.—8.45 P.M. (Miller General Hospital, Greenwich, S.E.), Dr. Geoffrey Bamber: The Treatment of Some Common Affections of the Skin.

SOUTH-WEST LONDON MEDICAL SOCIETY.

WEDNESDAY, Feb. 12th.—9 P.M. (Bolingbroke Hospital, Wandsworth Common, S.W.), Mr. C. D. Read: The Problem of Abortion and Sterilisation.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

THURSDAY, Feb. 13th.—4 P.M. (St. Mary, Islington, Hospital), Dr. W. R. M. Turtle: Clinical Demonstration.

BIOCHEMICAL SOCIETY.

FRIDAY, Feb. 14th.—4 P.M. (London School of Hygiene, Keppel-street, W.C.), Short Communications and Demonstrations.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY.

THURSDAY, Feb. 13th.—8.30 P.M. (11, Chandos-street, W.), Dr. Frank Gray: The Psychopathology of Organic Disease.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

MONDAY, Feb. 10th.—5 P.M., Mr. G. C. Knight: Intestinal Strangulation.

WEDNESDAY.—5 P.M., Mr. G. F. Rowbotham: A Series of Tumours of the Skull. (Hunterian lectures.)

FRIDAY.—4 P.M., Mr. C. H. Fagge: John Hunter to John Hilton. (Hunterian Oration.)

UNIVERSITY OF LONDON.

MONDAY, Feb. 10th.—3 P.M. (London School of Hygiene, Keppel-street, W.C.), Col. L. W. Harrison: Venereal Disease (II.).

WEDNESDAY.—3 P.M. (London School of Hygiene), Col. Harrison: Venereal Disease (III.).

FRIDAY.—11 A.M. (London School of Hygiene), Dr. A. G. Maitland-Jones: Infant Feeding.

- ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.**
MONDAY, Feb. 10th.—5 P.M., Major-General Sir Robert McCarrison: Nutrition and National Health (first of three Lectures).
- HAMPSTEAD GENERAL HOSPITAL, N.W.**
WEDNESDAY, Feb. 12th.—4 P.M., Dr. H. C. Semon: Eczema, Modern Theories and Treatment.
- NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.**
TUESDAY, Feb. 11th.—5.30 P.M., Dr. J. M. H. Campbell: Paroxysmal Tachycardia.
- LONDON SCHOOL OF DERMATOLOGY, 5, Lisle-street, W.C.**
TUESDAY, Feb. 11th.—5 P.M., Dr. H. T. Barron: Common Skin Diseases in Childhood.
WEDNESDAY.—5 P.M., Dr. I. Muende: Histopathology.
THURSDAY.—5 P.M., Dr. J. A. Drake: Some Disorders of Sweating.
- HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.**
WEDNESDAY, Feb. 12th.—2 P.M., Dr. W. G. Wyllie: Pulmonary Fibrosis and Bronchiectasis. 3 P.M. Dr. W. W. Payne: Blood Chemistry in Acute Pulmonary Disorders.
 Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.
- NATIONAL HOSPITAL, Queen-square, W.C.**
MONDAY, Feb. 10th.—3.30 P.M., Dr. Kinnier Wilson: Some Heredo-familial Diseases (I.) Pyramidal.
TUESDAY, 3.30 P.M., Dr. Critchley: Cerebral Vascular Disease (III.).
WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.
THURSDAY.—3.30 P.M., Dr. Carmichael: Myasthenia Gravis.
FRIDAY.—3.30 P.M., Dr. Brinton: Facial Neuralgia.
 Out-patient clinic daily at 2 P.M.
- WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.**
MONDAY, Feb. 10th.—10 A.M., Medical wards and skin clinic. 11 A.M., Surgical wards. 1.30 P.M., Gynecological wards. 2 P.M., Surgical wards, gynecological and eye clinics. 4.15 P.M., Mr. Green Armytage: Hormones in Gynecology.
TUESDAY.—10 A.M., Medical wards. 11 A.M., Surgical wards. 2 P.M., Throat clinic. 4.15 P.M., Mr. Wood Walker: Derangements of Knee-joint.
WEDNESDAY.—10 A.M., Children's ward and clinic. 11 A.M., Medical wards. 2 P.M., Eye clinic. 4.15 P.M., Lecture on anaesthesia.
THURSDAY.—10 A.M., Neurological and gynecological clinics. Noon, Fracture clinic. 2 P.M., Eye and genito-urinary clinics.
FRIDAY.—10 A.M., Skin clinic. Noon, Lecture on treatment. 2 P.M., Throat clinic.
SATURDAY.—10 A.M., Surgical and children's clinics, medical wards.
 Operations, medical and surgical clinics daily at 2 P.M. The lectures at 4.15 P.M. are open to all medical practitioners without fee.
- FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.**
MONDAY, Feb. 10th, to SATURDAY, Feb. 15th.—ST. JOHN'S HOSPITAL, 5, Lisle-street, W.C. Afternoon course in dermatology.—**BLIOMPTON HOSPITAL, S.W.** All-day course in chest diseases.—**CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W.** All-day course in gynecology.—**NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W.** Tues., 8.30 P.M., Mr. A. M. A. Moore: Injuries to Tendons, Muscles, and Joints. Thurs., 8.30 P.M., Mr. E. W. Riches: Kidney and Bladder.—Courses are open only to members and associates of the fellowship.
- SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, WEDNESDAY, Feb. 12th.—4 P.M. (St. James's Hospital, Ouseley-road, Balham, S.W.), Dr. H. Crichton-Miller:** The General Practitioner's Approach to Psychoneurosis.
- LEEDS GENERAL INFIRMARY.**
TUESDAY, Feb. 11th.—3.30 P.M., Dr. Vining: Some Problems in Connexion with the New-born.

Liverpool, Fazakerley Sanatorium.—Res. Asst. M.O. £200.
Manchester, Baguley Sanatorium.—Deputy Med. Supt. £500.
Manchester, Duchess of York Hospital.—Sen. Res. M.O. At rate of £125.
Manchester Victoria Memorial Jewish Hospital.—H.P. At rate of £120.
Metropolitan Hospital, E.—Hon. Surgeon. Also Surg. Reg. Middlesex County Council.—Tuber. M.O. £750.
Miller General Hospital, Greenwiche-road, S.E.—Cas. O. Out-patient Officer. Each at rate of £150. Also H.P. & H.S. Each at rate of £100.
National Hospital, Queen-square, W.C.—Res. M.O. £200.
New End Hospital, Hampstead, N.W.—Asst. M.O. £250.
Northampton County Mental Hospital, Berrynood.—Second Asst. M.O. £450.
Nottingham Children's Hospital.—Res. H.S. At rate of £150.
Nottingham General Hospital.—Cas. O. At rate of £150.
Portsmouth Royal Hospital.—H.P. At rate of £130.
Preston, Sharoe Green Hospital.—Sen. Asst. Res. M.O. Also Jun. Asst. Res. M.O. At rate of £200 and £100 respectively.
Princess Beatrice Hospital, Richmond-road, Earl's Court, S.W.—H.S. and H.P. Each at rate of £110.
Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Res. Anaesthetist. At rate of £100. Res. Anaesthetist and Dist. Res. M.O. At rate of £90. Also Asst. Res. M.O. At rate of £80.
Royal Chest Hospital, City-road, E.C.—Clin. Assts.
Royal National Orthopaedic Hospital, 234, Great Portland-street, W.—Asst. Res. Surg. for Country Branch. £250.
Royal Naval Medical Service.—Eight vacancies.
St. Andrew's Hospital, Devons-road, E.—Asst. M.O. £250.
St. Bartholomew's Hospital, E.C.—Dental H.S. £80.
St. John and St. Elizabeth Hospital.—Surg. Registrar. £100. Also Clin. Asst., Ear, Nose, and Throat Dept.
St. John's Hospital, Lewisham, S.E.—Med. Reg. to Out-patients. 50 guineas.
St. Leonard's Hospital, Hoxton-street, N.—Asst. M.O. £250.
St. Luke's Hospital, Sydney-street, S.W.—Asst. M.O. £250.
Salisbury General Infirmary.—H.S. At rate of £125.
Sheffield Children's Hospital.—H.S. At rate of £100.
Sheffield Royal Hospital.—Clin. Asst. to Ophthalmic Dept. Also Clin. Asst. to Ear, Nose, and Throat Dept. Each £300.
South Eastern Hospital for Children, Sydenham, S.E.—Jun. Res. M.O. At rate of £100.
Swindon and North Wilts Victoria Hospital.—Res. M.O. £150.
Wakefield, Middleton-in-Warfedale Sanatorium.—Res. Asst. M.O. £350.
Warwickshire County Council.—Asst. County M.O.H. £500.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Hon. Surgeon to Inoculation Dept.
West London Hospital, Hammersmith-road, W.—Half-time Pathologist. At rate of £300.
Westminster Hospital Annex, 66, Fitzjohn's-avenue, Hampstead.—Three Radiologists for Clin. Res. Work. Each £300.
Woodwick and District War Memorial Hospital, Shooters Hill, S.E.—H.P. At rate of £100.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Manchester, South East, Lancs.

Vacancies

- For further information refer to the advertisement columns
- All Saints' Hospital, Austral-street, West-square, S.E.—Res. H.S.** At rate of £100.
Archway Hospital, Archway-road, N.—Asst. M.O. £250.
Barbados General Hospital.—Sen. Res. Surg. £150.
Berley Urban District Council.—M.O.H. £800.
Birmingham, Ear and Throat Hospital.—Third H.S. At rate of £150.
Birmingham, Queen's Hospital.—Bacteriologist and Clin. Pathologist. £600. Also Res. Surg. Reg. £100.

NOTES, COMMENTS, AND ABSTRACTS

THE PHYSICAL BASIS OF
PSYCHONEUROSISPSYCHO-SOMATIC INTER-RELATIONS IN
THE LIGHT OF CLINICAL MEDICINE¹

BY SVEN INGVAR

PROFESSOR OF MEDICINE, UNIVERSITY OF LUND, SWEDEN

FOR centuries the relations between British and Swedish sciences have been close and intimate. I have only to recall my famous countryman, Emanuel Swedenborg, who spent many years here in England until he died in London (1772). Another brilliant representative of Swedish science, Carolus Linnæus, spent a happy and fertile time in this country. Sweden will always remain indebted to English science for its wonderful way of cultivating the spiritual heritage of these two radiant geniuses of the Swedish tongue, through the Swedenborg and Linnean Societies.

British medical science has had a great influence on medical progress in the world through its famous representatives of physiology. I think it is the generally accepted opinion throughout the world that English physiology has for a long time been the leading physiology—I only need to mention such names as Starling, Bayliss, Haldane, Barcroft, Dale, Hill, Adrian. The great progress of clinical medicine during the last decades is in the first place due to the progress in physiology. We have got into the dynamics of the different clinical symptoms, meaning for the patient better diagnosis and better treatment. No man has a greater influence in the evolution of clinical neurology than your Sherrington. Due to the consistent work of him and his school, the clinical neurology of to-day is no longer a mere description of different syndromes, it has become the science of the dynamics of the different nervous symptoms.

On this occasion I speak about the psycho-somatic inter-relations in disease, a subject that has been treated very exhaustively already in the literature from the philosophical, psychological, neurological, psychiatric, as from the viewpoint of general medicine. Recently Flanders Dunbar published a monograph of almost 600 pages with the title: "Emotions and Bodily Changes," quoting no less than 2251 books and papers on the subject. It is significant that Dunbar states in his conclusions at the end of his extensive book that "the time is not yet ripe for writing a text-book on psycho-somatic inter-relations. It is possible," he continues, "that a text-book will never be written," and there is really no endeavour towards synthesis in his book.

Such are the difficulties met in this field. I am treating the subject from my personal experiences as a representative of general medicine. The majority of the workers in this field have been neurologists or psychiatrists, but when neurotic disturbances of internal organs are in question, nobody is more certain to collect experience than the general clinician. The questions form an integral part of general medicine, and in the general clinic the material of so-called organic neurosis is concentrated. Many others who have theorised or

philosophised on the questions have not had the best material, neither has this material been examined according to the demands of the modern clinic.

The Influence of the Emotions

Our psychical life has in various ways a momentous influence on all corporeal functions. Experimental psychologists have convincingly established that even the simplest form of intellectual activity without being emotionally coloured, influences the blood pressure, the distribution of blood in the vascular system, and the tone of the muscles. That the emotions have a very powerful effect is now quite generally accepted and is proved both by clinical observations and experiments. In this connexion it is necessary to mention Cannon's investigations of the influence of emotional conditions on animals. These physiological experiments are naturally of the greatest interest, but the influence of the emotions certainly extends much farther than we can show by physiological analysis. When we see how anguish forces its victim to roam about, how it banishes sleep and the appetite, when we see the flow of tears, the cold sweat and the pallor, we know, without further evidence, that emotion is a very serious business, and penetrates through every fibre of the being. Emotion thus always signifies a strong general alteration in the somatic functions of the body. If, in this manner the effect of psychical influence on the somatic functions is so visible, we are in the first place interested in trying to discover to what extent diseases in the internal organs of the body can arise by emotions, that is, in a psychogenic way—by diseases is meant a change of the anatomical substratum implying an irreversible process, disturbing life manifestations.

As we know the vegetative nervous system innervates the smooth muscles in the internal organs particularly in the walls of the vessels and of the digestive tube, as well as the great glands, and thus it is to be expected that nervous disturbances will appear especially in the smooth musculature in the tubular organs, or in the endocrine glands. A very often quoted German writer, Alkan, has lately proposed a principle of classification along these lines, and indicates various ways by which emotion could cause anatomical changes. Through an abnormal innervation of the muscles in the tubular organs—for example the gut, a cramp or spasm arises in some place, producing a local ischæmia which, if sufficiently intense, leads to ulceration; he instances the gastric ulcer. From such a cramp, in certain circumstances a stagnation easily arises in the proximal part of the tube, which in its turn leads to dilatation, and so the characteristic distensions can come about. Again, sphincteric cramp of the gall-bladder leads to stagnation of the bile, and the resulting change of concentration might cause gall-stones, and, inasmuch as spasm leads to stagnation of infectious material, even severe inflammatory conditions can naturally evolve. So cholecystitis, cholangitis, and colitis by constipation have been explained.

This seems in fact a very simple and in many ways acceptable scheme, but the question immediately presents itself as to how this theoretical plan fits in with our clinical experience. We are furthermore confronted with the question as to why this abnormal innervation occurs in a definite organ, differing for different individuals, why one person gets a spasm in the gullet, another in the pylorus causing stagnation

¹ Lecture delivered before the Hunterian Society on Jan. 20th, 1936.

of food with vomiting, eructations, &c., another a spasm in the urinary bladder, another in the gall-bladder, and so forth. The psychogenic organ—selection in the somatic expression of the neurosis—is a fundamental problem which may be considered here.

The Psycho-analyst's Attitude

This question has especially been a subject of interest for psycho-analysts. They generally hold the view that as neurosis is to be considered as a general state of conflict so the manifestation of neurosis is a protest, and the choice of organ should have some sort of symbolical meaning. Differently talented people choose different musical instruments, similarly different temperaments choose different organs for their neurotic manifestations. That a disturbance in an organ really can sometimes denote a symbolic phenomenon created by pure psychogenic mechanisms, cannot surely be rejected. Reliable gynæcologists report, for example, how obstinate genital bleeding, or genital eczema, has been cured only after the removal of repulsive sexual psychical circumstances. A clinician must however be excused for not accepting a priori the symbolical interpretations of organic neurosis in their entirety, and for trying to fit them in with our further general knowledge of the pathophysiology of the organism.

Defining Neurosis: the Association of Organic Disturbance

If one wishes to define the term neurosis, I understand it as a disharmony of the nervous functions, and from this it is clear that the causes of neurosis must be various. All purely somatic injuries can cause neurosis, over-strain, chronic bodily disorders, intoxications (alcohol), infectious diseases, often cryptogenic. But especially everything which interferes with our will to live and to assert ourselves causes this functional disharmony. In this manner neurosis is the expression of a vital conflict. The more highly developed an individual is the more complicated is this conflict inclined to be. In the modern man one must seek the fundamental cause of neurosis in the social, moral, political, and religious field. It is clear that sexuality, which implies the tendency to lust of life in its highest potentiality must play a most important ætiological rôle. Here moral attitude, philosophy of life, temperament, the finest and most subtle differentiation of the personality are strongly decisive. But we can all be subject to conflicts, and it can undoubtedly be said that we all react neurotically to our conflicts. But from pronounced nervous disturbances, the great neuroses, the majority of us are however fortunately saved. The war has in a most convincing way brought to light, what was not so clearly known before, how our hereditary mass, our internal fundamental structure or constitution, plays a decisive rôle in morbid nervous reaction. All the horrors and psychical torments of the war did not succeed in producing any new nervous disease. Naturally nervous exhaustion was extremely common—not alone among the soldiers at the front—but this appeared generally benign, and when occasion for rest and recreation was found there was a spontaneous and rapid recovery.

We know how with organic brain diseases, typical paralysis or convulsions arise in the muscles of different parts of the body. In this connexion it is pertinent to ask if organic brain lesions also cause disturbances in the internal organs. Examining organic brain diseases from this point of view, one

is, in clinical medicine, instantly confronted with the fact that these occur astonishingly seldom. Organic brain diseases hardly ever cause nervous diseases of internal organs. The epidemic encephalitis, as we have learnt it in the last years, has its anatomical point of attack chiefly in the vegetative centres in the middle brain. One might, for instance, find in epidemic encephalitis characteristic changes in the organism in its entirety, which calls dystrophia adiposogenitalis to mind. In encephalitis there is furthermore often found an increase of salivary secretion and a change of the functions of the sebaceous glands, which gives the face an appearance of having been rubbed with fat, the so-called "oily-face," or the interesting disturbance of the water metabolism, diabetes insipidus, but localised disturbances of internal organs are not a characteristic feature of encephalitis. Neither Wimmer nor Economo tell about these.

It is likewise a clinical fact that organic disturbances play a very small part in epileptic attacks. These may consist of a vasomotor spasm in the brain cortex leading to violent functional discharge which shows itself in unconsciousness, violent muscular cramps, &c. During the fit the muscles of the urinary bladder in particular may contract. This might be in agreement with our knowledge of the bladder's representation in the brain cortex. But localised cramps in smooth musculature of other internal organs are not known to appear in the epileptic attack. It is true also of other serious organic diseases in the brain, for example, brain tumours, that they manifest themselves to a remarkably small extent in the internal organs.

Another circumstance which certainly does not lack significance in the consideration of the difficult psychogenesis problem is organic manifestations in hysteria. This disease also produces characteristic syndromes—paralysis, contractures, disturbance of sensibility, and so forth—which since the time of Charcot have been minutely studied. Modern research has shown that primitive nervous mechanisms released by emotion appear in the manifestations of hysteria. It is thus remarkable that in hysteria symptoms from the internal organs play such a small rôle in the clinical picture as they do. The tendencies of the hysterical personality make it understandable that phenomena like aerophagia followed by loud eructations are for certain individuals an instrument of self-assertion. The same likewise applies to hysterical vomiting. Such phenomena cannot be considered as organic neurosis in a proper sense. It is evident from all extensive compilations in medical literature concerning hysteria (Vorkastner and Kehrer) that hysterical heart, stomach, or intestinal diseases are not known with certainty, and that the hysterical mechanisms, with their tendency to protestation and self-assertion, have no tendency to influence internal organs.

The Great Endocrine Glands

In considering to what degree nervous disturbances of the greater endocrine glands really appear, it may first be stated that we have from the experience of clinical medicine no fixed evidence that diabetes can arise in a purely psychogenic way. For a long time it has been considered certain by some authors that psychic momentum can lead to diabetes: it was very often stressed that certain individuals living under strong psychic tension, business men and others with an anxious life, were disposed to diabetes. It has even been emphasised in medical literature that during great economic crises the

prevalency of diabetes increases—the blood-sugar in diabetes should increase in inverse proportion to the sinking of share prices. Similarly it is alleged that under certain emotional conditions sugar can appear in the urine. It would therefore not be far-fetched to suppose that if a primary psychogenic increase of the blood-sugar is fed emotionally for a long time, we can have degeneration into real diabetes. The experiences of the world war, however, again contradict this, as no definite psychogenic diabetic cases occurred. Umber as well as Gottstein, who have great experience concerning this disease, accentuate this very strongly, and another prominent investigator in the field of metabolic diseases—namely, von Noorden—says that only he who is born to get diabetes gets it. We have nowadays, it appears, the right to deny the existence of emotionally caused psychogenic diabetes. This does not of course interfere with the fact that nervous influences can have an aggravating effect on the disease in question. Everyday clinical experience tells us that. Amongst those who treat diabetic patients it is well known that the blood-sugar increases if the patient gets excited. Cannon found that sugar did not develop in excited animals after removal of the adrenals. Neither the Swedish investigators, Marcus and Sahlgren, nor the Danes, Nielsen and Jörgensen, have, in their extraordinarily exact observations, been able to cause a glycosuria in healthy persons. Widmark has not been able to demonstrate glycosuria in his students before examination. (He interprets this fact as a proof that he is too easy an examiner.) Malmros, in the medical clinic of Lund, has not been able, in such serious situations as the severe final examinations of students or before surgical operations, to find either sugar in the urine or an increase of blood-sugar.

What is said in this connexion about the pancreas also holds good for the thyroid gland. For a long time we have had a definite idea that Graves's or Basedow's disease was often caused by psychic shocks, fright, anxiety, or sorrow. Amongst others, Chvostek champions this idea in his big monograph on this disease.

We have ourselves, in Sweden, for a long time accepted the view, that Graves's disease attacks in the first place women with a nervously exacting profession, such as teachers. Experiences from the war, however, have not with any convincing clearness given support to the idea of a purely psychogenic Graves's disease. The frequency of war-time Graves's disease did not rise in a way corresponding to the emotional stress of the population. In the occurrence of Graves's disease, again the constitution definitely plays an important rôle. That emotional conditions on the other hand play an enormous part in the progress and course of this disease we already understand, as we know that thyroid hypersecretion is one of its main characteristics, and this has in itself a great stimulating effect on the brain, especially on the functions of the vegetative nervous system; and treatment of Graves's disease must be focused perhaps even more on the psychic state of the patient than on the purely somatic symptoms. Stoddard has emphasised that the symptoms of exophthalmic goitre and the anxiety neurosis are exactly the same.

Psychical Factors in Heart and Vascular Disease

An important group of neuroses which in later years in the modern clinic is decreasing in number are the so-called heart neuroses. Lately the prominent German clinician Matthes has treated this problem

and has accentuated the difficulty of relying on the diagnosis of heart neurosis in individual cases. In later years the electrocardiograph in particular has registered a number of disturbances in the heart's rhythm, which for a long time before were interpreted as nervous effects, depending on anatomical lesions in the myocardium. Heart neurosis was according to Kehrer a very little used diagnosis in the German army during the war. In most cases of functional heart disturbances, organic causes could be demonstrated, often among these, constitutional inferiority. The most prevalent of all nervous heart disturbances during the war were palpitations. The front soldiers living in anxious expectation concerning their fate, reacted simply with an increased frequency of the pulse. Sometimes even a low pulse frequency occurred. The effort syndrome of soldier's heart, or as it has been called in U.S.A. neurocirculatory asthenia, that was so to speak rediscovered during the world war, with dyspnoea, palpitation, and heartache is in some people the normal response to excessive fatigue, worry, or emotional stress, and to infection. The heart symptoms are only partial phenomena in a neurasthenic syndrome, and it is misleading and inadequate to consider it as heart neurosis. Dudley White states that there is no tendency for cases with this syndrome either to die prematurely or to develop heart diseases.

The diagnosis of heart neurosis has to take into account all the unmanifested lesions of the heart muscles, chronic septic diseases, degenerative sclerotic processes of the coronary vessels, and also disturbances in the internal secretions. When all these complicated and often subtle processes are properly considered there is not much room left for the conception of heart neurosis.

The influence of psychical factors on the vascular system is confirmed by the well-known fact that vasomotor phenomena play an important part in emotional reactions in general. One of the most common effects of emotions is, as we know, arterial hypertonia, and prolonged psychic tension undoubtedly also gives hypertonia of corresponding duration. The question arises if hypertonia so caused can after a time develop a real hypertension with its typical sclerotic alteration of the arterial system. The answer is by no means clear. Leading authors believe that hypertension begins as a nervous spasm of the arterial system leading to hypertrophy of the arterial walls and of the myocardium, with degeneration and pronounced arterio-sclerotic processes in the body not least in the kidneys. In this way some cases of nephro-sclerosis might develop. Many authors assert that arterial hypertension, so common in our modern times, is caused by psychic mechanisms. It is, however, necessary to state that no definite evidence has yet been produced for the pure psychical genesis, even if it must be regarded to a certain extent as probable. It must be emphasised that even if it has been clearly demonstrated that psychic stress has the effect of raising the blood pressure in a good many individuals there has not been found on the other hand a greater frequency in psychotic patients with depressive emotional states than in normal individuals. Researches of uniovular twins have lately demonstrated to what a large extent the constitutional factor acts in the individual cases in producing arterial hypertension.

Asthma as a Nervous Disease

It is a prevalent idea that bronchial asthma ought to be regarded as a nervous illness, indeed one

often finds it stated in medical literature that it should be treated purely psychotherapeutically. From researches in later years we have now a rather clear conception of the asthma attack as an allergic disease. In accordance with this, we regard it as a general biological reaction of the body to foreign matter, so-called allergens. The reaction localises itself in some individuals, by what is for us an unknown cause, in the respiratory channels. By experimentally induced anaphylactic shocks in guinea-pigs, lung changes directly analogous to those resulting from asthma in the human body can be obtained, also in animals after cutting all nerves to the lungs. From our clinical experience we know that psychical causes play a somewhat important part in initiating an asthmatic attack, and asthma patients are often markedly nervous persons. They belong to the vegetatively stigmatised, if I may use what seems to me an appropriate expression, coined by von Bergman to replace the less adequate conceptions sympathicotonia and vagotonia. Many facts indicate that nervous people with their generally increased reflex irritability, to the influence of surroundings also have a lower threshold for the evolution of allergic reactions. The first asthma attack leaves behind it, probably for ever, a biological change localised in the cells of the respiratory channels. This means a disposition that makes way for a nervous reflex action which afterwards probably can be set in motion in a purely psychogenic way. We know that asthma often causes a strong feeling of anguish or oppression in the patient. It is not illogical to suppose that in certain sensitive pre-disposed patients any disagreeable situation can by degrees induce an asthma attack even without primary allergens. It is highly uncertain whether the asthma attack may even in these circumstances be considered as a direct primary psychogenic reaction. What has been stated, however, does not interfere with the fact that psychotherapy must be given an important place in the treatment of asthma.

The Digestive Apparatus and Psychic Influence

It is a well-known fact that the activity of the digestive tube is to a great extent dependent on psychical influence. This has been proved experimentally in many interesting ways. Katsch observed in rabbits in which an inlaid celluloid window was substituted for part of the abdominal wall that the gut instantly pales and its normal peristalsis stops if the animal is disturbed while eating, frightened, or subjected to pain. When one feeds an animal a lively movement instantly occurs in the whole gut. In Cannon's cats the movement of the stomach stops when they are confronted by an angry dog, and sometimes it takes an hour before any signs of life reappeared in it. Similar phenomena are well known from our clinical experience in human beings; Heyer especially has been able to show by X ray that the functions of the human gut are obstructed under the influence of a depressive state of mind. It is commonly known that fear or great sorrow can cause vomiting reflexes. It is told of the Swedish King, Gustaf the Fourth Adolphus, that he reacted with intense vomitings on learning that he had been dethroned. Bennet and Venables found that in hypnotic subjects to whom suggestions of nausea were made there was an inhibition of the normal rise of the curve of stomach secretion of hydrochloric acid.

If the influence of psychogenic factors on the motility as well as on the secretion of the stomach

is verified in this way, the question then arises as to the extent these factors play in promoting diseases in the stomach. Here a retrospective clinical survey shows that the conception of a nervous stomach disease appears less and less during the last decades. As different subjective stomach symptoms, such as epigastric pains and pressure after meals, gastric hypersecretion, eructations, vomitings, &c., have been discovered to be due to anatomical causes, the gastric ulcer or gastritis, the diagnosis nervous dyspepsia, if not quite rejected, is nevertheless highly discredited.

Recently gastritis, in the examination of which the Danish clinician Knud Faber has done such estimable work, has again come into repute in the clinic. X ray investigations of the mucous membrane in the stomach, which has been worked out to a high degree of perfection by H. H. Berg, together with systematic researches on the gastric juice, and last but not least the introduction of the gastroscope, make it probable that inflammatory processes in the mucous membrane are much more common than we have been inclined to believe. Many new possibilities are thus opened up to the modern clinician to explain the diffuse and abstruse phenomena from the stomach as caused by organic lesions.

One observes from modern theories concerning nervous diseases in the stomach that readily as one formerly gave the diagnosis stomach neurosis, so reluctant is one nowadays to decide what shall rightly be called by this term. We must acknowledge that we have no definite knowledge as to the possibilities of psychical factors in causing primary irreversible processes in the stomach.

Constipation is the commonest of all functional disturbances in the colon. Regarding its causes it is clear that as psychical influences play such a dominating rôle, it must be straightaway regarded as a nervous disease. That joy improves the metabolism and peristalsis of the intestines, while sorrow has a depressing influence was already known to antiquity. It is well known that change of environment, for instance a voyage, is for many people an infallible cause of constipation. Regular living with regular habits play a vital part in the correct functioning of the intestines. We also understand how nervous influences affect the functions of the colon, from the fact that nicotine which has a stimulating influence on the sympathetic nervous system has a laxative effect. Many people improve the functions of the intestines by a morning cigar. Just as thyroid extract has a stimulating effect on the vegetative nervous system, so it also helps to stimulate the movement of the colon and is just the right medicine for certain cases of constipation. For us it is an interesting question as to whether anatomical lesions of the mucous membrane in the colon, such as colitis, can be caused in a purely psychical way. I think we may answer in the affirmative. If stagnation of the contents of the intestine continues sufficiently long, it will cause real inflammation of the colon with diarrhoea. It is an old theory that constipation is one of the chief causes of chronic ulcerative colitis and in the treatment of this disease great attention must above all be paid to the relief of existing tendencies to constipation. It is likewise known that a strong neurotic element can present itself in these patients.

Emotional influences on the functions of the intestines clearly occur in so-called nervous diarrhoea. Particularly women, but men also suffer from the fact that in situations which excite them or cause

fear the intestines react with increased peristalsis and secretion. A suitable name for this phenomenon is "situation diarrhoea." The situation naturally varies for different individuals. Certain people can only sit in an outside seat nearest to the w.c. in the theatre, the consciousness that the nearest way to the latter is clear is sufficient to set the intestines at rest. In other circumstances violent anguish and diarrhoea may occur.

Inasmuch as nervous conditions are reflected in the intestines so nervous disturbances often occur also in the bladder. It is well known that such disturbances make themselves felt in states of excitement.

The Influence of Psychogenic Factors : Summary

From what has been said it follows that from a critical study of the question whether psychogenic factors can directly cause irreversible processes in the organism, there is, according to modern clinical experience, no convincing evidence that it can be so. It has been stressed how organic lesions of the nervous system, even in the vegetative centres in the brain, to a surprising degree, leave the internal organs of the body intact, how also the purely psychogenic mechanisms in hysteria seldom disturb the internal organs, how serious organic diseases which are an everyday experience of the internist play a very small part in the asylums, among psychotic patients, but how the constitutional inferiority plays a vital part in causing neurotic reactionary conditions. It has also been emphasised that as the physiological analysis of disease phenomena is improved by the development of diagnostic methods, so the conception of organic neurosis is more discredited, and where we formerly supposed primary psychogenic mechanisms, we now know that the symptoms depend on primary anatomical processes in the organ which disturb its functions secondarily.

However, we will not claim that our knowledge of pathophysiology has advanced so far as to enable us to reject the possibility that psychogenic factors can sometimes under certain conditions really cause organic changes. Nevertheless it may be wiser to wait and see. Block proves in a reliable way that warts on the hands can be caused to disappear to purely suggestive remedies, by the same simple methods which for a long time have been used by old country women. It is stated by a series of authors that in suitable subjects cutaneous blisters could be produced by hypnotical suggestion. I must be forgiven for my scepticism. I have a strong feeling that the production of these suggested blisters should be the subject of further control experiments.

Anyhow the attempt to fit in disease phenomena in our knowledge of pathophysiology must be given due regard. Without further clear and solid evidence I feel we ought not a priori to interpret organic symptoms as psychical symbols—for instance, constipation must not be taken as a sign of covetousness, nor the convulsion of the epileptic attack be interpreted as a sexual act. Faithful to scientific methods, we must try to explain these and other similar phenomena as somatic expressions of certain released nervous processes in the body, where the organism in its manner of reaction is bound very closely to the nervous structures of its own within reach.

This does not in any way reduce the significance of psychical influence in disease, that is the emotions' importance in the course of any sickness. We must not forget that body and mind are a single unit.

The anatomical organic change produces morbid feeling experienced by the sick person, and this latter is of course a purely psychical process. Here the intimate reciprocity of mind and body is a simple reality. In this manner every disease which disturbs the vital processes is always a psychical process, for all experience contains some psychical element. It is also clear from this starting point that whatever idea is held concerning the genesis of organic symptoms the psychical influence can never be discounted. This conclusion allows free scope for neurotic modification of organic diseases.

We have now a fixed attitude to the interesting question of psychogenic organ selection. We are convinced that emotion is a wave which spreads over the entire organism; we can only see it represented in certain external phenomena such as a distracted expression, pallor, tears, trembling, and so on, but at the same time we feel certain that it is a deeply seated business of the entire organism. We understand that there may be a predisposed state of irritation and that the emotion fixes itself fast there. The fact that some organic lesion often was latent explains that it has for a long time been wrongly concluded that the emotion caused something, whereas it has only *unveiled* the cause.

This general conception induces in us an attitude that will prove highly useful to our patients—we must be very energetic in trying to find out the real cause of any complaint of the patient. If the patient has got some consistent and persistent trouble in any part of his body, it implies some organic lesion, and the symptom should not be discounted as psychogenic or functional and treated purely psychotherapeutically.

Neurosis has been described as a disharmony of the nervous functions, and maintained that neurosis is a vital conflict. It is true of life instinct that it never gives up; a man fights to the last for life. We understand one of the most characteristic marks of neurotic phenomena, intensity and frenzy. Neurosis is not a weakening of the nervous functions but an intensification in the play of reflexes.

That neurosis is the unmasking of an organic lesion means the setting in motion of pathological reflex activity which nearly always takes the form of a vicious circle, and that for the neurotic person is his greatest trouble. Nervous symptoms generate one another and like rolling snowballs they increase with every turn. How far-reaching the effect of this psycho-somatic interaction in neurosis is, in the individual case, depends on many things: the talents, temperament, religious disposition, personality of the person in question. Thus the treatment of neurosis must be very difficult; the situation cannot be really understood if the disturbed organic reflexes are treated as pieces in a puzzle play. Neurosis is a human thing and the organs cannot be treated without considering the entire man. It has recently been stressed from so many different sources that the doctor's profession is before all an art, and sometimes this has been stated in a way which betrays contempt for medical science. As a reaction against the so-called morphological attitude, which medicine has inherited from the great days of the cellular pathologists, this view may be said to have a certain authorisation. But medicine must always remain a true science, the science of human nature. Anyone who undertakes the treatment of nervous organic diseases must take into consideration the experience of clinical medicine and of all medical science; these have been collected with great labour.

THE DIONNE QUINTUPLETS

ALTHOUGH the appearance and daily life of these five attractive sisters has been made familiar to the world at large by the screen and daily press, considerable interest attaches to Dr. Allan R. Dafeo's more technical account of their early life and feeding. He has already (*Jour. Amer. Med. Assoc.*, 1934, ciii., 673) given an account of their birth and immediate treatment, and in the January issue of the *Canadian Medical Association Journal* he carries their medical history to the end of their first year.

Shortly after birth, the five infants were placed in a laundry basket and kept warm by means of blankets heated in the oven; later in the day it was possible to obtain a hot-water bottle, and on the third day an incubator was presented. Finally, there was a separate incubator for each infant; the temperature was at first kept between 87 and 90° F., and then at 84°, and by means of sponges soaked in hot water the humidity was maintained at between 50 and 55. Being born two months before term, the infants had the typical appearance of prematurity, breathed feebly and irregularly, and had frequent attacks of cyanosis and apnoea. Within the first week a cylinder of 95 per cent. oxygen and 5 per cent. CO₂ was obtained, and the gas administered as an "aperitif" before feeds and whenever there was cyanosis. This treatment was continued until they were three months old, by which time 14 cylinders, containing 80 gallons of the gas, had been used! Dafeo gives details of the feeding, and includes a set of weight charts that reflect every credit on all concerned. The Hospital for Sick Children, Toronto, supplied breast milk from the fourth day until the fourth to fifth month, in amounts finally reaching nearly a gallon a day. It is interesting that at one point one of the infants was getting 110 calories per pound body-weight, the daily caloric intake subsequently being gradually reduced to 40 per pound. So far they have been free from infection except for one attack of upper respiratory infection and otitis media, and an attack of gastro-enteritis which affected all five patients. After removal of the infants to the Dafeo Hospital, built across the road from their home in September, 1934, gown-and-mask technique was used continuously by all attendants.

Dr. Dafeo gives a humorous account of the recommendations for feeding and treatment that have reached him from all parts of the world—varying from burnt rye whiskey to sheep's dung in water. He does not emphasise the inevitable difficulties with which he must have been faced in a back-woods home of the type in which the infants were born, nor the continual intrusion of pressmen and sight-seers. One cannot fail to be impressed, however, with the patient, ingenious, and successful way in which the medical care of the infants has been applied.

BILATERAL ECTOPIC PREGNANCY

A case of simultaneous bilateral tubal pregnancy is reported by S. J. de Vletter (*Nederl. tijdschr. v. geneesk.*, 1935, lxxix., 5564). The patient, 35 years of age, had had two other children and four abortions. She was admitted to hospital complaining of acute abdominal pain and slight vaginal bleeding, the menstrual period being a fortnight overdue. The uterus was found to be slightly enlarged and the right tube could be felt as a distinct swelling. The left tube could not be felt. The diagnosis was made of a right tubal pregnancy, and as there were no urgent symptoms immediate operation was not undertaken. Next day there was another attack of pain, with signs of anemia, and operation was therefore performed. Laparotomy disclosed a ruptured right Fallopian tube, with the extended ovum (measuring about 1.5 cm.) lying outside the tube in a mass of blood clot. The rupture was in the isthmus of the tube, which was removed. The left tube was seen to be ruptured at the same spot and was also removed. The patient made an

uneventful recovery. Histological examination confirmed the presence of a bilateral ectopic pregnancy, both ova being apparently of the same age.

CERTIFICATION OF BLINDNESS

A CIRCULAR (No. 1520, 1d.) issued by the Ministry of Health to those responsible for the administration of the Blind Persons Act contains a warning that the method of testing visual acuity by cards is liable to give varying results according to the degree of illumination. Acting on the advice of the Council of British Ophthalmologists, they suggest that artificial illumination should be used in preference to daylight, and that the degree of illumination should be not less than 10 foot candles, setting out a method of obtaining this degree. This is however not one of the main difficulties with which the certifying surgeon is confronted. More important in doubtful or borderline cases of blindness than small differences in the acuity of central vision are defects in the visual field, already restricted when one eye is blind, the presence of nystagmus, and the question whether the blindness is progressive, stable, or capable of being improved by operation, treatment, or time. When all these have been considered, there may still be room for difference of opinion in the interpretation of the phrase "unable to perform any work for which eyesight is essential."

Births, Marriages, and Deaths

BIRTHS

- BAMFORD.—On Jan. 28th, at Ely, Cambs, the wife of Dr. Brian Bamford, of a daughter.
 BUCKTON.—On Jan. 29th, the wife of Dr. P. R. Buckton, of Wymondham, Norfolk, of a daughter.
 CATTERALL.—On Jan. 27th, at Devonshire-place, the wife of Dr. R. C. F. Catterall, of a son.
 GARLAND.—On Jan. 23rd, at Leeds, the wife of Dr. Hugh Garland, of a daughter.
 HENSMAN.—On Jan. 29th, at Devonshire-place, W., the wife of Dr. Stuart Hensman, Buckingham-street, S.W., of a daughter.

MARRIAGES

- KENNEDY—SHEPHERD.—On Jan. 25th, quietly, at Woodford, Essex, Michael Leo Kennedy, M.B. N.U.I., F.R.C.S. Eng., of Huddersfield, to Winifred Pearl Shepherd, of Highfields, Chigwell.

DEATHS

- BATTLE.—On Feb. 2nd, at Horsell Common, Woking, William Henry Battle, F.R.C.S. Eng., Consulting Surgeon, St. Thomas's Hospital, late of Harley-street, London, in his 81st year.
 CHRISTMAS.—On Jan. 30th, at Bozeat, Northamptonshire, Major R. W. S. Christmas, M.R.C.S. Eng., late R.A.M.C., B.E.F.
 FARQUHARSON.—On Jan. 30th, at Chelsea, Stewart Farquharson, M.B. Lond., aged 41.
 FORSBROOK.—On Feb. 3rd, 1936, at Victoria-street, London, S.W., William Henry Russell Forsbrook, M.D.
 LUNN.—On Jan. 27th, at Olton, Birmingham, Cyril R. Lunn, M.B. Birm.
 MACRAE.—On Feb. 2nd, at Newmill, St. Andrews, Farquhar Macrae, M.B. Glasg., consulting surgeon, Western Infirmary, Glasgow.
 MARNOCHE.—On Feb. 2nd, 1936, at 28, Albyn-place, Aberdeen, Sir John Marnoch, K.C.V.O., D.L., LL.D., Emeritus Professor of Surgery in the University of Aberdeen.
 PEARSE.—On Jan. 25th, the result of an accident, Frederick Edward Pearse, M.R.C.S. Eng., L.R.C.P. Edin., of Ripley, Surrey, aged 76.
 PRIDHAM.—On Jan. 27th, at Burgh, Lincolnshire, Charles Fortescue Pridham, B.Chir. Camb., M.R.C.S. Eng.
 ROB.—On Feb. 1st, 1936, in London, Joseph William Rob, O.B.E. M.D., of Outlands Park, Weybridge, aged 59.
 WAUGH.—On Jan. 29th, at Prenton, Birkenhead, Alexander Waugh, M.B. Glasg., aged 71.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

GREENOCK HOSPITAL.—Provost Bell, on Jan. 27th, cut the first sod on the site of the Rankin Memorial Maternity and Children's Hospital at Greenock. The hospital is being given to the town by Miss M. D. Rankin at a cost of £40,000 and it is expected to be finished within eighteen months. It will have room for 56 beds.

ADDRESSES AND ORIGINAL ARTICLES

THE TREATMENT OF
**PERNICIOUS ANÆMIA WITH DAKIN
 AND WEST'S LIVER FRACTION**

(ANAHÆMIN)

By C. C. UNGLEY, M.D. Durh., M.R.C.P. Lond.

ASSISTANT PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY,
 NEWCASTLE-UPON-TYNE; LEVERHULME RESEARCH SCHOLAR,
 ROYAL COLLEGE OF PHYSICIANS OF LONDON

L. S. P. DAVIDSON, B.A. Camb., M.D., F.R.C.P. Edin.

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF
 ABERDEEN; AND

E. J. WAYNE, M.Sc., Ph.D., M.B. Leeds,
 M.R.C.P. Lond.

PROFESSOR OF PHARMACOLOGY IN THE UNIVERSITY
 OF SHEFFIELD

IN 1926 Minot and Murphy¹ reported their epoch-making discovery of the value of liver in the treatment of pernicious anæmia. The difficulty which patients who were seriously ill found in eating 250 grammes of liver daily made it desirable to prepare concentrated extracts from the whole organ. The first successful concentration of the active fraction was achieved by Cohn, Minot, and their co-workers² who demonstrated that the daily oral administration of a powder weighing 12 g. (fraction G derived from 400 g. of liver) was as effective for blood formation as 250 g. of whole liver.

By elaborate chemical procedures this fraction was further purified, until material injected intravenously in doses as small as 0.025 g. daily would produce a maximal regenerative effect on the blood. General use of this product was not practicable because of its high cost, resulting from the loss of large amounts of active principle during fractionation. Accordingly Castle,^{3,4} using a simple solution of the fraction G of Cohn and also Gänsslen,⁵ prepared inexpensive products effective when injected intramuscularly in daily amounts derived from 5 to 20 g. of liver. Given by injection the extracts were 30-100 times more potent than when given by mouth. Attempts to isolate the liver principle in a state of complete purity have been hampered by the fact that the product is easily inactivated by chemical processes and by the lack of a reliable laboratory test for activity.

Recently a further stage in the concentration of the active principle has been announced by Dakin and West.⁶ For details of the complicated chemical processes involved the reader is referred to the original paper by these workers. The method employed in making the product used in the present investigation was essentially similar, fraction G (Cohn)² being treated with alcoholic calcium acetate to remove inactive material and subsequently concentrated by successive precipitation with ammonium sulphate, Reinecke salt, and finally ammonium sulphate again.

To this product the name Anahæmin has been given. It is a clinically potent light buff-coloured granular powder. When prepared from Cohn's fraction G a yield of 1 per cent. is obtained. The material is soluble in water and dilute alcohol, but insoluble in absolute alcohol and in ether. Dakin and West found that on hydrolysis it yielded an amino-hexose and a number of amino-acids—namely,

lysine, arginine, glycine, leucine, hydroxyproline and aspartic acid. Pyrimidine or purine bases were absent. The substance was slowly decomposed by pepsin and more rapidly by erepsin. Pancreatic juice had no effect upon it. Intramuscular or intravenous injections of 75 to 150 mg. have produced maximal reticulocyte responses.

A supply of anahæmin has been prepared by The British Drug Houses Ltd., under the direction of Mr. F. H. Carr, D.Sc., who originally suggested to Dakin and West the possible value of ammonium sulphate in the process of fractionation. The material was supplied in solution in ampoules containing 100 mg. per c.cm.

We were asked by the Medical Research Council to carry out the present investigation in order to determine the potency of the Dakin and West liver fraction, anahæmin, and to compare its hæmatological and clinical effects with those produced by other (less purified) concentrates. The advantages gained by simultaneous investigations at three centres were the increased number of cases obtained in a limited period and the correlation of independent observations.

It might be asked why, when potent preparations are already available, intensive research is still required into the purification of the active principle. There are at least three reasons why investigations in this direction are necessary.

(1) Increased concentration should permit the use of smaller quantities and longer periods between injections.

(2) Until the material is obtained in its pure state there is no possibility of its synthesis, a process which might lead to a marked reduction in the cost of treatment.

(3) There is the obvious desirability from the scientific point of view of investigating the influence of the pure substance not only upon blood formation, but also upon certain neurological and other phenomena associated with the syndrome of pernicious anæmia.

Progress is hampered by the scarcity of suitable cases of pernicious anæmia in relapse, and we take this opportunity of asking practitioners to refer such patients to hospital whenever possible. At the same time we acknowledge with gratitude the coöperation of those who have already permitted the investigation of patients under our care.

MATERIAL

A total of 36 cases has been treated, details of the first 23 being included in Table I. For brevity, clinical and biochemical findings other than those necessary for the present analysis are omitted, but every case was fully investigated and conformed to the criteria demanded for the diagnosis of Addisonian pernicious anæmia. In no instance was free hydrochloric acid present in the gastric juice even after histamine stimulation. Before commencing treatment a control period without therapy was observed. A diet low in meat and other sources of extrinsic factor was given during the period of investigation.

Results

CLINICAL FINDINGS

By the third to sixth day there was in most instances a feeling of well-being and a return of appetite, this subjective improvement frequently being less marked or delayed in patients with red blood-cell counts above 2 millions per c.mm.

Although in two instances soreness of the tongue persisted for more than 20 days, in most cases it had

ceased altogether by the end of the first week. This prompt relief of sore tongue by Dakin and West's liver fraction, which from its chemical nature and mode of preparation is unlikely to contain any of the known vitamins, is interesting in view of the theories of Hutter, Middleton, and Steenbock⁹ and of Groen,¹⁰

who suggest that the tongue changes in pernicious anæmia are due to deficiency of some portion of the vitamin-B complex.

Gastro-intestinal symptoms such as epigastric discomfort, vomiting, and diarrhoea usually cleared up in the first ten days. The rapid gain in weight¹¹

EXPLANATORY NOTES FOR TABLE I

"Days" in every instance refers to days after the commencement of treatment, the day of the initial injection being "0."

Reticulocytes.—Where the summit of the response was a "plateau" rather than a "peak," counts closely approximating to the maximum are given. The + sign in Cases 3 and 9 indicates that the actual maximum was probably higher than the recorded figures, the reticulocyte count not having been made daily in these two instances. The expected maxima are those calculated by Bethell and Goldhamer⁷ for intravenous injection of liver extract. Actual calculations for intramuscular injection are not yet available. The expected maxima for oral liver therapy (Riddle⁸) are given in italics.

Red blood-cell increases attributable to the injection of a single dose are printed in heavy type. At the time of the second injection in Cases 2, 4, 6, 10, 15, and 16 the red blood-cell increase following the first dose had ceased and the erythrocyte level remained below 3 millions per c.mm. These cases are included in the table for a second time (e.g., as Case 2 B) in order to show the rate of red blood-cell increase produced by the second dose. Secondary reticulocyte responses produced by second doses of material are given in parentheses (e.g., in Cases 16 and 16 B).

A column is included for "arterio-sclerosis and infection," since these factors have been shown to influence the response to treatment.

Under the heading "Remarks" the presence and the effect of treatment upon sore tongue, paræsthesia, and neurological phenomena are recorded. When not specifically mentioned such manifestations were absent. Further details of the neurological findings are given later in this paper under "Discussion."

Order of cases.—The cases have been divided into two groups: those with initial red blood-cells below 2 millions and those with initial counts at this level or above it. In each group the cases are arranged according to the amount of Dakin and West's fraction given in the first 10 days. Cases receiving similar amounts of material are put in order of 10 day increase of red blood-cells.

Sheffield cases: 5, 11, 19, and 2 others.

Aberdeen cases: 2, 3, 7, 9, 16, 20, 21, 23, and 6 others.

Newcastle cases: 1, 4, 6, 8, 10, 12, 13, 14, 15, 17, 18, 22, and 5 others.

The initial dose in Cases 8 and 10 and the first two doses in Cases 12 and 18 were given intravenously, but all other injections were made intramuscularly.

REACTIONS

When a second intravenous injection was given Case 18 suffered from pains in the limbs and back, flushing, and intense dyspnoea as if from bronchospasm. The symptoms ceased within half an hour of the injection. Under similar circumstances Case 12 had merely a flushing of the skin. Except for an occasional rise of temperature to 99° F. no other reactions were observed.

which frequently accompanies a remission, however induced, was observed in this series also.

Transient paræsthesiæ often brought on by exposure to cold and sometimes associated with obvious circulatory disturbances in the extremities—e.g., “dead fingers”—passed off within the first two weeks. More constant numbness and tingling, probably nervous in origin, decreased in extent and intensity after a variable period in every instance (see Table I.).

Objective neurological findings were observed in 12 instances. Cases 4, 10, 20, 21, and 22 showed merely diminished or absent vibration sense with or without depression or absence of deep reflexes; except for minor alterations in reflexes no significant changes were observed.

The effect of treatment in Cases 11, 13, and 17 showing evidence of subacute combined degeneration, but of relatively slight degree, is sufficiently indicated in Table I.

There were four patients with moderately severe subacute combined degeneration of the cord. Case 5 had less numbness and tingling, but showed no change in objective findings after 50 days, having received only 400 mg. in that time. In Case 14 paræsthesiæ diminished and gait improved, but at the sixty-sixth day the physical signs were little changed. Although still ataxic a patient (Case 9) who was unable even to stand can now walk for short distances without help. Spasticity has decreased but the plantar reflexes remain extensor. Incoördination and loss of cutaneous sensibility are less. Case 8 was remarkable in that after ten weeks the patient was free from paræsthesiæ, cramps, incontinence of urine, and dysfunction of the hands. The memory had become normal. The gait became quite steady and she was even able to run. Romberg's sign was negative. The plantar responses which until the eighth week had been clearly extensor thereafter became flexor in type. Depressed deep reflexes were more readily obtainable. Vibration sense returned in the spine, pelvis, and lower extremities with the exception of the toes, and cutaneous sensibility in the feet improved.

The fact that symptoms and signs of subacute combined degeneration improved during treatment with such a highly purified liver fraction is of considerable theoretical interest. Should the results be confirmed in a larger series of cases it will show that the hypothetical cord factor, if not actually identical with the hæmopoietic liver principle, must at least be allied to it chemically.

RETICULOCYTES

Up to a point, the height of the reticulocyte peak after the administration of any active substance increases with the quantity of material administered, but for a given initial red blood-cell count there is a maximum reticulocyte response which is rarely exceeded however great the amount given. The smallest quantity of material required to produce such maximal responses has been used as a measure of potency,¹² a matter to which further reference will be made. Table II. indicates the degree of reticulocyte response which followed the administration of varying amounts of Dakin and West's liver fraction anahæmin, figures for commercial liver extracts and for Dakin and West's own series being included for comparison. The reticulocyte response is described as good, moderate, or poor. Standard reticulocyte responses for the intramuscular route which was used in most instances are not available, but judging from published data¹² it seems that the maxima usually fall somewhere between those for intravenous

and those for oral therapy. An arbitrary line midway between the maxima for intravenous⁷ and for oral liver therapy⁸ has therefore been chosen, “good” responses being those which reached or exceeded this level. “Poor” responses are those which fall below an arbitrary level three-fourths of the maximum for oral therapy. “Moderate” refers to peaks falling between the two levels mentioned.

TABLE II
Reticulocyte responses according to dose

—	No. of cases.	Good.	Moderate.	Poor.
150 mg. or less ..	8	1 (12·5)	4 (50)	3 (37·5)
200 mg.	8	2 (25)	5 (62·5)	1 (12·5)
300 or 400 mg. ..	4	2	1	1
Total for present series	20	5 (25)	10 (50)	5 (25)
Campolon 10 c.cm. or Pernamon Forte 10 c.cm. (Ungley) ..	9	4 (44·4)	4 (44·4)	1 (11·1)
Campolon, Hepatex, or Lilly Ext. 2 to 5 c.cm. daily (Davidson) ..	6	3	1	2
Total	15	7 (46·7)	5 (33·3)	3 (20)
Dakin and West's series (75 to 150 mg.) ..	16	10 (62·5)	5 (31·25)	1 (6·25)

Percentages are given in parentheses.

A comparison with the figures for massive doses of commercial liver extracts shows that the percentage of “good” reticulocyte responses to 2 c.cm. of anahæmin (100 mg. per c.cm.) is lower than that produced by single injections of 10 c.cm. of Campolon or Pernamon Forte, or daily injections of Campolon, Hepatex, or Lilly's extract (see Table II.). There are not sufficient data available for doses in excess of 200 mg. The reticulocyte responses obtained by Dakin and West⁶ are referred to later.

INCREASE OF RED BLOOD-CELLS

It is well recognised that cases with a high initial red blood-cell count show a smaller rate of increase in erythrocytes than cases with a low initial level. An analysis of our data shows that this reduced rate of blood production is as apparent in cases starting with a high initial count as in cases which have reached a high level consequent upon previous treatment. When assessing the rate of red blood-cell increase in a given period produced by differing kinds or amounts of material, it is therefore desirable to confine comparison to cases with approximately similar initial levels. An idea of the rate of increase to be expected from adequate therapy may be gained by reference to Table III. which shows the response to oral and parenteral liver therapy in other series of cases. The initial level of red blood-cells in cases receiving anahæmin (1·55 to 1·57) was somewhat higher than in those receiving other liver extracts (1·2 to 1·37). Such a small difference in initial level can only have a slight effect on the rate of increase in 10 to 20 days (see Bethell's¹⁴ paper, Fig. 5). Details of the effects produced by varying doses of the Dakin and West fraction are given in Table I. Doses amounting to 150 mg. or less in the first 10 days were given in four cases having initial red blood-cell counts below 2 millions. There was an extremely rapid increase of red blood-cells in Case 3, a moderate increase in Cases 1 and 4, and a poor response in Case 2. Cases 15, 16, and 17 with initial counts over 2 millions showed very little response and Case 2B showed a

moderate response. The results are too variable and too few for purposes of comparison or statistical treatment.

Eight cases (Nos. 5 to 12) with initial red blood-cell counts below 2 millions received 2 c.cm. of anahæmin (100 mg. per c.cm.) as a single dose. The rise of red blood-cells was variable, lasting as a rule for from two to three weeks. On the average the increases in 10 and 20 days were similar to those produced by the administration of large amounts of

by the fact that the rates of increase are higher than those shown by the large number of cases in series v., receiving optimal amounts of liver extract intravenously.

The increase of red blood-cells in 20 days is distinctly less than that which follows the daily administration of extract 343 (fraction G of Cohn) derived from 500 or 600 g. of liver, and slightly exceeds that which is to be expected after the daily oral administration of extract 343 from 250 g. of liver¹³ (see Table III.). It may be concluded that the optimal single dose for rapid production of red blood-cells in 10 and 20 day periods is in excess of 200 mg.

Two out of three cases receiving 300 mg. at an initial red blood-cell count of over 2 millions (Nos. 21, 22, 23) had a greater increase at 20 days than the three cases with a similar initial level receiving 200 mg., but Case 4 B receiving 400 mg. from a red blood-cell level of 2.51 millions showed a poor response. Only three cases (Nos. 16 B, 13, and 14) had 300 or 400 mg. at an initial red blood-cell level sufficiently low for adequate test, and all three gave a good response. The data for doses of 300 and 400 mg. are not sufficient however to indicate whether in the average case such initial amounts are likely to be optimal for the production of red blood-cells at a maximal rate.

On the other hand, there were 11 patients with initial red blood-cell counts below 2 millions per c.mm. who received 100 to 600 mg. (average 359 mg.) in a period of 36 to 40 days. Cases with various initial red blood-cell counts below 2 millions receiving similar amounts of material tend to have much the same level after five weeks.¹⁴ It is significant therefore that not only are the rates of increase in this series of the same magnitude as those produced by large doses of campolon, but the final counts after 40 days are almost identical (Table III., Series III. and IV.). (It would of course be incorrect to conclude that 1 to 6 c.cm. of anahæmin were quantitatively equivalent to 30 to 82 c.cm. of campolon, because these quantities of campolon may have been more than were required to produce the effect attained.) Bethell's¹⁴ 79 cases receiving a regular weekly intravenous injection of 10 to 20 c.cm. of liver extract showed a considerably greater gain in 35 days than either of these series (Table III., Series v.).

Figures for red blood-cell increase are available in only 3 of the 20 cases reported by Dakin and West,⁶ but it is noteworthy that in their series 75 to 150 mg. were usually followed by a maximal reticulocyte response. It would appear possible that the material used in the present investigation may be somewhat less active than that prepared by Dakin himself. Dr. Dakin suggests¹⁵ as a possibility that when fresh liver is used instead of extract as starting material there may be less "denaturing" and increased activity.

The difficulty in drawing conclusions as to the potency of a product from hæmatological observations in small groups of patients must be fully realised. When reticulocyte counts are made only once daily it is unlikely that the maximum percentage attained will be observed in every instance.⁷ When, as in the present investigation highly purified materials are given and the intramuscular route is used, the irritant effects which may arise from non-specific substances present in material administered intravenously are likely to be less marked. But while we admit that in the majority of cases a maximal reticulocyte rise is followed by an excellent increase in red cells and a poor reticulocyte rise by little or no gain in red blood-cells, a study of Table I. clearly

TABLE III

Comparison of rates of increase of red blood-cells in cases of pernicious anæmia having initial counts of 2 millions per c.mm. or less

app. = approximate.

campolon in divided doses (Table III., Series i. and iv.) but were less than those which followed the single injection of 10 c.cm. of campolon or pernæmon forte containing from 2500 to 3500 mg. of solid matter* (Table III., Series i. and ii.). The difficulty of assessing the potency of preparations is well exemplified in Table III., Series ii. and iv. The 12 cases in Series iv. received from 20 to 30 c.cm. of campolon during the first week. The average gain in red cells in 20 days is less than that which followed the single injection of 10 c.cm. This cannot be explained as being caused by the effect of a single injection, nor on the grounds of differences in the initial red cell level, but only on fortuitous circumstances by which in series ii. a number of cases happened to be included which show a high grade of response. The average gain in 10 and 20 days in series iv. is of the same magnitude as occurs in series i., iii., and v. The contention that series ii. was fortunate in containing cases showing a high grade of response is supported

* Recent batches of Pernæmon Forte differ from those used in Series ii. in containing a smaller proportion of solid matter.

indicates that exceptions to this rule may occur. Thus while Case 2 showed a good reticulocyte response and little increase in red blood-cells, Case 11 had a poor reticulocyte response followed by a good gain in red blood-cells. In Cases 13 and 14 the patient with the smaller reticulocyte response had a more rapid increase in erythrocytes. A study of Table I. shows marked variations in reticulocyte response and red blood-cell gains in patients at similar initial levels receiving similar amounts of material. These variations may be quite independent of factors such as arterio-sclerosis and infection. This is well exemplified by the differences in reticulocyte response observed in Cases 13 and 14, 15 and 17, 21 and 22, differences for which no adequate explanation is forthcoming. Incidentally although we agree that in general cases with marked arterio-sclerosis or sepsis do badly (see Case 6) this does not hold good in every instance (see Cases 16 B and 13). A striking example of an optimal response in the presence of very severe sepsis has been published by one of us.¹⁶

It might be expected that age would influence the degree of response. Nevertheless analysis of the reticulocyte response and rate of red blood-cell increase in cases receiving Dakin and West's liver fraction showed no difference between those under and over 60 years of age. For this reason, although the age-incidence was higher in eight cases receiving 200 mg. of Dakin and West's liver fraction than in those receiving 10 c.cm. of campolon or pernaemon forte, the fact does not appear to account for the difference in response in the two series.

Since this investigation was commenced Strandell¹⁷ has reported the isolation of an almost colourless liver fraction; 2 mg. dissolved in water and injected intragluteally in patients with pernicious anæmia produced a marked hæmopoietic effect. The method of preparation has not yet been published.

Summary and Conclusions

A total of 36 cases of pernicious anæmia have been treated with Dakin and West's liver fraction, anahæmin. The material has been compared with other liver preparations in respect to the production of reticulocyte responses, increase of red blood-cells, and clinical improvement.

The data submitted emphasise the difficulty of assessing potency upon reticulocyte responses and red blood-cell increase in tests limited to a small number of cases. The results indicate, nevertheless, that anahæmin, as prepared by the British Drug Houses Ltd., is highly active for blood regeneration in pernicious anæmia. Total quantities of 1 to 6 c.cm. (100 to 600 mg., average amount 359 mg.) administered usually in divided doses, to 11 cases with initial red blood-cell counts below 2 millions per c.mm., were sufficient to cause an average increase of erythrocyte concentration amounting to 2.31 millions in 40 days. Good responses followed the administration of amounts sometimes as small as 10 mg. daily or 100-200 mg. as a single dose. For maximal reticulocyte responses, and for the production of red blood-cells at a maximal rate, larger doses were usually required. There is not sufficient data to assess quantitatively the potency of anahæmin as compared with other liver extracts, but in our experience no other liver extract given in the small amounts used in this investigation has produced such striking results. Preliminary observations suggest that this highly purified fraction may prove to be at least as potent as other liver extracts¹⁸

in the treatment of the neurological manifestations of pernicious anæmia.

It is a pleasure to thank members of the staff of the voluntary hospitals in Aberdeen, Sheffield, and Newcastle-upon-Tyne for their kind coöperation, and for allowing us access to their patients. In the case of one of us (C. C. U.) the work has been carried out with the assistance of grants from the Medical Research Council and under the tenure of a Leverhulme research scholarship of the Royal College of Physicians of London.

NOTE ON THE ANTI-ANÆMIC PRINCIPLE OF LIVER

BY JOHN F. WILKINSON, M.D., M.Sc., Ph.D. Manch.,
M.R.C.P. Lond., F.I.C.

HONORARY PHYSICIAN IN CHARGE AND DIRECTOR OF THE DEPARTMENT OF CLINICAL INVESTIGATIONS AND RESEARCH, ROYAL INFIRMARY AND UNIVERSITY OF MANCHESTER; HONORARY HÆMATOLOGIST TO HOLT RADIUM INSTITUTE AND CHRISTIE CANCER HOSPITAL, MANCHESTER

MUCH work has been carried out during the last few years in attempts to isolate and elucidate the nature of the principle present in liver that is responsible for initiating remissions in patients with pernicious anæmia. So far the identity of this liver principle remains obscure, although many concentrated highly purified extracts have been prepared. The slow progress has been due partly to the fact that every fraction can only be tested clinically on approved adequately controlled cases of pernicious anæmia,¹ and partly to the nature of the liver principle itself, which is extremely readily destroyed by many solvents and mild reagents—the more highly purified fractions being particularly sensitive.

In consequence of this sensitivity it has been difficult to standardise preparative methods of fractionation that would guarantee hæmopoietically active products every time. However, with the assistance and coöperation of Dr. F. L. Pyman, F.R.S., of the Boots Pure Drug Company Limited, Nottingham, I have been able to make considerable advances in this connexion.

A few months ago Dakin and West² described a method using Reinecke acid whereby they obtained a product of which 80 mg. was capable of producing maximal reticulocyte responses in patients with

pernicious anæmia. This was an important addition to our knowledge of the properties of the liver principle and I therefore attempted to repeat it.

Several difficulties were encountered resulting in the first few experiments yielding inactive products. These having been circumvented, however, successful products can now be prepared satisfactorily and I have been able to confirm Dakin's claim.

All the fractions have been examined clinically by the method already described¹—that is to say, each test case of pernicious anæmia was a typical uncomplicated one in relapse without having had treatment previously to complicate the picture. In every case a control period of 7–21 days was noted and the reticulocytes remained within normal limits. (These data are omitted from the Tables.) In each

and made available to me through Mr. Bacharach of Glaxo Limited; this also has been examined clinically. It will be seen that responses were obtained using doses of 4–8 c.cm. when administered intramuscularly; each cubic centimetre of this solution contained 10 mg. of total solid so that the dosages used were 40–80 mg. (Table II).

R.B.C. = red blood-cells. Hb. = hæmoglobin.

case reported in this paper no further subsequent reticulocyte response was obtained after those tabulated, which indicates that they were maximal responses. Table I. shows results from our experimental series W.D. 8 and W.D. 9, selected to illustrate the repetition of Dakin's method. It will be seen that maximal reticulocyte responses have been obtained with doses of 58–120 mg. of these fractions when given intramuscularly. Thus my results confirm the claims of Dakin and West that Reinecke acid can be used further to purify the anti-anæmic liver principle, but a good deal of active material is lost during the various stages of these chemical manipulations.

While these experiments were in progress Strandell³ reported good hæmopoietic responses using specially fractionated liver products (details of which have not yet been published), and claimed maximal responses with doses of only 0.002 g. He kindly sent me some of his unpublished results in connexion with this, and at the same time an experimental quantity of a highly purified liver fraction (N.S.G.L.1) similar to those he had been using was obtained by

Having successfully repeated the Reinecke acid method of fractionation several times, I have now introduced it as a step in our methods of fractionation. This has been done by (1) carrying out the Reinecke acid separation first and then subjecting the product to further fractionation, and (2) by applying the Reinecke acid separation to the products obtained by our own methods. Again these have been carried out on a sufficiently large scale by Dr. Pyman so that adequate supplies have been available for trial.

In series W.D.7, shown in Table III., it will be seen clearly that the potency of the final product

has been greatly increased, since maximal responses have been obtained consistently with total doses of only 18–36 mg. representing an original amount of 666–1332 g. of fresh liver. The product thus obtained was colourless and was administered in aqueous solution. Further fractionation is in progress and I hope at a later date to report fuller details.

SUMMARY

The fractionation of liver extracts containing the anti-pernicious anæmia principle by means of Reinecke

acid to yield a more highly potent fraction has been confirmed. Using this method products have been obtained of which 58 mg. produced a maximal reticulocyte response and a rapid remission in a patient with pernicious anæmia. Applying this method to other methods of separation a further increase in hæmopoietic potency has been secured so that as little as 18 mg. of the product have been sufficient to initiate a maximal reticulocyte response and rapid remissions in pernicious anæmia.

This work has in part been supported by a grant from the Medical Research Council.

THE PROGNOSIS AFTER INFARCT OF THE HEART

A CLINICAL STUDY

BY JOHN COWAN, M.D., D.Sc., F.R.F.P.S.

CONSULTING PHYSICIAN TO THE ROYAL INFIRMARY, GLASGOW

THE dramatic symptoms which sometimes occur when a coronary artery becomes blocked, and the not infrequent sudden termination of life, have led to a pessimistic outlook in these cases. But pathological experience has shown that cardiac infarcts are not necessarily immediately fatal, and that recovery may ensue. In Moritz and Beck's¹ series of 94 cases in which a main coronary artery had been occluded only 14 died after the first block. Accumulating clinical experience points in the same direction. Parkinson and Bedford² state that if the patient is alive when seen after the occurrence of an infarct recovery is more likely than death. Reasonable health may be maintained subsequently even for many years. Cases have been reported where the patient lived for seven,³ eleven,² thirteen,⁴ fourteen,⁵ seventeen,⁶ and twenty⁷ years.

Abrupt closure of a healthy main coronary artery causes sudden death, but if the closure is gradual anastomotic developments may take place in the neighbouring arteries and prevent serious results. Clifford Allbutt⁸ examined a heart where the orifices of the coronary arteries were so utterly obliterated that their very site was indefinable, and yet the myocardium was normal. Leary and Wearn⁹ report a case in which the orifices were almost completely closed and the muscle normal; and another case where the right coronary artery was blocked and the orifice of the left artery greatly narrowed, yet again with normal cardiac muscle. We have examined the heart of a man, aged 73, whose right coronary artery was occluded for about an inch, immediately after its origin, the only result being a small area of ischæmic fibrosis, not due to infarct, near the base of the right ventricle.

As a rule block takes place in a coronary branch and not in a main trunk, and the possibilities of satisfactory anastomotic developments are greater than if a main artery is affected. It seems that infarct is rarely due to closure of a single vessel. Saphir and his colleagues,¹⁰ examining with meticulous care 30 cases of infarct, failed to find a single case in which but one artery was affected. Two might be completely closed, or one blocked and the neigh-

bouring arteries grossly narrowed. Multiple lesions are necessary to produce an infarct.

The size of infarcts varies. They may be large or small. The gross lesions, affecting large areas of the myocardium, were those which first attracted clinical attention, but we are now recognising the lesser lesions. In the gross lesions the early symptoms are severe and persist for some time. In the lesser lesions the early symptoms may be severe but of short duration, or of comparatively mild type. Thoracic pain is not invariably present. Pain may be referred to the abdomen or wholly absent. Sudden cardiac collapse or an attack of dyspnœa may be the only sign of infarct.

The prognosis in cases of cardiac infarct is difficult to assess. Sudden death, without warning, may be the sole clinical sign of a coronary block. In the major attacks half the patients die at the outset, or within the next month. Of those who survive some never regain health, and die of progressive cardiac failure after a variable period. Others regain their health and live, even for many years, in fair comfort. There is little available information regarding the ultimate issue in the last groups, so we have examined the clinical records of 66 patients, 58 men and 8 women, who had had an infarct of the heart and survived for more than six months afterwards. This period was chosen as we are concerned with the late results of infarct, and recovery is rarely definite before six months have elapsed. The records are necessarily incomplete for 33 of the patients are still alive. Forty-four patients have lived for more than two years, one of them for ten and another for fourteen years. Thirty-eight resumed their work, which, however, as one would anticipate from their age, was never manual and could usually be regulated according to their physical needs.

Thirty-three patients are still alive, more than six months after an infarct. One patient whose infarct occurred *nine months* ago has never regained health. He has had several strokes and has uræmic symptoms.

TABLE I

Showing the present health of those patients who are still alive

—	16	12	4	33

* 1 unknown.

Eight patients have survived for more than *one* year. One of them has recently had a recurrence of cardiac symptoms. Four are in fair health for their years, and lead a quiet life without discomfort. Three are in good health, two in active work. One rides quietly and shoots driven birds. Another is paying visits in the U.S.A. Four have lived for more than *two* years. Three are in good health and lead their usual life, which in one case is very active. The fourth is in fair health, but resents his necessary abstention from golf. Eight have survived for more

than *three* years. Four, in reasonable health, are still at work. One has benefited by removal of gall-stones. Three are in reasonable health but have retired from business. The other is still alive, but as he has left the district his activity is unknown. Three patients have survived for *four* years. Two are leading active lives. The third, who is in fair health, has retired from business. Eight patients are alive *five* years after an infarct. One has had a recurrence of cardiac symptoms recently, and is forced to lead a quiet life. Another has never recovered his health. He has had a stroke, and a foot removed for gangrene; the other foot is now affected. Three are in fair health, leading a quiet life. Three are active in business, two of them playing golf as well as ever, though their standard may not be high. One patient is still alive after *six* years and works hard at his business.

Sixteen of these patients resumed their ordinary occupations after an infarct. Twelve are in fair health. The health of the remaining four is poor.

Thirty-three patients have now died. Seven died *within a year* of the first attack. Five of them never regained tolerable health, but two returned to work, one dying when shaving, the other in his garage. Six patients died in the *second* year. Three never regained tolerable health, but three resumed their ordinary avocations. Five patients died in the *third* year. One was never well and died from uræmia. The other four resumed their usual habits, two of them undertaking arduous work. Three died in the *fourth* year. Two were never really well. The third continued at work until the onset of a pulmonary tumour. Three died in the *fifth* year. All resumed their work. One died without warning in his sleep, one from a stroke, the third from pneumonia. Four died in the *sixth* year. All resumed their work. One patient died in the *seventh* year, having continued at work fairly steadily in the interval. He died in the bathroom within a few minutes. One died in the *eighth* year, after nearly five years of strenuous work. One died in the *ninth* year. He worked hard for many years and played golf. He died in his sleep some months after a successful operation for gall-stones. One patient lived for *ten* years after his first attack, and for five after the second. A third attack proved fatal. One patient recovered from his first attack and worked hard for the next five years, subsequently taking life easily. He had a slight recurrence of cardiac symptoms nine years after the first. He died slowly from cerebral softening *fourteen* years after the initial symptoms.

Twenty-two of these patients resumed their ordinary avocations for a time after an infarct. In at least ten cases the work was arduous. Several played golf, shot, climbed hills, &c., without difficulty.

Patients who have had a cardiac infarct do not always die from cardiac failure. In Parkinson and Bedford's² series 21 of 83 cases, examined post mortem, died from other than cardiac causes. In this series 24 patients died from cardiac failure, 14 slowly and 10 suddenly. But 2 patients died from strokes; 2 from embolism, of a cerebral and of a femoral artery; 2 from tumour; 1 from pneumonia; 1 from senile decay. The cause of death of the other patient could not be ascertained.

The occurrence of a cardiac infarct may be merely a phase of a general disease. One patient had a stroke in 1921, a cardiac infarct in 1922, and a second, fatal, stroke in 1925. He had no cardiac

symptoms save at the time of the infarct. A lady complained of intermittent claudication in 1930, had a cardiac infarct in 1931, a right hemianopia in 1932, and a second, fatal, cardiac infarct in 1933. Another patient, who is still alive, has never been well since his infarct in 1932. He has had a stroke, and one foot had to be amputated on account of senile gangrene in 1934. The other foot is now affected.

In some patients disease in organs other than the heart complicates the picture and the outlook. One patient suffered from cholecystitis in the spring of 1930 and from a cardiac infarct in the autumn; in 1931 from jaundice; in 1932 from cardiac, hepatic, and cerebral symptoms, the latter probably due to embolism; in 1933 and 1934 from recurrences of his hepatic symptoms, which necessitated the removal of gall-stones in July, 1934; in January, 1935, from convulsions. He is now in better health than for many years, and active at business. Gall-stones are not uncommon in this group of cardiac disease. Operative interference is, as a rule, badly borne, but we have seen several patients who were benefited. Renal and diabetic symptoms may coincide, and occasionally dominate the outlook. One patient, who is not included in this series, was admitted into hospital on account of uræmic symptoms of some months' duration. He died in coma. Post-mortem examination revealed cirrhotic kidneys and a greatly enlarged heart, with aneurysm of the anterior wall of the left ventricle. Three weeks before his death his systolic blood pressure was 160 mm. Hg. There was a minimal œdema of his feet on admission, but it soon disappeared and did not recur, so the sole evidence of cardiac insufficiency lay in the presence of symptoms of renal inadequacy.

In the presence of symptoms of cardiac insufficiency the prognosis must be based upon the symptoms as they emerge, day by day, as in cases of cardiac weakness due to other causes. In cases where recovery has ensued after a cardiac infarct the prognosis must be based upon all the data that are procurable, always remembering that sudden death is not uncommon in these patients and may occur without warning. An old gentleman, who had had a cardiac infarct five years previously from which he had made a good recovery, completed his usual day's work, took his dogs for an airing, and went to bed, where he was found lying dead in the morning. Another patient, whose infarct had occurred eight years previously, who had had gall-stones removed some months before, was met casually one afternoon. He told us that he was very well and resuming his work gradually. After dinner he played a game of cards and went to bed. He died in his sleep.

In this series nine patients are alive more than six and less than twenty-four months after an infarct. Two are active at work and straining at the leash; five are in fair, and two in poor, health. As the issue in this group is still uncertain we have omitted them from our figures. Prolongation of life for two years or more seems to indicate that the original lesion has healed, and that danger lies in the underlying pathological state rather than in the past infarct; in the possibility of the occurrence of a fresh lesion rather than from progressive changes in the ancient one. Thirteen patients died within the first two years; 44 have lived for more than two years. A comparison of the data in these two groups is shown below in the attempt to estimate the favourable and the unfavourable factors as regards continuance of life.

Age of the patient.—The younger patients have the better outlook. Levine's experience¹¹ agrees. But the prognosis is not good in the syphilitic group, with aortic incompetence and narrowing of the coronary orifices, whose symptoms tend to arise in the fourth and fifth decades. The more ample anastomoses of the coronary arteries, which normally develop as age increases, are evidently unable to cope with the extra work which a coronary block imposes upon the neighbouring arteries.

TABLE II

Data derived from the examination of 57 patients, at a variable period, after the occurrence of a cardiac infarct. Forty-four patients lived for more than two years afterwards; 13 died within two years.

	Duration of life.			Duration of life.	
	More than 2 yrs.	Less than 2 yrs.		More than 2 yrs.	Less than 2 yrs.

Enlarged	24	10	Aortic diastolic murmur ..	—	2
Not enlarged ..	20	3	Syphilis (?)	5	2

Previous health of the patient.—There is little difference in the data of the two groups. The result evidently depends more upon the extent of the local lesion than upon the general health of the patient, though any deterioration of the general health must react unfavourably upon the process of healing.

The occurrence of attacks of angina pectoris prior to the infarct does not seem to affect the ultimate result. Carey Coombs¹² and White and Bland¹³ agree. One could conceive that the occurrence of coronary narrowing in the past would facilitate the anastomotic developments required when an artery becomes blocked. The continuance of anginous attacks, however, predicates that anastomotic developments have not been effective. Saphir's observations,¹⁰ too, show that infarct is a matter of multiple arterial lesions; and any damage to one part of the myocardium must necessarily augment the strain upon the rest of the cardiac muscle.

Mode of onset of the illness.—In some cases an infarct occurs in a man whose health was apparently perfect. In others minor symptoms have preceded the occurrence of the infarct. The results in the two groups seem similar.

Severity of the initial symptoms.—If the doctor in attendance at the time of the initial attack thought that the patient was dying the case has been indexed as severe. The results in those patients whose initial symptoms were severe are less favourable than those in the second group. The difference probably depends upon differences in the extent of the area which is affected, or upon the rapidity of the development of the cardiac ischaemia.

Physical data.—*Enlargement of the heart* is of evil significance, whether due to hypertrophy or to dilatation. The former indicates pre-existing strain upon the heart; the latter a failure of the surviving muscle to compensate the loss of some muscle cells. *A high blood pressure* is unfavourable. It must be borne in mind that we are now considering the state of affairs some time subsequent to an infarction. In the early days a low blood pressure is an unfavourable sign as Harrington and Wright¹⁴ and Hay⁴ state, for it is an indication of myocardial failure. A lessening pulse pressure is particularly ominous. But when convalescence has been attained the case is different. A normal blood pressure suggests that the cardiovascular system is fairly sound, while a high blood pressure suggests the opposite conclusion, and in any case throws a heavy strain upon a damaged myocardium. The large number of patients with *normal retinal arteries* corroborates the idea that coronary block is most frequently a matter of local arterial disease—i.e., atheroma—rather than due to the diffuse affection, arterio-sclerosis. It is impossible to assess the influence of *chronic valvular disease* in a clinical series as the significance of a systolic murmur is often obscure. No case of mitral stenosis is included. There were two cases of aortic incompetence. One patient was aged 76, and generally degenerate, with Cheyne-Stokes breathing, pulmonary infarctions, and copious albuminuria. The lesion in the other patient was possibly syphilitic. He was aged 63; dissociation was present at one time. The first patient died seven months after the infarct; the second lived for nearly a year and a half. *Electrocardiograms* were taken in 50 cases in this series and showed various abnormalities. The records are too scanty to afford useful information as to the relative importance of the different defects, but a normal record is evidently a favourable sign. Inversion of T in all leads and flatness of all T's are unfavourable.

The occurrence of an attack of *syphilis* in the past does not necessarily prove that the cause of the cardiac infarct is syphilitic. Seven patients in this series had probably suffered from syphilis. The duration of life in these patients seems to be little influenced by this factor.

The prognosis after the occurrence of a cardiac infarct is better: among the younger patients; if the initial attack has been moderate in its severity; if the blood pressure is not unduly high; if the heart is not appreciably enlarged; and if the electrocardiogram is normal in character.

Two other factors are important elements in the prognosis: the care that is taken at the time of the infarct, and the reaction of the sufferer to his disability.

"Cure" of an infarct depends upon the development of satisfactory arterial anastomoses around the lesion. The possibilities are considerable but their development is slow. Strain upon muscle cells so long as they are inadequately nourished must be avoided. Our best results have been attained by keeping our patients at absolute rest for a couple of months, permitting a very gradual resumption of physical activities during the next two months, and then a very gradual return to the ordinary habits of life. Success, too, depends largely upon the coöperation of the patient. The well-balanced individual, of good physique and firm muscle, accepts the situation and does his best to aid. The irritable podgy fellow, flabby of brain and muscle, resents the necessary restrictions and cramps the cure. Social and business

commitments may occasion difficulties, but they can be surmounted when the patient realises the nature of his illness, and the nature of the cure. All can recall unfortunate results of a too early return to ordinary activities.

The occurrence of a cardiac infarct occasions grave danger to life, but if the patient survives the onset satisfactorily he has a fair chance of reasonable health even for many years.

We must acknowledge, with grateful thanks, the kindly help of our colleagues who have supplied us with many of the data on which this paper is based.

SOME OBSERVATIONS ON EXPERIMENTAL RENAL SECTION

By J. GRAY, M.Chir. Camb., F.R.C.S. Eng.

FELLOW IN SURGERY AT THE HENRY LESTER INSTITUTE AND
HON. SURGEON TO THE LESTER HOSPITAL, SHANGHAI

THE effect of hemisection of the kidney is still a matter of dispute. With increasing accuracy of diagnosis the indications for this operation in man have become very few, but there may still be occasional cases in which, despite all investigation, uncertainty exists, and such an exploration might be desirable. The question arises whether it is justifiable, and I felt that it would be of interest to study experimentally the effects of the operation upon (a) the incised kidney and (b) the remaining normal kidney.

INVESTIGATION

Twelve bitches were subjected to a preliminary cystoscopy in the course of which 5 c.cm. of 0.4 per cent. indigo-carmin was injected intravenously and the ureteric efflux from each side noted. (This method of investigating the renal function was chosen because it was found to be the most practicable. It had originally been hoped to catheterise the ureters and collect specimens from each side, but this proved too difficult to perform with certainty.) After a few days' interval the kidney on one side was divided completely from pole to pole until the pelvis was laid open. In order to control the hæmorrhage, a Crile's clamp was placed on the renal pedicle before the incision was made. The two halves were then brought together by two or three mattress sutures (catgut No. 2) passing through the parenchyma, three being usually required. The operation was completed with all speed, seldom occupying more than five minutes and never more than ten, in order to avoid the effects of prolonged anoxæmia. (A clamp on the pedicle would be used in clinical practice, and it was felt that the experimental operation should approximate as closely as possible in all details,

although otherwise it might have been better to avoid it.) After removing the clamp any further oozing was controlled by pressure with a hot gauze. The renal capsule was sewn up separately, the kidney replaced, and the wound closed. This was the operation performed on the first 6 dogs. The second 6 dogs had an identical operation except that the halves of the kidney were brought together by the use of Lowsley's ribbon catgut inserted, in the way he describes, through the capsule and carried round the kidney. By this method the objection that strangulation of tissue, including blood-vessels, would occur is eliminated, and so this operation should be the better one to perform. This investigation was undertaken partly, therefore, to compare the results of the two methods.

After the operation the animals were cystoscoped as far as possible at monthly intervals, using exactly the same technique with regard to anæsthesia and dose of dye as on the first occasion. Particular attention was paid to the time of appearance and concentration of the drug at each ureteric orifice.

At the end of three months the animals were anæsthetised with Luminal, laparotomy was performed, and catheters were passed into the ureters. Phenolsulphone-phthalein (1 c.cm.) was given intravenously and specimens collected from both kidneys. In practice it was found necessary to give 250 c.cm. of saline intravenously to promote diuresis or no specimens could be obtained. This, while interfering with any determination of total renal function, would not invalidate a comparison of that of the two sides, which was here required.

RESULTS

Table I. gives details of the operation and results; Table II., and the ensuing text, summarises them. It will be seen that 4 dogs died. One of these (No. 39) was suffering from other conditions which may have been partly responsible for death, but in any case the kidney was completely destroyed so that from the point of view of this operation it represents a failure. One other had complete atrophy, so that 7 survived with functioning kidneys. Of these 7, 5 had changes of greater or lesser degree but did not show progressive impairment or degeneration during the period of observation.

Renal Function.—The results obtained may be summarised as follows:—

(a) *Injured kidney.*—Eight showed marked impairment in one or other test. (See Table I., Nos. 15, 17, 20, 30, 35, 36, 37, and 39.) Three showed slight impairment in one or other test (Nos. 16, 19, and 29).

(b) *Sound kidney.*—Eight showed increased function (Nos. 15, 16, 19, 20, 29, 30, 37, and 39).

The most interesting feature was the apparent increase of concentration in the indigo-carmin excreted by the sound kidney; although given under identical conditions the dye was excreted in a shorter time and stronger concentration than before the operation. Along with this there was usually evidence of impairment in the operated kidney, so the conclusion can hardly be avoided that the sound one was doing more work because of the injury to the other.

Pyelography.—It will be seen from Table I. that—

Six showed marked deformity of the pelvis on the operated side (Nos. 15, 16, 17, 20, 29, and 30).

Two showed slight deformity of the pelvis on the operated side (Nos. 19 and 35).

Four were not investigated. The two cases of hydro-nephrosis fall into this latter group.

TABLE I.—OPERATIONS AND RESULTS

Dog.	Operation.	Cystoscopy. Time of appearance of dye (minutes).		Pycelography.		P.S.P.	Result.	Post-mortem and histological examination.
		Before Op.	After Op.	Intravenous.	Retro- grade.			
15	Mar. 9, 1934. Lt. side, 3 mattress sutures.	Rt. 6 Lt. 4.	(1) Rt. (conc.) 2½. Lt. 7. (2) Rt. (conc.) 2½. Lt. 5.	Rt. visualised. Lt. not visualised.	No abnor- mality detected.	—	Died June 20.	Lt. kidney shows area of destruction of tubules particularly in cortex. Prussian blue injected into aorta demonstrates rt. vessels well filled. Lt. side not well filled and avascular areas related to the scarred tissue.
16	Mar. 15, 1934. Rt. side, 3 mattress sutures.	Rt. 3½. Lt. 4½.	Rt. 4½. Lt. (conc.) 4.	—	Rt. pelvis abnormal in contour.	Rt. 20%. Lt. 25%.	Killed June 27.	Rt. kidney deformed (Fig. 1). Section shows areas of scarring in cortex and medulla with destruction of blood-supply as demonstrated by injection of carmine-gelatin.
17	Apr. 3, 1934. Rt., 3 sutures.	Failure.	Failure.	Rt. small pelvis not visualised well suggests poor function. Lt. pelvis visualised well.	Alt. in size and shape of rt. pelvis (Fig. 2).	Rt. 20%. Lt. 30%.	Killed Sept. 4.	Rt. kidney atrophied less than half the size of left. Section shows areas of destruction of tubules with deficient blood-supply in these areas as demonstrated by injection of carmine-gelatin into aorta (Fig. 3). Vessels in lt. also better filled than in rt.
18	Mar. 19, 1934. Rt., 3 sutures.	Rt. 6. Lt. not seen.	—	—	—	—	Died Mar. 25.	Rt. kidney complete hydronephrotic shell and full of blood (Fig. 4). Section: hydronephrosis and hæmorrhage.
19	Mar. 27, 1934. Lt., 3 sutures.	Rt. 8. Lt. 6.	(1) Rt. 5. Lt. 7. (2) (conc.) Rt. 4. Lt. 7. (3) (conc.) Rt. 4. Lt. 7.	Lt. pelvis ureter visualised clearly even better than right.	Lt. pelvis shows some abnor- mality of contour.	—	Killed Sept. 14.	Lt. kidney much smaller than rt. and softer in consistency but otherwise looks normal. On section there is marked destruction of tubules in the cortex, scarcely any normal tissue being left.
20	Apr. 9, 1934. Lt., 3 sutures.	Both 4.	(1) Rt. (conc.) 3½. Lt. 4. (2) Rt. (conc.) 1. Lt. 5.	Rt. pelvis well visualised. Lt. not seen.	Some abnor- mality at upper calyces.	Rt. 60%. Lt. 35%.	Killed Sept. 18.	Lt. kidney shows destruction of tubules at upper pole. Blood-supply (carmine-gelatin) deficient here. Blood-vessels on rt. side well filled; better than on lt. (Fig. 5).
29	Dec. 20, 1934. Rt., Lowsley's technique.	Both 14.	(1) Rt. 12. Lt. 7. (2) Rt. nil. Lt. (conc.) 10.	—	Rt. pelvis deformed.	Both 15%.	Killed Mar. 21, 1935.	Rt. kidney small, scarred, and adherent to liver section. Destruction of cortex and pyelitis.
37	Jan. 22, 1935. Rt., Lowsley's technique.	Both 12.	Rt. 20. Lt. (conc.) 5.	—	—	—	Died May 6.	Lumbar sinus present and palpable lump in kidney region. P.M. Rt. pyonephrosis.
30	Dec. 28, 1934. Lt., Lowsley's technique.	Both 2½.	Rt. (conc.) 2½. Lt. nil.	—	Lt. hydro- nephrosis.	—	Killed Mar. 28, 1935.	Lt. kidney small. Section shows areas of dilatation of tubules as in hydro-nephrosis and some areas of fibrosis and some pyelitis.
35	Jan. 15, 1935. Rt., Lowsley's technique.	Both 15.	—	—	No definite abnor- mality.	Rt. 5 and delayed. Lt. 35 imme- diate.	Killed. Apr. 23.	Rt. kidney half size of lt., scarred and adherent to liver but on section there is plenty of normal looking tissue left.
36	Jan. 15, 1935. Lt., Lowsley's technique.	Failure.	Failure.	—	—	Rt. 10. Lt. nil.	Killed May 2.	Lt. kidney small, scarred, and section shows extensive destruction of tubules with deficient blood-supply as demonstrated by Berlin blue injection into aorta.
39	Jan. 29, 1935. Rt., Lowsley's technique.	Both 17.	Rt. nil. Lt. (conc.) 3.	—	—	—	Died May 9.	Rt. kidney almost complete destruction of cortex with a marked calcium deposit. Pyelitis present.

P.S.P. = phenolsulphone-phthalein.

Two had hydronephrosis; 2 complete atrophy; 6 marked diminution in size and deformity to the naked eye; 2 changes slight.

As a matter of interest it may be worth recording that one other dog developed renal calculi. This animal had had a preliminary nephrectomy and then, after an interval, hemisection of the remaining kidney. At cystoscopy a month later this kidney excreted a concentrated dye, but after another month the animal suddenly died. Post mortem the kidney, though small, looked otherwise normal, but on opening it many calculi were found in the pelvis.

Histological Examination.—The general findings were areas of tubular destruction, most conspicuous in the cortex. These were probably related to areas of deficient blood-supply. In order to investigate this point carmine-gelatin was injected into the aorta while the animals were still alive, since it was felt that this method would not give results

FIG. 1.—Kidneys of Dog 16 showing partial atrophy of right kidney.

of much significance after the circulation had stopped. The carmine was blown in under constant pressure and then the circulation released as quickly as possible before the animal died. Four rabbits treated in the same way (hemisection of kidneys) were given injections of intravital trypan-blue several days prior to the carmine injection, and in this way a combined picture of the tubular function and the blood-supply was obtained. These sections show an intense blue in the tubules of the sound side, whereas on the operated side there is considerable deficiency of blue in the tubules where these are damaged, and here the carmine shows defective blood-supply. These appearances are interpreted as meaning that the function of the sound kidney has increased to counter-balance the damage done to the other side.

FIG. 2 (Dog 17).—Retrograde pyelogram showing partial atrophy of right kidney.

FIG. 3 (Dog 17).—Destruction of tubules on right side (B); hypertrophy of tubules on left (A).

SUMMARY AND CONCLUSIONS

Among 12 dogs on which hemisection of a kidney was performed there were 4 deaths; and 1 other animal showed atrophy of the kidney. Of the remaining 7, 2 can be passed as normal, while 5 had greater or lesser degrees of injury. Observation over three months suggested that the damage was not progressive, although the sound kidney was doing extra work.

It seems clear from this investigation that in assessing the anatomical and physiological condition of the kidneys too much reliance should not be placed on the usual tests of renal function as carried out clinically. Conclusions must be based for the most part on the naked-eye, and to a less extent the microscopic, appearance of the kidneys. In considering the question whether hemisection is

FIG. 4 (Dog 18).—Hydronephrosis of right kidney.

FIG. 5 (Dog 20).—Carmine-gelatin injection five months after operation. Increased blood-supply in right kidney (B); decreased blood-supply in left.

worth while, it must be remembered that it falls into the category of exploratory operations. A sine qua non of such an operation is that it shall do little harm to the organ explored, and hemisection receives no justification from experiments in which the kidney was severely damaged in 4 cases out of 12 cases, and largely atrophied in another.

Nor does it seem that Lowsley's technique is noticeably less deleterious in its effects than the ordinary operation in which mattress sutures are used.

I am indebted to Dr. F. T. Ranson for suggesting the investigation, to Mr. R. V. Dent for the photographs, and to Mr. Henderson for the sections, and to Messrs. Davis and Geck Inc. for a supply of ribbon catgut.

Clinical and Laboratory Notes

PERFORATED GASTRIC ULCER

RECOVERY IN A MAN AGED 81

BY T. ST. M. NORRIS, M.B. Camb.,
 M.R.C.P. Lond., D.P.H.

SENIOR ASSISTANT MEDICAL OFFICER, THE ARCHWAY
 HOSPITAL (L.C.C.), LONDON, N.

RECOVERY after perforated gastric or duodenal ulcer appears to be rare in the aged. Schulein¹ describes two cases in which a man and a woman, both aged 76, died after operation. Speck² records one case of a woman aged 69 who survived for eight weeks after operation and then died of heart failure; he also gives statistics of eight others all over the age of 60, but does not mention their fate. Graves³ describing eight cases between the ages of 60 and 70 had a recovery in three of them; while Gilmour and Saint,⁴ in a series of sixty-four cases, give the age of five as over 60, the oldest male being 67 and the oldest female 69; only three of the sixty-four failed to recover. Read,⁵ Brown,⁶ and Scotson⁷ also give statistics of perforation in patients over the age of 60, but they do not give information about the fate of individual patients.

The case I describe seems worthy of record in view of the patient's age and his uninterrupted recovery.

On admission to the Archway Hospital the patient gave a history of dyspepsia for the past two years, but he had been comparatively well until the morning of his admission to hospital, when he had suddenly collapsed with severe abdominal pain while engaged in sweeping out his room; he had not vomited. He was an elderly man with severe arterio-sclerosis. The pulse-rate was 116 and the temperature 99.2° F.; although obviously in considerable pain he was not severely collapsed and was able to give a clear account of himself. The abdomen moved very little with respiration; it was rigid throughout, and there was no liver dullness.

The operation under general anaesthesia was begun nine hours after perforation. The peritoneal cavity was found to contain gas and free fluid, and there was a perforation in the anterior surface of the stomach near the pylorus. This was closed with interrupted stitches and reinforced with a piece of adjacent omentum. The

pouch of Douglas was drained by a tube through a supra-pubic stab wound. The patient's convalescence was uneventful and the wound healed by first intention. On discharge home 25 days after operation the scar was sound and the patient walked well. When seen again six months later he stated that he had rapidly gained strength; he now looked after himself and frequently walked 3-5 miles daily; he had no dyspepsia or inconvenience and eats a light mixed diet.

The radiologist's report on a barium meal reads: "The stomach showed normal appearance except for some irregularity on its lesser curve near the pylorus. The latter functioned well, and on pressure the duodenal cap could be well filled; no ulcer crater could be demonstrated either in the stomach or the duodenum."

A reference to the records of Somerset House confirms the age of the patient as 81.

My thanks are due to Dr. C. D. Agassiz, medical superintendent of the hospital, for permission to publish this case, and to Dr. F. G. Nicholas for his report on the barium meal.

POLYSEROSITIS

BY O. K. G. GUYER, M.D. Edin.
 AND

F. B. SMITH, M.D. Camb.

PATHOLOGIST TO THE ROYAL INFIRMARY, PRESTON

THE subject of polyserositis is complicated by the confusion and complexity of nomenclature; several conditions clinically similar are included under the same title. The term seems most suitable to describe a chronic hyperplastic serositis of the pleural, peritoneal, and, sometimes, pericardial cavities. Some of the synonyms are multiple serositis, Concato's disease, Pick's disease (pericarditic pseudocirrhosis of the liver), diffuse chronic hyperplastic perihepatitis, chronic hyaline perihepatitis, chronic proliferative peritonitis, and Zuckergussleber of Curschmann.

Adherent pericarditis of known aetiology may end with heart failure, chronic venous congestion of the liver, oedema of the lungs, pleural effusion, and ascites, and yet be known by any of the above names, particularly Pick's disease. It does not, however, show the widespread, uniform picture of serous hyperplasia and polyserositis described below, though it is not unusual to find sugar-icing of the liver, peritoneum, and pleura in a minor degree. Chronic nephritis, particularly if associated with arterio-sclerosis or alcoholism, may cause or be associated with Zucker-gussleber, and pearly spots on the pericardium; but the fibrosis never approximates to that met with in polyserositis.

Polyserositis appears to be distinct from "adherent pericarditis" of rheumatic, tuberculous, or pyogenic origin. Its association with chronic nephritis or alcoholism may be fortuitous or causative, the aetiology of both being unknown. In the case described this association was absent.

Polyserositis is an essentially chronic disorder of the middle and later periods of life, whereas pericarditis is usually seen in young people. The symptoms are insidious—namely: (1) Abdominal

pain, due to involvement of peritoneum. (2) Recurrent effusions into serous cavities, requiring more frequent tapping than those of simple cirrhosis of the liver or less virulent forms of pleurisy. (3) Obstruction of the great veins of the trunk with œdema of the limbs. Despite these symptoms the patient's condition may remain good for as long as five or ten years. (4) There is also apparent glandular enlargement in axillæ and groins, due to embedding of lymphatic nodes in active fibrosis of connective tissue.

Radiography may help in deciding that the heart is fixed, the normal movement being replaced by an up-and-down motion; the cardiac enlargement distinctive of pericarditis may be absent in polyserositis. The electrocardiogram may show fixation of axis, due to partial or complete immobilisation of the heart.

The fluid obtained from the pleural cavities is usually clear, yellow, cell-free, and sterile, and contains 3 per cent. of albumin; the ascitic fluid has occasionally been described as chylous.

The fibrosis may be greater on the right side of the body, possibly because there are more lymphatic channels through the right cupola of the diaphragm than through the left. Death results from slow constriction of lungs, heart, and great vessels.

CASE-HISTORY

In 1929 a man, aged 38, sustained an "injury" to the sacro-iliac region while at work. There were no radiographic signs, but he was thenceforward unable to work and was given weekly compensation. In November, 1933, he was in hospital with pain in back; "loss of use" and swelling of legs; cough, six months; sense of constriction in throat. He discharged himself after three days, but in December, 1933, was admitted to another hospital.

Complaint: pain right chest and pit of stomach, especially after food; dyspnoea; swelling of legs; cough.

Physical state: cyanosis; distended chest veins; solid middle and lower lobes right lung; right clear pleural effusion; fixed, firm glands in axillæ and femoral triangles; much frothy sputum; heart displaced to left; pulse-rate 120; afebrile; ascites absent; tender liver; Wassermann reaction negative; no anæmia; 13,600 total leucocytes per c.mm., 11,600 (84 per cent.) being neutrophils; X ray? neoplasm right lung.

Diagnosis: neoplasm right lung.

After discharge the right pleura was tapped every two or three weeks. Accidental pneumothorax occurred once and appeared to give relief and postpone the next tapping.

FIG. 3.—Subpleural fatty connective tissue; vascularised and permeated by lymphoid and plasma cells. ($\times 200$.)

FIG. 4.—Hepatic peritoneum. Portion of acute inflammatory focus; polynuclear leucocytes numerous. ($\times 200$.)

There was increase of hepatic pain and tenderness, with œdema of adjacent anterior abdominal wall; more frequent acute epigastric pain and vomiting, only relieved by morphia, and slight ascites. In October, 1934, he was readmitted to hospital. There was loss of weight; tense abdomen, with slight ascites; slight pleural effusion and pneumothorax; 70 per cent. hæmoglobin, 9200 neutrophils per c.mm.; liver enlarged downwards and tender; signs of cardiac hypertrophy and dilatation absent. An inguinal gland was excised for examination. The patient discharged himself after one week, and in November, 1934, at the age of 43, he died by sudden failure of right side of heart.

NECROPSY

General.—Pale; moderate wasting; upper abdomen prominent and tense; chest assymetrical, left side more prominent anteriorly than right; varicose distension of superficial veins of neck and upper half of chest; diffuse swellings, apparently glandular, in both groins and both axillæ.

Thorax.—Back of sternum only detached from pericardium and mediastinum by cutting dense, white, rather elastic tissue, which spreads laterally over anterior borders and surfaces of both lungs. Large, slightly hæmorrhagic pleural effusions (bilateral). Left lung compressed by pleural effusion; substance œdematous and congested; lung free except on medial aspect, where the pleura fuses with general mediastinal mass of dense, white tissue; lateral and posterior left pleura normal. Right pleural sac partly obliterated by loculi of yellow, gelatinous exudate; right lung much collapsed, encased in dense coat of "sugar ice," with pitted surface, and 2 to 7 mm. thick; upper lobe removed by incision through large areas of fusion of visceral and parietal pleura; right parietal pleura, where free, is 5 to 8 mm. thick; this sclerosis penetrates upper intercostal spaces on both sides, infiltrates the axillary spaces and embeds groups of lymphatic glands of normal appearance; sclerosis lacks defined limits and resembles mediastinal tissue. Anterior part of pericardium thick and adherent to back of sternum and anterior surface of heart. Heart distorted by antero-posterior compression, showing atrophy of muscle and marked dilatation of right side.

Abdomen.—White, dense sclerosis covers both surfaces of both sides of the diaphragm, upper surface of liver, left perirenal tissue, and whole of prevertebral tissue, so that a solid mass embeds aorta, inferior vena cava, duodenum, and pelvic portions of ileum and colon. In front of the spine this mass is 20 to 30 mm. thick. Lower border of liver is at level of umbilicus; left lobe adherent to anterior

FIG. 1.—Fibrosis encroaching on inguinal gland. Very cellular, vascular, and of active growth. ($\times 100$.)

FIG. 2.—Pleura. Features similar to Fig. 1. ($\times 100$.)

abdominal wall; liver weighs 1.9 kg. (plus 20 per cent.). Spleen adherent to stomach and diaphragm. Sclerosis involves both iliac sets of main vessels, penetrates to the femoral triangles where lymphatic glands are embedded, as in axillae. Lateral peritoneum of the pelvis is very thick, burying the nerve-roots to the lower limbs. Skull and spinal column, central nervous system, and remaining viscera normal.

Microscopical.—Rather than hyaline lamination, the features of the fibrosis are cellularity, vascularity, and active growth, suggesting active infection, though micro-organisms could not be demonstrated in sections. The penetration of the fibrosis to the axillary and inguinal spaces appears unrecorded in the literature.

Polyserositis should be considered, therefore, in the presence of any or all of the following symptoms: mediastinal or abdominal venous obstruction, recurrent effusion into serous cavities, adherent pericardium, and enlargement of the liver—even if these are associated with apparent glandular enlargement. In the case described the pericardial lesion was an embedding of the heart and great vessels rather than adhesion between the parietal and visceral pericardium. Thus it follows that polyserositis should be considered as an alternative diagnosis to mediastinal neoplasm, Hodgkin's disease, adherent pericarditis, and cirrhosis of the liver.

We wish to thank Dr. A. E. Rayner for his permission to record this case which was under his charge, and Mr. H. C. Taylor for the photomicrographs.

HISTAMINE IONISATION IN RHEUMATISM AND ALLIED CONDITIONS

ANALYSIS OF ONE HUNDRED CASES

By F. SEVERNE MACKENNA, M.B. Dub.

HON. PHYSICIAN TO THE ROYAL BRINE BATHS CLINIC AND
PHYSICIAN TO THE HIGHFIELD HOSPITAL FOR
RHEUMATISM, DROITWICH

ALTHOUGH the series of consecutive cases reviewed here is somewhat short, an analysis of the results may be of value in showing how histamine can be used in the routine treatment of rheumatism. The total number of applications was 2496—an average of 25 per patient—and it was usually found that at least 12 were required for any permanent improvement. Apart from an insignificant number who were found to be constitutionally unsuited for balneological treatment, all the patients received concurrently some form of brine bath, and often massage in addition.

The method of treatment employed is essentially the same as that already described,¹ with the notable addition of a preliminary preparation of the area with multiple punctures and scratches produced by a special scarifier. This procedure is based on that recommended by Vas,² and is now finally considered beneficial. In most cases the histamine was given daily and it is considered important that baths or

other additional treatment should follow and not precede its administration.

In the accompanying Table the various groups have not been subdivided and the nomenclature is based on the recommendations of the Arthritis Committee.

Clinical Analysis

	Males.	Females.	Total.	Cured.	Greatly improved.	Improved.	No change.	Worse.
Fibrositis	18	29	47	7	27	11	—	2
Neuritis	6	4	10	—	1	2	—	—
Osteo-arthritis ..	9	4	13	—	—	9	4	—
Rheumatic arthritis ..	1	2	3	—	—	1	2	—
Villous arthritis ..	3	20	23	—	14	—	—	1
Spondylitis	2	—	2	—	—	—	—	—
Traumatic arthritis ..	2	—	2	2	—	—	—	—

In this Table only the disabled parts that received treatment are considered: where there was a mixed condition the remaining disabilities are ignored.

NON-ARTICULAR CONDITIONS

Fibrositis.—The majority in this group had lumbar and shoulder-girdle fibrositis. Of the 47 cases, 7 were passed as clinically cured; all except one showed very great or great improvement, and in most of them it was believed that sufficient treatment would have completely removed the disability. The greater number had massage in addition to baths. The two cases which are reported as worse were complicated by an erratic "psyche" which precluded the possibility of relief from any ailment, and treatment was not persevered with.

Neuritis.—In this group are included cases of root and trunk sciatica, and brachial neuralgia. Of the 10 patients treated, 7 were discharged and have remained free from pain. Improvement was unsteady in all and there were occasional recrudescences, each less severe than the one before. One fell short of complete recovery because the patient persisted in taking forbidden exercise.

CHRONIC JOINT CHANGES

Osteo-arthritis.—Of the 13 cases, 9 showed improvement; 6 of these were of the hip, 2 of the knee, and 1 of the shoulder-joint. There was a steady lessening of pain and usually an increase of movement after the first application. Of 4 patients that returned only 1 had become worse in the interval (seven months). In 4 the improvement lasted only a few hours.

Rheumatoid Arthritis.—Only 3 patients were treated, and of these 1 alone showed definite improvement.

Villous Arthritis.—The knee was affected in each of the 23 cases, and there was almost always a very gratifying result, with loss of pain and greatly increased movement. Massage was given in every case. In this group again 1 patient failed to respond or persevere.

Spondylitis.—The 2 cases treated were both of the osteo-arthritic type, the patients being men of 35 and 38. There was much improvement in posture, with a great lessening of pain, and this progress had continued in one of the patients who returned after 3½ months for a second course. Plaster shells were fitted for night use, and baths and massage were also given.

TRAUMATIC CONDITIONS

Both the patients in this group had "badminton elbow" and recovered rapidly and uneventfully with

¹ Mackenna, F. S.: THE LANCET, 1934, i., 1228.

² Vas, S.: Deut. med. Woch., 1932, lviii., 1009.

five and seven administrations each. No other forms of treatment were used.

COMPLICATIONS AND INTERCURRENT DISEASE

Collapse.—There were three cases in which histamine treatment caused collapse.

CASE 1.—Female, aged 49. Fibrositis. Menopause at present; extremely neurotic. This patient did moderately well until the seventh treatment, but suddenly collapsed about a minute after beginning the eighth; the pulse disappeared at the wrist and there was slight vomiting. She gradually recovered after some hours, but had hysterical prostration afterwards. No remedy beyond the ordinary was employed.

CASE 2.—Female, aged 68. Sciatica and fibrositis. She was very neurotic and began to show signs of collapse after the third treatment, on the appearance of the facial flush. Ephedrine (1 c.cm.) was injected, with rapid improvement and complete recovery in about eight minutes. Subsequently five more treatments were successfully given and there was considerable improvement, but the patient became more "nervy," refused all treatment, and departed.

CASE 3.—Female, aged 73. Fibrositis and brachial neuralgia. This woman was very sensible and vigorous, and a first course of 42 treatments resulted in complete cure of the neuralgia and an improvement in the old-standing lumbar and gluteal fibrositis. A second course was started five months later but at the third treatment there was a dramatic and severe collapse. Rapid relief was obtained from ephedrine, and the patient afterwards declared that she felt better than for many years and that all the backache had gone. Further treatment was given to the lumbar region and there has been no return of pain after eight months.

With the exception of hysteria, which was conspicuously absent in the third patient, there was nothing remarkable about any of these cases, nor was the collapse due to an overdose in the usual sense. The onset of symptoms was sudden and not preceded by any visible signs, nor did the patient notice anything unusual. The most careful inquiry subsequently into diet, &c., failed to produce a solution. The collapse presumably bears some relation to the (so far unexplained) variation in histamine tolerance shown by each patient from day to day. Ephedrine appears to be an efficient antidote.

Intercurrent Diseases.—In 5 cases the systolic pressure was over 200 mm. Hg, and showed not only the customary post-histamine fall of several millimetres noted by Bisset and Woodmansey,³ and Shanson and Eastwood,⁴ but also a definite downward tendency throughout the course. This was, however, never greater than a total of 15 mm. Two cases of chronic asthma and bronchitis were included and appeared to be unaffected either temporarily or permanently by the drug; in other respects they progressed normally. Gross valvular and myocardial lesions were rejected, but those with less advanced disease that were suitable for bath treatment were accepted and took the histamine successfully.

CONCLUSIONS

It is to be regretted, for the purposes of this analysis, that other forms of treatment could not be excluded, but it is noteworthy that many patients who have taken a course of baths for several years are emphatic in their statements that histamine has greatly increased the benefit received; undoubtedly it also increases the rate of recovery. It may be said to fail in cases of the rheumatoid type, where the joints are swollen and "doughy" and the skin

clammy, but in all others, and particularly in villous arthritis, fibrositis, and neuritis, its value is unquestionable.

NON-TRAUMATIC SURGICAL EMPHYSEMA

IN ASSOCIATION WITH ACTIVE PHTHISIS

BY DAVID N. DOBBIE, M.B. Edin.

RESIDENT MEDICAL OFFICER, BIRKENHEAD MUNICIPAL HOSPITAL

SURGICAL emphysema occurring in a phthisical patient is usually superficial and due to faulty artificial pneumothorax technique. Interstitial emphysema, though it is not a very uncommon complication of broncho-pneumonia and whooping-cough, is rarely met with in pulmonary tuberculosis, presumably because of the fibrotic changes taking place in advance of the active lesion. When it does occur it generally follows an unusually severe bout of coughing which ruptures an alveolus and allows air to escape into the interstitial tissue of the lung, and so, by way of the hilum, to the mediastinum. From here the air passes to the subcutaneous tissue of the neck, face, and chest, thus establishing a "surgical" emphysema. This condition is believed to be rare enough to warrant the publication of the following case.

A man, aged 26, was admitted to Birkenhead Municipal Hospital on Nov. 12th, 1935, having a history of chest trouble of at least six years' standing. He was extremely emaciated and complained of asthenia and cough; the temperature was remittent, and sweating was profuse. Clinical examination revealed scattered patches of consolidation in both lungs, with fairly extensive cavitation at the right apex. Tubercle bacilli were present in the sputum.

No improvement took place during the next five weeks; emaciation became more obvious, and the cough assumed a paroxysmal character. On Dec. 19th, at 10.30 A.M., the patient complained of slight dysphagia and a bilateral swelling of the neck was noticed. By midday the neck had become increasingly swollen and crepitus was elicited on pressure. The superficial tissues of the chest wall and lower jaw became involved, and on the following day the face, particularly on the left side, was greatly swollen and disfigured, with massive involvement of the tissue of the lower eyelids. The patient was very dyspnoeic and becoming cyanosed. Sweating was profuse. On Dec. 21st the surgical emphysema had spread to the anterior abdominal wall and flanks, and was encroaching on the lower limbs. Breathing now became exceedingly embarrassed and death took place at 8.20 P.M., 58 hours after the onset of the acute symptoms.

On post-mortem examination both lungs were found to be studded with tuberculous foci with considerable cavity formation. No collapse was present on either side. The mediastinal tissues were ballooned up with air, and this could be traced to the subcutaneous tissues behind the clavicles.

There was no history in this case of artificially induced pneumothorax, nor did the post-mortem examination reveal any evidence of spontaneous pneumothorax.

I wish to thank Dr. R. A. Grant, medical superintendent, for permission to publish these notes.

ROYAL MASONIC HOSPITAL, LONDON.—The figures for this hospital for the last half of 1935 show an excess of expenditure over income of £7141, against £9425 in 1934, although the patients resident on daily average have been 125 against 113. Lord Marshall, in submitting the treasurer's report at the annual general meeting on Jan. 29th, stated that when the nurses' home was complete and ready for occupation the average costs would be further reduced and the position considerably improved.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF SURGERY

At a meeting of this section on Feb. 5th, with Mr. SAMPSON HANDLEY, the president, in the chair, a discussion on

Sterilised Surgical Catgut

was opened by Sir WELDON DALRYMPLE-CHAMPNEYS. He said that the occurrence recently in rather rapid succession of a number of cases of post-operative tetanus, either certainly or probably due to the use of what might be termed "home-cured" catgut, made it important to emphasise the dangers of inefficiently sterilised material; though control under the Therapeutic Substances Act had raised the general standard of sterility of surgical catgut on sale in this country. The raw material from which catgut was prepared was the small intestine of the lamb, and was heavily infected with micro-organisms of many kinds, including pathogenic spore-bearing anaerobes. On reaching the manufacturer the raw material was either thawed out (if frozen) or washed free from salt (if this had been used as a preservative) or, if dried, soaked in dilute alkali to make it soft and pliable. Even if not dried it usually received this soaking. The gut was next split into ribbons longitudinally and then scraped to remove the inner and outer layers, leaving only the submucosa. The ribbons were measured and spun, two or more ribbons being twisted together to form a string. The gauge of the finished gut depended on the number of ribbons spun together. Sometimes the ribbons were partially sterilised before spinning by soaking in disinfectant solution. The strings were dried under tension and polished with pumice or emery, and then graded by measuring their calibre with a gauge. It was important that the gauge of any individual string should vary only very slightly at different points in its length. If hard slowly absorbed gut was required the strings at this stage were immersed in a chrome bath. Gut partially sterilised before spinning was often sold as "internally sterile" or "partially sterilised" catgut and, as it was not called "sterilised surgical catgut," did not come under the control of the Therapeutic Substances Act. Purchasers of such catgut were apt to assume that the product required less sterilisation than raw catgut, and some of the wound infections following the employment of catgut sterilised by hospitals for their own use were, he believed, attributable to this erroneous assumption.

Heat was the most reliable sterilising agent, provided the physical properties of the gut could be preserved unimpaired. The heating of catgut rapidly in air to a temperature sufficient to destroy anaerobic spores, if it did not actually burn it, rendered the gut as hard as wire and extremely brittle. Methods had been devised for overcoming this difficulty, and some had proved completely successful, but there was a temptation to reduce the temperature or time of heating below the safety point if the tensile strength of the gut was found to be unsatisfactory. Iodine had been used for sterilisation of catgut because of its penetrating power. Owing to its colour, the degree of penetration of iodine could be verified by examining a cross-section of the gut. Excess of iodine must be removed at the end of the process because prolonged action rotted the gut, reducing

its tensile strength. The value of mercurial salts for sterilisation of catgut had been overrated; they were bacteriostatic only, though they had some disinfectant action on the exterior of the gut. Hydrogen peroxide was an efficient sterilising agent, but as it caused spun gut to swell it was never used alone, but employed for treating the wet gut as a preliminary to the action of iodine. Essential oils had a negligible action on spore-bearing bacteria, and it was difficult to account for their popularity among hospitals sterilising their own gut.

After sterilisation, the gut was introduced into containers, together with a filling solution. The principal types of container were sealed glass tubes; glass tubes closed with a rubber cork and metal screw cap; similar tubes containing several reels of gut, the ends of which were drawn out through side tubes, closed in the manner described; waxed cardboard cartons; and finally multiple sealed paper envelopes each containing a single coil of dry gut. Any packing which allowed repeated extractions of portions of gut from the same container must be regarded as highly unsatisfactory. Filling solutions should only be regarded as useful for killing organisms on the *outside* of the gut which had got there during packing. Tubes were sealed in the ordinary way in the flame of a blowpipe.

Catgut might become recontaminated:

(1) By handling before it was put into the container. Sterilisation inside the container was therefore desirable.

(2) By air-borne organisms, from dust or the breath of operatives, entering the container before sealing. This source of contamination might be avoided by the use of metal boxes with sliding lids to hold the containers, rubber gloves, face masks, and a glass shield over the sealing table.

(3) By the use of unsterile containers.

(4) By the use of unsterile stoppers in the interval between filling and sealing.

(5) By the use of unsterile filling solutions. Even solutions containing so-called antiseptics might provide such a source of contamination if they were incapable of killing the spores of anaerobes.

The examination of a reasonable length of any batch of catgut by sterility tests could not ensure that the whole of the batch was sterile. A licensee under the Act was required to carry out sterility tests on not less than 1 per cent. of the material constituting a batch. The control tests carried out by the licensing authority were identical with those which the licensee was required to perform as a routine.

In February, 1933, Dr. R. O. Clock, of New York, had published the results of bacteriological examinations of gut sterilised by different methods. He had concluded that "heat sterilisation properly controlled was the only safe and positive method for sterilising surgical catgut sutures." In a further paper published in December, 1934, he had given results of the examination of 1204 sutures emanating from Great Britain, France, Germany, Japan, and Spain, and had found that 4 of the 8 British brands, 1 of the 4 French brands, 5 of the 6 German brands, 2 of the 4 Spanish brands, and both of the 2 Japanese brands were non-sterile. His tests, however, were tests of *absolute* sterility and could hardly be regarded as practical for everyday control. Prof. T. J. Mackie, of Edinburgh, had found that ethyl alcohol, oil of cloves, oil of eucalyptus, phenol, and lysol had little action on bacterial spores. Formalin was more effective but

acriflavine and crystal-violet brilliant-green mixture were ineffective, and biniodide of mercury failed to kill spores after they had been exposed for 82 days to a 1:1000 alcoholic solution. He had confirmed Bulloch's unfavourable report on perchloride of mercury. Silver nitrate had proved lethal to spores, and so had boric acid, but both tended to damage the physical properties of the gut; the same applied to iodine trichloride. He had found iodine water to be effective, again confirming Bulloch's earlier findings. A combined hydrogen peroxide and iodine water method gave a sterile gut with good physical properties. Little was known about the factors which governed the fate of catgut in the living body, but Dr. V. D. Allison's recent work had shown extreme variation in resistance to tryptic digestion in vitro of commercial catgut. Mackie had reached the following conclusions in regard to the presence of *Bacillus tetani* in catgut: (1) the presence of the bacillus in the raw material was irregular and variable; (2) only certain batches of any commercially sterilised catgut might be contaminated; (3) bactericidal processes, even if not entirely effective, might destroy the majority of the spores; (4) survivors might be scanty and irregular in distribution; (5) the thickness and amount of catgut left in the tissues might determine the multiplication of the bacillus; (6) other factors might be involved, including perhaps factors affecting the power of spores to germinate in the tissues.

Certain cases of post-operative tetanus had lately come to the notice of the Ministry, one group from a hospital in the north and another group from a hospital in the south. In the northern group, two cases had followed operations for inguinal hernia, and the patients had recovered; the third, following nephrectomy, had proved fatal. The catgut used was bought raw and sterilised at the hospital by boiling in xylol for half an hour and then storing in spirit. Samples of gut similar to that used at the operations were examined and found to be heavily infected with aerobes and spore-bearing anaerobes, but *B. tetani* was not demonstrated. Some of the dry catgut before sterilisation, however, was found to contain the bacillus. Four cases occurred in the southern group, of which two ended in recovery and two were fatal. Both commercially sterilised catgut and catgut sterilised at the hospital were in use here, but the theatre sister thought it probable that hospital-sterilised gut had been used in the second fatal case, and might well have been used in the others. The method of sterilisation employed was immersion of the gut in oil of cloves for 14 days followed by storage in absolute alcohol for 8 days. Post-mortem material from the second fatal case and specimens of both kinds of catgut were examined, but *B. tetani* could be isolated only from the appendix stump. The tetanus spores might have been present in the patient's intestine and have infected the appendix stump, or she might have acquired her infection from the catgut. It was unlikely, however, that *B. tetani* was present in the bowel of all four of the cases affected, and moreover in two of them the bowel had not been interfered with at operation. The method of sterilisation employed at the hospital had been shown experimentally to be ineffective in killing tetanus spores, and altogether, although proof was lacking, the evidence indicated the conclusion that the infection came from the "home-cured" catgut. He appealed to surgeons to inquire into the methods employed for the sterilisation of the catgut they used at operation.

DISCUSSION

Prof. W. BULLOCH said that biniodide of mercury was perfectly useless. He had infected small hanks of sterilised silk ligatures with *Bacillus ruber* and had placed them in a solution of 1 per cent. biniodide. He had tested this material 40 times over a period of ten years and had obtained a pure culture of the bacilli on every occasion; what they lived on he could not say. He thought there were only two methods of sterilising catgut effectively: either by immersion in iodine solution for eight days or by heat. He believed that tetanus in catgut was a bogey. In 17,420 samples of catgut which he had examined he had never once found tetanus.

Prof. JAMES MCINTOSH said that all surgeons had encountered cases of post-operative tetanus. Tetanus bacilli could be isolated from the wound in such cases; in the last one he had examined, however, no tetanus had been obtained from the wound, but the wood-wool used to pack the splint had been found to be heavily infected with the organism. He thought we had yet to go a long way to prove that catgut was a source of post-operative tetanus infection.

Prof. PAUL FILDEN agreed that if too much attention was directed to catgut surgeons might overlook other important sources of tetanic infection. In his work he was often called upon to find the tetanus bacillus in sites where it was present—and he did find them; if he failed to find them elsewhere, therefore, it might count, he thought, as useful evidence that they were absent. And though he had found the bacillus in every one of 40 cases of tetanus he had never once found it in surgical catgut. He described a case of pyonephrosis in which excision of the kidney was followed by tetanus; the wound at post-mortem was swarming with tetanus bacilli, but though he examined 50 reels of catgut of the same brand as that used at the operation he had found no tetanus. In another case the knee-joint was excised for tuberculosis and the leg put up in a plaster splint. Three months later the patient developed tetanus and died. The whole operation area was excised and cultured but no tetanus bacilli were grown; but in the wood-wool used as dressing tetanus spores were found. He was convinced the infection of some slight abrasion from the dressing was responsible for the symptoms. He thought that more cases of post-operative tetanus occurred than were reported, and he hoped that every surgeon who encountered a case would put the facts on record so that they could be properly sifted.

Dr. JOHN BEATTIE said that the impregnation of catgut with silver salts gave a sterile gut with sufficient tensile strength for surgical purposes. This method might, it has been suggested, act merely by encasing the spores in silver, but if they were effectively imprisoned it did not matter whether they were living or not. The smaller hospitals often used unsuitable methods of sterilisation, and these must be replaced by a good method which was both simple and cheap. They could not all afford catgut which was sterilised under rigid conditions. He thought that tetanus in catgut was a bogey only as far as the London Hospital was concerned. Post-operative tetanus and wound infections due to catgut were much commoner at hospitals where catgut was not prepared so efficiently.

Dr. V. D. ALLISON said that he had been using trypsin to digest and soften catgut so that any organisms embedded in it might be induced to grow. He had found catgut digested in this way to be teeming with organisms—staphylococci, streptococci, spores, and vibrios, mostly dead. He had also tried

injecting extracts of catgut into animals and had once got tetanus from a sample of catgut requiring to be sterilised before use, but never from catgut declared to be ready for surgical use. A substitute for catgut was most desirable and a new material made from horseflesh was stated to be sterile, flexible, readily absorbed, and of good tensile strength. It was time new experiments were carried out to decide how long different catgut ligatures took to absorb. The rates of digestion with trypsin were very variable.

Lord HORDER remarked that the bacteriologists did not seem to confirm the responsibility of catgut for post-operative tetanus. Might the same arguments apply to gas-gangrene? He would also like to know to what extent surgical technique was dependent on catgut as against other forms of ligature. Was absorbability the great virtue of catgut determining its use?

Mr. W. M. DICKIE said that three areas where outbreaks of post-operative tetanus had occurred were areas in which heavy grades of catgut were commonly used. Such grades were hard to sterilise and persisted for a long time in the tissues. If the lightest possible catgut was used there was less likelihood, he thought, of getting tetanus.

The CHAIRMAN said that he rarely used catgut unless he was forced. He found that unabsorbable sutures, provided they were thin enough and sterilised just before use, were rarely attended by the disadvantages usually attributed to them.

Mr. CARWARDINE urged all surgeons to prepare their own ligatures and handle them in person until the last minute. He had always sterilised his own catgut by the xylol method, and he had never seen any tetanus.

Sir WELDON, in replying, said that the thesis that tetanus in catgut was a bogey had not been proved. The discussion had shown the need for further research. He trembled to think what would happen if all surgeons prepared their own catgut; not all of them could be trusted to perform the task as carefully and successfully as Mr. Carwardine.

SECTION OF LARYNGOLOGY

A MEETING of this section was held on Feb. 7th, with Mr. LIONEL COLLEDGE, the president, in the chair.

Mr. MAXWELL ELLIS read a paper on the mechanism of the

Bronchial Movements and Naso-pulmonary Reflex

He said that his interest in the subject had first been aroused when he was working in Dr. Chevalier Jackson's bronchoscopic clinic and noticed the movements in the bronchi of certain asthmatics. This led him to an attempt at recording these movements. He briefly described the muscular structure of the bronchial tubes, and pointed out that the muscle extends as a continuous network from the trachea to the air sacs. The fibres run neither circularly nor longitudinally, but obliquely, in "geodesic" lines, as depicted by William Snow Miller, enclosing lozenge-shaped spaces. They end at the mouths of the atria, surrounding these openings almost in the manner of a sphincter. It had been deduced from the structure of the bronchi that they elongate with inspiration, shortening during expiration, but different opinions had been expressed about the nature of the alterations in calibre.

Mr. Ellis said that none of the experimental methods of measuring and recording these movements did this directly. The classical investigations of Dixon and Brodie in 1903 consisted in measuring the changes in volume of a lobe of a lung. By other methods the variations in intrapleural or intratracheal pressures were recorded. It was doubtful whether these measurements were reliable records of variation in intrabronchial capacity, particularly as the experimental animals were in an abnormal condition, and usually kept alive by artificial respiration. Mr. Ellis said that his method of recording changes in calibre in the larger bronchi of the dog was a direct one involving the use of the bronchoscope. A specially devised hollow instrument carrying a rubber balloon which could be inflated through a separate tube was inserted through a bronchoscope into the right bronchus. The balloon was loosely inflated and connected with a Brodie bellows capable of registering clearly changes in volume of one-tenth of a cubic centimetre. Respiratory exchange in the lung distal to the balloon was carried on through the lumen of the instrument and changes in calibre were thus directly recorded. Mr. Ellis showed tracings obtained in this manner, in one of which the bronchial contraction produced by pilocarpine and the relaxation produced by adrenaline were seen. He pointed out that synchronously with the respiratory movements are rhythmic alterations in calibre—inspiratory dilatation and expiratory narrowing—which had been commented upon by Fletcher Ingals and Chevalier Jackson some years ago as a result of their bronchoscopic observations, but not previously recorded by a direct method. The means of production of this rhythm was of interest: (1) it could be produced by impulses travelling in the vagi; (2) it could be an intrinsic property of the bronchial tubes, or (3) a mechanical effect of the respiratory movements of the thoracic walls. The first two hypotheses demand rhythmic contractions of smooth muscle at the rate of at least 15 a minute, and this behaviour of smooth muscle was not seen elsewhere in the body. He showed a tracing from a bronchus before and after bilateral vagotomy in which the bronchus narrowed to an even greater extent after it had been deprived of its constrictor nerve-supply than previously, which seemed to be evidence against the first hypothesis. In numerous experiments the bronchial movements had followed exactly the respiratory movements. Mr. Ellis thought that during the inspiratory phase of respiration the increase in thoracic volume tended to create a decrease in pressure in the lung substance, which in turn caused air to flow into the bronchial tubes, dilating them. The flexible structure of the tubes would permit of this. He considered that the network arrangement of fibres in the myoelastic layer explained how shortening and narrowing of the tubes go hand in hand during the expiratory-phase (decrease in lung volume). He believed that the maintenance of tone is the function of the bronchial muscle.

He went on to discuss the question of peristalsis in the bronchi. Yandell Henderson's work on the "dead space" and its occasional rhythmic variation was the best available evidence about this function and was supported by Lewis's demonstration of contraction waves in tissue-culture preparations of bronchial tubes from chick embryos. In his own experiments Mr. Ellis had never witnessed rhythmic relaxation followed by contraction which would indicate the possible existence of peristalsis, but he had occasionally observed variations in tone. For

a true demonstration of the phenomenon records from two fixed points in a bronchus were necessary, and these had not been obtained. A certain amount of work had been done on the influence on respiration of reflexes from the nose, but nothing convincing had been published on the effects of such reflexes on the bronchi. Mr. Ellis showed tracings of bronchial reactions produced by stimulation of the septum with a moderate faradic current and of the right nasal cavity with dilute ammonia vapour. Bronchial constriction occurred often but not invariably. Such stimuli were stronger than those which occur in normal life and might evoke pain and defence reflexes which obscured the picture; clear-cut results were not easy to obtain. This might perhaps be explained by the different functions of the canine and human nose. The principal function of the former was olfaction, and of the latter respiration, and the microscopic structure of the mucous membranes indicated this difference. The human nose might be more sensitive to stimuli, but he had had no opportunity of carrying out experiments on man and had no objective evidence to offer. On stimulating his own septum with an electric current, he received no subjective sensation of constriction in the chest, but he had no idea how much bronchial constriction was needed to convey such a sensation. He felt convinced, however, that the tone of the bronchial muscle could be influenced reflexly from the nasal mucous membrane, although he was not prepared to be dogmatic as to the precise mechanism. Finally, Mr. Ellis pointed out that it was essential to know more about the normal dynamics of the bronchi in order to understand the abnormal mechanics of asthma and other spasmodic respiratory diseases.

Dr. G. EWART MARTIN mentioned observations that he had made on patients during bronchoscopy. Blowing cold air down the bronchoscope resulted in a closure of the bronchus which relaxed on the introduction of warm air.

Mr. T. A. CLARKE asked whether Mr. Ellis had made any observations on the subject of homolateral reflexes between the nasal cavity and bronchial tree. He had read descriptions of such reflexes.

Mr. H. V. FORSTER mentioned that in some patients in whom the larynx had been excised movements of the diaphragm were unequal on the two sides. He wondered if this affected the lung by promoting unequal bronchial dilatation and, perhaps, lung expansion.

Mr. A. R. TWEEDIE recalled a case where the patient, during the performance of a nasal operation, suddenly went into an asphyxial spasm. He passed a bronchoscope and saw what appeared to be a complete closure of the secondary bronchi by swollen mucosa.

In reply, Mr. ELLIS said that theoretically he would expect the bronchial muscle to react to stimuli applied locally to the overlying mucous membrane. He had not yet investigated this aspect of reflex behaviour. He doubted the validity of the work quoted by Mr. Clarke. On theoretical grounds, as the sensory arc ended in the medulla, spread to both sides was almost inevitable, and both vagal nuclei would almost certainly be affected. He had on several occasions observed effects on the right bronchus resulting from stimulation of the left nasal cavity.

In the case quoted by Mr. Tweedie he thought an extreme form of bronchial muscle spasm had occurred. The bronchial mucous membrane contained no erectile tissue, and did not convey the impression

that it could suddenly swell several millimetres. He thought it likely that for some unknown reason the bronchial muscle in this patient was unusually irritable and was reflexly stimulated by the nasal operation to extreme tonic contraction.

A number of cases were exhibited and discussed at some length.

SECTION OF TROPICAL DISEASES AND PARASITOLOGY

At a meeting of this section on Feb. 6th, with Dr. P. MANSON-BAHR, the president, in the chair, Prof. R. T. LEIPER presented a demonstration on the

Crustacea as Helminth Intermediaries

This took the form mainly of lantern slides illustrating the life-histories of the dibothriocephalus tapeworms, the Guinea worm, and *Gnathostoma spinigerum*, all using species of cyclops as intermediate hosts, and the life-history of the lung fluke which uses certain fresh water crabs and crayfish as second intermediaries. He said that the life-history of the guinea worm had been correctly deduced, on the analogy of that of a very different worm in fish, from the close similarity of their embryos. *Gnathostoma spinigerum*, normally parasitic in the stomach wall of cats and dogs, had been found several times subcutaneously in man. The lung fluke, parasitising man and some other mammals in the Far East, and dogs in Venezuela, had recently been reported from a child in West Africa. It was very important that regional collections of crustacea should be made so as to ascertain the distribution of intermediaries, but in that connexion it had to be remembered that the entomostraca were also intermediaries for a number of helminths not parasitising man. Among these were several tapeworms of the same group as dibothriocephalus, some species of the four-suckered tapeworm genus *hymenolepis*, and many acanthocephala. Caution was therefore needed in interpreting the discovery of helminth larvæ in crustacea.

Dr. B. G. PETERS followed with a paper on some recent

Developments in Helminthology

which dealt with certain biological aspects of parasitism, mainly among the cestodes. Normal life-histories, he said, were occasionally departed from, as when larvæ of *Dibothriocephalus mansoni* or *Mesocoeloides*, fed to dogs, continued to live as larvæ in the peritoneum instead of becoming adults in the intestine. De Waele's work tended to show that tapeworm embryos and larvæ resisted intestinal digestion only because the surrounding egg-shell and cyst wall, respectively, protected them from the host's gastric juice. The adult cestodes appeared to have an anaerobic metabolism in which glycogen was decomposed to furnish energy, and fatty acids and carbon dioxide were excreted as metabolic products. So-called "age immunity" in helminths was a form of innate immunity. Acquired immunity could be most fully illustrated from Miller's numerous experiments on the larval stage of the cat tænia. These had revealed active immunity, both natural and artificially induced, and also passive immunity, both inherited and induced. Of immunological reactions employed in diagnosis, the Casoni skin test for hydatid was a group reaction among the tæniæ. Intradermal and precipitin reactions appeared to have been established as valuable methods for the diagnosis of trichinosis, both in man and in the pig.

Dr. N. HAMILTON FAIRLEY said that most helminthic immunological reactions were of a group nature, probably owing to the existing crude methods of preparing antigens. It was usually easier to detect fixed antibodies, as in skin tests, than free antibodies concerning which there was less knowledge.

Major-General W. P. MACARTHUR said that in cysticercosis the complement-fixation reaction varied in intensity along with eosinophilia; both were high in early stages, then tended to disappear, and finally to reappear with the death of the cysts.

In reply to a question whether, in view of the spread of the "mitten crab" in Europe, some local mollusc might not serve as first intermediary to the lung fluke in place of melania,

Prof. LEIPER said that he thought this unlikely. Trematodes were more specific as to first than as to second intermediaries. Moreover, both the lung fluke itself and the habit of eating raw crab would also have to be introduced before this parasite could spread in Europe.

MIDLAND OBSTETRICAL SOCIETY

A RECENT meeting of this society, held at Birmingham, was devoted to a discussion on

Eclampsia and Pre-eclamptic States

Mr. S. W. MASLEN JONES (Wolverhampton) said that since the Obstetrical Congress of 1922 there had been a general adoption of purely medical treatment in eclampsia as opposed to active obstetrical interference. The essentials in treating eclampsia and pre-eclampsia were similar—namely, (1) rest; (2) starvation, giving nothing but water for 24–48 hours, and then adding fruit juice, carbohydrates, and milk; (3) intestinal lavage and saline purgation; and (4) free intake of alkaline fluids. In eclampsia nursing in the left lateral position was essential, because it allowed escape of blood and mucus from the mouth and air-passages; lavage of stomach and colon should be done as a routine leaving magnesium sulphate in the stomach. In unconscious patients fluid should be given per rectum; if this was returned, intravenous or even submammary salines might be necessary. Fluids should never be "pushed," however, before the bowels were acting freely, since there was a danger of waterlogging the patient. The value of drugs was disputed: morphia in a dose of up to gr. $\frac{1}{2}$ was useful for controlling restlessness during labour, but it often failed to stop fits, and was not entirely safe in cases with pulmonary oedema. Induction of premature labour was not done often enough in eclampsia: if there was no conspicuous improvement in the patient's condition, and no sign of spontaneous onset of labour, after 24 hours' medical treatment labour should be induced by aspiration of liquor amnii with the Drew Smythe catheter. In severe pregnancy toxæmia, without fits, the use of induction called for much discrimination. After the 36th week he advised induction in severe cases which had responded to treatment, whereas before this time medical treatment should be continued unless the patient was getting worse, since the viability of the child was of importance; but in the latter type of case it must be remembered also that intra-uterine death of the child was common.

Mrs. BERTRAM LLOYD agreed that it was dangerous to give too much fluid in the early stages of treatment; she advised induction in cases of pre-eclampsia

if medical treatment produced no improvement within three weeks. In her experience eclampsia was rare in hospital cases. At the Birmingham Maternity Hospital there had been 87 cases in the past six years. Delivery was spontaneous in 56 cases; forceps were used in 19; Cæsarean section was done once. In 4 cases labour was induced, and 6 patients died undelivered. The maternal death-rate was 25 per cent. and the fetal 47 per cent.

Mr. ALFRED DANBY said that as the primary cause of the pre-eclamptic state was still unknown, all forms of treatment for this disease (or syndrome) must be empirical. Recent experimental work in America suggested that some of the untoward symptoms of eclampsia were due to "water intoxication," and he wondered whether this suggestion would have any influence on the fetish for forcing fluids to dilute the "toxins." The three cardinal signs of pre-eclampsia were raised blood pressure, oedema, and albuminuria, of which the last-named was probably the least important. It was now known that water retention could occur without visible oedema, and any undue gain in weight in the last trimester of pregnancy was suggestive of this so-called "hidden oedema." The generally recognised fact that free diuresis was usually followed by rapid improvement in the general condition seemed to indicate a functional rather than organic derangement of the kidneys. In this connexion Mr. Danby was particularly interested in the work of Hoffmann and Anselmino (1931) who were able to demonstrate that the blood of eclamptics contained two components of the posterior lobe hormone—namely, the anti-diuretic and the pressor. These factors were not present in the blood of normal women, pregnant or otherwise. Goodall (1933), commenting on this work, which was done upon rabbits with controls, considered that it showed a consistent uniformity of reaction that placed the antidiuretic content of the blood of these patients beyond doubt; the pressor substance was present only in cases of high blood pressure, 180 systolic or over. It appeared, however, that Hoffmann and Anselmino's observations had not yet been confirmed by other workers. Whilst the physiology and pathology of water metabolism was still imperfectly understood, the speaker felt that it had a considerable bearing on the subject under discussion. During the past few years he had treated a number of cases of pre-eclampsia showing oedema by fluid limitation and dehydration—a method modified from that of Arnold and Fay (1932). The results had been excellent as far as they went, but the cases were specially selected. In many instances the change in the external appearance of the patient and the reduction in weight due to loss of fluids was very striking. Although the diet contained over 50 grammes of protein, including meat, he had seen no ill-effects from its use; but most of the patients complained of thirst. In eclampsia he was convinced that the injections of hypertonic solutions had given improved results, probably through dehydration and diuresis. He usually employed a 25 per cent. solution of glucose intravenously, but occasionally intramuscular injections of 25 per cent. magnesium sulphate were given in addition. The free use of sedatives, including Sodium Luminal hypodermically, were part of the routine treatment, and all forms of interference—such as colon wash-outs, rupture of the membranes, and application of forceps—were done under chloroform anaesthesia. The objection to the use of small quantities of chloroform was in his opinion more

academic than real. As regards Cæsarean section, although he admitted there might be an occasional case where it should be done, he had never had occasion to perform the operation for eclampsia.

Mr. H. L. SHEPHERD said that in Bristol eclampsia was becoming less common; during the past ten years he had seen 80 cases, with 9 deaths, whereas before the war the average was 15 cases per annum. He believed that eclampsia and pre-eclampsia should be treated on different lines; for although the primary toxin was undoubtedly formed in the placenta, the fits were caused by absorption of toxic products from the bowel. The greater number of deaths in eclampsia were due to intracranial hæmorrhage, a direct result of the high blood pressure and the fits. Hence the most important part of the treatment of eclampsia was to reduce the blood pressure and control the fits, which he thought could best be done by free venesection and the use of morphia. Subsequently the usual eliminative treatment of the bowel should be adopted and protein omitted from the diet with the idea of sparing the liver and giving it every chance to recover. He considered it dangerous to allow too much fluid. Pre-eclampsia, he believed, was always associated with constipation, which led to the higher breakdown products of proteins being absorbed unchanged. Constipation should therefore be treated energetically. The value of induction of labour lay mainly in the relief of intra-abdominal pressure; hence the fact that withdrawal of liquor amnii through catheters gave better results than bougies. Calcium, both by mouth and intravenously, was of value at all stages.

Mr. WENTWORTH TAYLOR, speaking of the Dublin method of treatment, said that it did not consist in a fixed and unalterable régime. While the basic principles of Tweedy's treatment were still generally applied, each case was dealt with on its own merits. To some extent he had been impressed with the efficacy of the treatment, and in his personal experience of 62 cases he had only had 9 deaths; in all the fatal cases post-mortem examination had revealed some gross failure of the human organism such as cerebral hæmorrhage or massive necrosis of the liver or kidneys, which no form of treatment could be expected to influence. Pregnancy toxæmia could be classified broadly into four separate types. (1) *Pernicious vomiting* should be treated in the first place by securing a proper action of the bowel and by correcting any malposition of the uterus. If this preliminary attack failed the patient lost weight rapidly, continued to vomit, and developed jaundice and acetonuria. In these circumstances delay was dangerous and the uterus should be emptied by abdominal hysterotomy in the sure knowledge that rapid improvement would follow. Evacuation by insertion of tents was too slow. (2) In the *pre-eclamptic state* starvation need seldom be carried beyond two days and never beyond four. If there was no improvement after this time, labour should be induced. Hysterotomy might be necessary in severe cases before the 25th week. (3) In *eclampsia* he advised an initial dose of morphia gr. $\frac{1}{2}$ - $\frac{3}{4}$. If this failed to control the fits a major cerebral lesion was probable, and no further morphia should be given. Venesection was not popular in Dublin, since eclamptic patients were in any case anæmic during the puerperium. Cæsarean section at or near term was never necessary since it was easy to stimulate the uterus to empty. (4) In *toxic antepartum hæmorrhage* treatment by plugging the vagina was seldom attempted now. It was preferable to treat by

puncturing the membranes, allowing the waters to escape and the uterine cavity to close down, after which spontaneous delivery was the rule.

Mr. T. C. CLARE (Leicester) was not convinced that toxæmia was the right descriptive term for the condition under discussion. He was now converted to Paramore's mechanical theory of origin of eclampsia. The essential in treatment was to stop the fits. The results published by Stroganoff were so remarkable that he felt that the danger of using chloroform for this purpose was less than generally believed. He personally used spinal anæsthesia to lower the blood pressure, and regarded it as safer than venesection. It could be repeated if necessary. He asked whether Evipan had been tried for control of the fits. He thought that oxygen played an important part in treatment.

Prof. MILES PHILLIPS (Sheffield) said that eclampsia was rare in treated cases. It was important that the honorary surgeon should see cases of pre-eclampsia at least three times in the 24 hours. At Sheffield they had used the Stroganoff method of treatment since 1922. Induction of labour should be done when a pre-eclamptic patient became worse, and it was important to listen to the fetal heart twice daily. He thought that Veratrone and venesection were both of value, but that it was easy to overdo the administration of fluids. He mentioned that eclampsia was extremely rare in Holland—a fact attributed to the salt-free diet.

Prof. H. J. DREW SMYTHE (Bristol) believed in giving large doses of morphia in eclampsia. He said that a pre-eclamptic required protein to reduce œdema.

Mr. C. L. SOMERVILLE (Leicester) said that in the treatment of eclampsia he advised immediate venesection followed by intravenous anæsthesia, preferably with Pernocton in a dose of from 3-4 c.c.m. There was no risk of damage to the liver. The patient slept for 5-7 hours, and was not restless on waking. Fits were rare after this. The effect of evipan was too transient for its use in eclampsia. He believed in giving pilocarpine to produce sweating.

Prof. D. C. RAYNER (Bristol) advised rupture of the membranes as soon as possible in eclampsia. If pilocarpine was used there was a danger of drowning the patient.

ROYAL MEDICAL BENEVOLENT FUND.—At a recent meeting of the committee 9 new applicants were assisted and 54 grants were renewed. In all the sum of £1680 was voted. The following are particulars of a few cases helped.

Widow, aged 28, of M.B. who died in May, 1935. Both her parents died when she was a child leaving only sufficient money to insure the child's education. In July, 1932, she married, but in May, 1935, the husband died leaving the widow at the age of 28 with two infant children, and a capital sum of £380. The fund and its auxiliary, the Ladies' Guild, will do what is possible to help.

Widow, aged 78, of M.R.C.S. who died in 1890, was found to be living on a yearly income of £66. The fund granted £25 thus raising the income to £91, which is the limit allowed for retaining the State old age pension of £26.

Daughter, aged 37, of M.R.C.S. who died in 1908. After her father's death she was educated from 9 to 15 years at Dr. Barnardo's Home. She then had to earn her own living and went into domestic service. As she is a dwarf she is unable to do any strenuous work and her power of earning is limited. It is estimated that her earnings for the last month at odd jobs was only £2. The fund voted her an allowance of £26.

As this is the centenary year of the fund a special appeal is being made for new subscribers to carry on the work begun a hundred years ago and for donations towards the centenary fund. Cheques should be sent to the hon. treasurer of the fund, 11, Chandos-street, London, W.1.

MEDICAL SOCIETY OF LONDON

Prof. G. E. GASK, the president, took the chair at a meeting of this society on Feb. 10th, when a discussion on the

Treatment of Sterility

was opened by Mr. C. S. LANE-ROBERTS. Absolute sterility in the female, he said, could often be corrected nowadays by plastic operations on the adnexa, and one should seldom give up hope of conception. Most couples should be allowed to go on from twelve to eighteen months without investigation unless an obvious cause was present. The investigation at the Meaker clinic for sterility in Boston was amazingly thorough. The team consisted of a urologist, a gynaecologist, an internist, an endocrinologist, and a clinical pathologist. The basic routine study required a full week and consisted of six steps: the medical histories and examinations of husband and wife; the gynaecological history and abdominal examination; examination of the semen; endocrinological studies of husband and wife; transuterine insufflation; and further necessary medical or surgical procedure. Meaker's nine major headings for the causes of sterility were: deficient spermatogenesis; obstruction and occlusion in the male genital tract; hostility of prostatic-vesicular secretion; faults of delivery and reception of semen; hostility of endocervical secretions; "uterine blockade"; tubal obstruction and occlusion; impassability of ovario-tubal hiatus; deficient oögenesis. Constitutional disorders impaired fertility, and success might be achieved by combating general debility, endocrine dysfunction, metabolic disturbance, and chronic intoxication. The urological examination must be very thorough, but a well-balanced outlook must be maintained. Perhaps the American workers laid too much stress on endocrine disturbance. In an American series of 4000 cases the large bulk of the males were said to have shown anterior pituitary dysfunction with faulty spermatogenesis, some with thyroid deficiency and some with disturbance of the islets of the pancreas. In some cases of male genital hypoplasia it was claimed that the injection of prolan gave promising results. Many cases of sterility were due to inability to perform the sexual act, and simple and direct advice would often be successful.

On the female side, the sooner an external dyspareunia was dealt with the better. Spasm of the pelvic floor muscles was common, and easily and quickly remediable. It was usually neither necessary nor advisable to perform plastic operations on the vagina. Huehner's work on post-coital examination in cases where intercourse failed to produce cervical insemination had led to the conclusion, among others, that the normal alkaline endocervical mucus was an environment favourable to spermatozoa, and that the acid vaginal moisture was hostile. The significance of premature ejaculation was therefore obvious. Marked anteversion of the cervix, so that the external os was covered by the anterior vaginal wall, often went with hypoplasia, scanty periods, an undersized uterus, an elongated cervix, and a pinhole external os. Chemical hostility of the endocervical secretion and serological hostility were probably not very important, and bacterial hostility might be grossly exaggerated. Excessive viscosity in the cervix might, however, be due to bacteria, and a mechanical viscosity to poor cervical drainage; this could be treated by dilatation and draining

for a few days. A douche of dilute hydrogen peroxide or sodium bicarbonate shortly before coitus was useful. Endocervicitis should be thoroughly treated, either by linear cauterisation or by diathermy with the burr or cutting loop. Retention cysts should be dealt with. Curettage of the endocervix and chemical antiseptics seemed quite useless. Chronic passive congestion might be cured by correcting such faults as coital excess or habitual excitation of the female without proper orgasm. The correct treatment of chronic constipation and uterine retrodisplacement also helped. A deficiency of the pre-coital secretions demanded instruction for the husband. There were only two indications for artificial insemination: imperfect "delivery-reception," and hostile endocervical secretion. Uterine blockade mostly implied the deformity of the uterine cavity or obliteration of the tubal lumen by fibroid tumours. A carefully done myomectomy with meticulous hæmostasis was often followed by pregnancy. The mildest gonorrhœal salpingitis caused damage to the tubal mucosa. Puerperal and post-abortive infections might cause adhesions and occlude the tubal ostia.

Of recent years lipiodol salpingography had been almost universally adopted. Ordinary insufflation methods were of help when the tubes were found closed at laparotomy. The best time for tube testing was immediately after a period, when the epithelium was at its lowest. Only a very chronic case was suitable for salpingostomy. Any proposed plastic operation should be thoroughly explained to the couple. In 366 cases treated by Bethel Solomons with tubal resection, 8 per cent. became pregnant and 18 per cent. either became pregnant or showed tubal pregnancy. Adhesions and folds should be dealt with and a prolapsed ovary might be stitched up. Some workers reported success in cases of sterility with mid-menstrual pain by bursting the follicle under anaesthesia, and others by shaving off the surface of the ovary to facilitate the rupture of the follicle. Small X ray dosage was sometimes used for oögenic dysfunction.

Of the constitutional causes, chronic intoxication should be excluded. The diet should be regulated and vitamin E and protein given. Slimming and obesity would both cause sterility. Lack of exercise, over-work, nervous fatigue, and anæmia could be treated by change of habit and scene.

ENDOCRINE FACTORS

Mr. Lane-Roberts summarised Knaus's work on the physiology of ovulation, but set against Knaus's theory of "safe periods" following and preceding menstruation the results published by Dickinson, who found that impregnation could take place at any part of the cycle, including the period itself. He discussed in some detail the endocrine causes of sterility, in relation to the use of oestrogenic and gonadotropic hormones. Thyroid, he said, might be employed with great advantage, even with a normal basal metabolism. Progesterin was remarkably useful in threatened or habitual abortion; in the treatment of sterility it should be given in association with œstrin in the last third of the menstrual cycle in order to prepare a suitable premenstrual nidatory phase. In some cases of primary ovarian failure, 10 units of insulin before breakfast and dinner improved genital function. Out of 150 cases of functional sterility treated by hormones, dilatation and diagnostic curettage, and low-dosage radiation of the pituitary and ovaries, 53 per cent. had become

pregnant and 42 had carried to full term. In the vast majority of cases the infertility factors would be gradually sifted out by general and local physical examination of husband and wife, with appropriate treatment; Huehner's post-coital examination of spermatic fluid; tests for tubal patency; and special measures such as endometrial examination and tests of the basal metabolism.

DISCUSSION

Mr. A. C. PALMER said that by far the commonest cause of sterility in woman was some degree of genital imperfection or under-development, which included acute antelexion. This displacement could not, of course, stop one spermatozoon, but would stop the fluid which carried the sperm cells, especially if it was abnormally viscous. Salpingitis sometimes did not damage the tubes, but filled the pelvis with adhesions which did not necessarily close the abdominal ostium, and yet somehow by their presence prevented the sperm from reaching the ovary. Their simple removal was sometimes followed by pregnancy. Tiny fibroids or fibromyomata and adenomyomata in the isthmus might block a tube so that gas did not pass at 200 mm. Hg, and laparotomy might be justified. He was working on a technique of cutting out the growth together with a large part of the isthmus, making an incision in the top of the fundus, cutting a big channel in the uterus and embedding the ampullary portion of the tube. This had appeared to lead to patency, but its value had still to be proved.

Mr. V. B. GREEN-ARMYTAGE said that anovular menstruation was a far commoner cause of sterility than was generally appreciated. If a very fine curette were passed just before the period and a cheese-paring were taken from the endometrium at the top of the uterus, hypoplasia would be found with no secretory phase. Out of 7 of his patients treated for the first two weeks after the period with 100,000 units of Oestroform twice a week, and with three doses of 30 rat units of Prognon during the last ten days of the cycle, 4 had become pregnant after three months, one with twins. Greater stress should be laid on the value of lipiodol injections, which apart from their diagnostic value were therapeutic in at least 20 per cent. of cases. This procedure was apt to be neglected in London, to the discredit of London gynaecologists. The insufflation test was more or less useless; he had known clubbed or phimotic tubes to be declared patent on the strength of this test. It was a mistake to use catgut, which was easily absorbed, for uterine implantation; silk-worm gut gave far better results.

Dr. WILLIAM MOODIE drew attention to the psychological factors which might cause sterility in apparently normal couples, some maladjustment or imbalance preventing successful coitus. A faulty attitude to sex, the married situation, and life generally explained many such troubles. Mental causes might have actual physiological repercussions, and mental and physiological readjustment must proceed together. A person might be sterile with one partner and fertile with another.

Mr. W. MCK. McCULLAGH said that he could not understand why lipiodol should pass through a tube if gas could not. Patients surprisingly often became pregnant when their tubes were not patent to ordinary gas. The tubes might open some days after an unsuccessful insufflation. Fear probably had an influence in sterility; a certain veterinary

surgeon had owed his great reputation for the successful mating of horses to his practice of thoroughly startling the mare first by chasing her round the yard with a whip. The speaker claimed 48 per cent. of successful results with insufflation in a series of 50. Impregnation might be achieved by stopping the husband's tobacco, ordering a seaside holiday, or giving thyroid and calcium, which latter increased sexual desire in females.

Mr. GREEN-ARMYTAGE answered that Rubin had established that carbon dioxide caused spasm of the tube whereas lipiodol did not; moreover, the gas had therapeutic value in only 10 per cent. of cases as against the 20 per cent. of lipiodol.

Mr. JOHNSTON ABRAHAM suggested that better results might be obtained if the husband was always sent to a urologist. Sterility due to the male was far higher than the 12 per cent. mentioned by Mr. Palmer, and it was easy to see whether a man was fertile or not by semen examination. In a case of double epididymitis, implantation of the vas into the top of the epididymis might cure the sterility. Recent gonorrhoea did not sterilise a man, but chronic prostatitis would thicken the spermatic fluid and impede the action of the spermatozoa. Many men were impotent though quite fertile, and in these cases artificial insemination might be performed.

Dr. HENNING BELFRAGE laid stress on the importance of diet and the necessity of correcting vitamin imbalance, especially in city-dwellers.

Mr. HOPE CARLTON inquired about the incidence of sterility in men after operation for neoplasm of the prostate. If the enlargement was of the whole prostate, he suggested, fertility would probably be destroyed, but an adenomyoma might leave it unimpaired. Young's operation had become popular in America because it was believed not to cause sterility. The closure operation by the Harris technique was said to allow the spermatozoa to pass without being lost in the bladder.

THE FOTHERGILL TESTIMONIAL FUND

THE following is the second list of subscriptions received in response to the letter published in the *British Medical Journal* and *The Lancet* of Jan. 18th :

Amount previously acknowledged, £262 14s. 6d.
 Lord Dawson of Penn (London), £5; R. Langdon-Down (Teddington), £10 10s.; G. T. Willan (Hove) and G. C. Trotter (London), each £1 1s.; J. C. Loughridge (Belfast) and J. Armstrong (Ballymena), each £1; W. W. Shrubshall (Burgess Hill), £2 2s.; T. Brice Poole (Hove), £3 3s.; J. Manson (Warrington), £2 2s.; H. S. Souttar (London), C. O. Hawthorne (London), and Bolton Local Medical and Panel Committee, each £5 5s.; J. Mills (Ballinasloe), Isle of Wight Local Medical and Panel Committee, G. Morgan (Brighton), and Mid-Cheshire Division, B.M.A., each £1 1s.; Portsmouth Division, B.M.A., £5 5s.; W. C. Chaffey (Hove), £2 2s.; W. Gosse (Wimborne), £5; J. Henderson (Glasgow), £2 2s.; E. Kaye Le Fleming (Wimborne), £5 5s.; Halifax Panel Committee, £2 2s.; Sir Humphry Rolleston (Haslemere), £5 5s.; Shropshire and Mid-Wales Branch, B.M.A., £2 0s. 6d.; S. Watson Smith (Bournemouth), £2 2s.; H. C. Jonas (Barnstable), £5; J. B. Miller (Bishop-briggs) and B. E. A. Batt (Bury St. Edmunds), each £1 1s.; R. G. Gordon (Bath), £3 3s.; Berks Panel Committee, £5 5s.; West Suffolk Panel Committee, £10 10s.; L. Kilroe (Rochdale), £5; C. L. Batteson (London), J. C. Lyth (York), A. K. Smith-Shand (York), and W. V. A. Kelly (York), each £1 1s.; Wakefield, Pontefract, and Castleford Division, B.M.A., £3; H. E. Barrett (London) and J. A. Brown (Birmingham), each £1 1s.; H. S. Beadles (Romford), £5 5s. Total £336 7s.

Cheques should be made payable to the Fothergill Testimonial Fund, and addressed to the treasurer, Fothergill Testimonial Fund, British Medical Association, B.M.A. House, Tavistock-square, London, W.C. 1.

REVIEWS AND NOTICES OF BOOKS

The Natural History of Disease

By JOHN A. RYLE, M.A., M.D., F.R.C.P., Regius Professor of Physic in the University of Cambridge; Consulting Physician to Guy's Hospital. London: Humphrey Milford, Oxford University Press. 1936. Pp. 438. 15s.

To Dr. Ryle's many friends—colleagues, pupils, patients—his new title of Professor must still sound a trifle strange. It carries with it a faint suggestion of intellectual detachment, of academic as distinct from broadly human attitude, which are no part of his character and work as they are known. He has long stood high in the esteem of the English medical world as a general physician—"albeit with an abdominal bias," as he puts it. That is a greater achievement than the industrious ascent of a specialist ladder, and the method and the philosophy that lie behind it are to be gathered from this series of his papers assembled from the medical journals of the past decade. Ten of them, representing the bias, deal with gastro-intestinal subjects, and another score or so with other diseases or symptoms. What do I know about this condition? In what sorts of patients have I met it? In what circumstances? What course does it follow? How precisely can its manifestations be described? What then can I infer about its cause, or its significance, or its later behaviour?

Such questions as these seem to have been the starting point of each essay, and the next step every time was to bring out the writer's own case records and examine them. "Full notes, frequently perused, are the essence of clinical education." There emerges a clinical description, or a discussion of relationships, that is usually simple and direct, yet in some way illuminating, setting matters in a better perspective. The method so exemplified is frankly preached in the opening paper and in one or two at the end of the book. It is the method of the field naturalist, who watches—pencil and notebook in hand—the play and interplay of natural forces and the behaviour of living things. It demands quick and full and accurate observation, immediate and correct recording, and a close examination of the facts in search of sequences and relationships. Dr. Ryle's belief is that this method, old as Hippocrates, is by no means outworn; there are many facts yet to be observed by watching different diseases in different men, and much useful knowledge to be had from studying them. The newer experimental method, applied directly in man to the problems of disease, has its own value and its own field, but the whole future does not lie with it. Medicine, as both art and science, will be not only well practised but also carried forward by the physician with the touch of the naturalist in him, gaining a wide experience and using it wisely and critically. This is sound philosophy. It denies nothing to the experimental method except monopoly. It needs emphasis to-day, not because the experimental method challenges it, but because the development of specialisation, the advent of numerous physical and chemical methods, and commercial enterprise in the therapeutic field have combined to foster in the clinician a neglect of his peculiar opportunity, and a narrow and uncritical attitude.

No one can be in a better position to oppose those tendencies than the professors of medicine, and it is significant that Dr. Ryle, on becoming one

of them, should re-emphasise the value in medicine of a broad basis of experience and a closer observation of the natural history of disease.

The Minor Medicine of General Practice

By L. V. SNOWMAN, M.A., M.B. Cantab., M.R.C.P. Lond., Physician to the Eastern Dispensary; Assistant Pædiatrician, Jewish Maternity Hospital. London: John Bale, Sons and Danielsson, Ltd. 1936. Pp. 104. 2s. 6d.

PATIENT and doctor will continue to disagree about what constitutes minor medicine so long as the former thinks in terms of discomfort and the latter in terms of prognosis. Although Dr. Snowman's little book, despite its title, discusses a number of morbid conditions which will be regarded as minor by neither patient nor doctor, for the most part his comments on their causation and treatment will be found apposite and useful. In the chapter on coryza, though rightly condemning central heating as a predisposing factor, he advocates the use of watery douches in the treatment of nasal obstruction where many nowadays prefer oily sprays. He says, rather surprisingly, that it is rare for a respiratory infection in a well-nourished individual to cause a true bronchitis and omits to mention a rapid pulse as an early, and often solitary, physical sign of phthisis. The point that unexplained pain, labelled *faute de mieux* rheumatic fibrositis, often turns out to be due to herpes zoster is well taken, and if borne in mind may do much to enhance a doctor's reputation. Dr. Snowman believes that children must be hardened to our inclement weather if rheumatism is to be prevented, and he is eminently sane on the bog of constipation. In the dietary advised for simple diarrhoea he makes no mention of weak tea, the astringent action of which has much to commend it. In the chapter on cardiac disorders he perhaps lays undue stress on the height of the systolic blood pressure and too little on that of the diastolic, and he claims that the "trained finger" can diagnose hypertension—a debatable point. His remarks on so-called depressor substances are, however, sensible and timely.

Altogether a well-written and sound little book.

Notable British Trials

Trial of Alma Victoria Rattenbury and George Percy Stoner. Edited by F. TENNYSON JESSE. London and Edinburgh: Wm. Hodge and Co. 1935. Pp. 298. 10s. 6d.

THE sixty-fourth volume in the series of Notable British Trials contains the proceedings against Mrs. Rattenbury and George Stoner for the murder of the former's husband at Bournemouth less than a year ago. The masterly handling of the trial by Mr. Justice Humphreys would alone make the book worth study. If the Court of Criminal Appeal found it merely "a sordid and squalid case," Miss Tennyson Jesse rehabilitates romance in a pleasantly provocative Introduction.

Stoner, aged 18, was engaged as chauffeur by Mrs. Rattenbury, aged 38, and her husband, aged 67. Within two months she gave him a bedroom inside the house and became his lover; within six months her elderly husband was discovered dying with his

head battered in. A doctor, hastily summoned late at night, found Mrs. Rattenbury in a state of drunken excitement, with a gramophone playing and all the lights on. She kept saying she had killed her husband and, when formally charged, said "I did it deliberately and would do it again." She was tried jointly with Stoner on an indictment for murder; she would have been guilty in law if she had counselled or advised the deed even if she had not been present when the blows were struck. She went into the witness-box, denied her guilt without casting any blame on Stoner, and was acquitted. Stoner, who had told the police that he struck the blows, did not go into the box and was found guilty. It was said for him that the Rattenburys were going on a visit, that he was morbidly jealous at the prospect of his mistress resuming marital relations with her husband, and that he hit the husband to give him some hurt which would stop the visit rather than to kill him. It was a hopeless defence. There was also a curiously fugitive suggestion that young Stoner was a cocaine addict, suffering from insane hallucinations. His counsel asked the jury to say Stoner was either "guilty but insane" or else guilty of manslaughter and not of murder. The judge told them he saw no ray of evidence to support insanity. Stoner's counsel had said "he does not deny that it was his hand that struck the blow." As the judge observed, counsel cannot properly make an admission in a criminal case when the client is not put in the box. Three days after Stoner's conviction and her own acquittal, Mrs. Rattenbury committed suicide with remarkable determination, stabbing herself in the breast six times with a knife (three of the wounds penetrated the heart) on the bank of a stream whence her body fell into the water. Stoner's appeal was dismissed, but he was reprieved. Somewhere he is alive, not yet 20, and with his story and his portrait in this book ready to help the public not to forget him when he is free. Is this quite fair?

The Gallic *esprit* of Miss Tennyson Jesse scores several points against our insular prejudices. She derides the Anglo-Saxon attitude of contemptuous condemnation towards the man and woman (and especially the woman) unlucky enough to be found out in sexual delinquency. If Mrs. Rattenbury suffered from nymphomania, the fact was not admirable but neither was it blameworthy. Another Anglo-Saxon trait is attributed to the judge when he stigmatised the husband as a "*mari complaisant*, not a nice character"; Mr. Rattenbury's indifference was "not necessarily a despicable attitude." Worst, and most Anglo-Saxon of all, is the idea that Mrs. Rattenbury, being older, dominated the much younger man. The truth is, says the Introduction, that no woman is so completely dominated by her lover as the elderly mistress of a very young admirer. In support of this thesis Miss Tennyson Jesse prints a singular letter by Benjamin Franklin to a young man on the advantage of choosing an elderly mistress. It is frank enough to bring a blush to the marble of his statues in Philadelphia and other transatlantic towns where the inscriptions credit him neither with cynicism nor with sophistication. The Introduction criticises the reiteration by judge and counsel of the words "adulterous intercourse." The assize court, it reminds us, is a court of law and not of morals. But the law, having to assess the truthfulness of a witness, considers itself entitled to take into account the witness's character. And the prosecution was inviting the jury to consider whether a woman might not be so lost to decency that, to gain her ends and

particularly for sexual gratification, she would stop at nothing, not even at murdering her elderly husband—especially if she had not to strike the blow herself. Miss Tennyson Jesse's lively advocacy of Mrs. Rattenbury rebuts the suggestion and makes an interesting study of character.

The Patient and the Weather

By WILLIAM F. PETERSEN, M.D. Vol. I., Part I. The Footprint of Asclepius. Michigan: Edward Bros., Inc. 1935. Pp. 127. \$3.75.

THE second and third volumes of this voluminous work have already been reviewed in THE LANCET, when it was stated that there was inevitable delay in producing the first volume. And now that the first volume arrives it is described as Part I., so that the general introduction is not yet complete. What we have now is an interesting essay on Greek medicine with its different approaches to medical problems, while an able summary of Hippocratic arguments leads up to detailed information as to the influence of the weather in relation to particular diseases. Here racial differentiation is taken into consideration, although this side has been dealt with in another section. These chapters are profusely illustrated with maps showing the percentage distribution of the "old-age group" (65-75 years) in the United States, and the distribution of this group for the coloured races, the information being obtained from the U.S. census of 1930. Other maps figure the distribution in various States of under-height, under-weight, myopia, defective hearing and teeth, mortality of infants from malformation, distribution of various forms of insanity, and suicide rates. The general suggestion in these chapters may be fairly summed up by considering that variations of disease based on environment may be mainly referred to climate and the mutations of weather. One such generalisation may be quoted: "Wherein lies the difference in the European environment and the American? Wherein the energizing effect? What can cause the increase in autonomic dysfunctions? I believe the explanation is a relatively simple one. While it is true that Europe has a typically cyclonic climate, the cyclonic disturbances are neither as frequent nor as violent as those in America. In Europe the rate of travel of the storms is only about half that of the speed that they attain in America. Very rarely does the degree of barometric fluctuation reach the amplitude that we find so common along our storm tracks. It is the abruptness of the autonomic adaptation demanded by these changes that is of greatest moment."

The completion of Vol. I. has still to appear, and it is not quite clear in how many parts that will be issued. So no attempt can be made to estimate definitely the value of this large and far-reaching production until the remainder comes under review. It seems likely that part two of Vol. I., announced as shortly forthcoming, may not prove the conclusion of the work. Enough has been published to show that Dr. Petersen is supplying the medical profession, and the public, with a compendium which must prove a useful book of reference. The second and third volumes were reproduced by lithoprinting so that a considerable saving of expense was brought about. In the first volume the ordinary method of production has been followed, and both the type and the definition of the illustrations may be commended.

REPORT OF THE DEPARTMENTAL COMMITTEE ON CORONERS

THE departmental committee appointed by the Home Secretary in February, 1935, to inquire into the law and practice relating to coroners, and to recommend what changes are desirable and practicable, has brought in its report (H.M. Stationery Office. Cmd. 5070. 1s. 3d.). The committee was made up of Lord Wright (chairman), Sir Archibald Bodkin, Sir Farquhar Buzzard, M.D., Mr. Digby Cotes-Preedy, K.C., Sir Arthur Hazlerigg, Mr. George A. Isaacs, Mr. W. Rutley Mowll, Mrs. Margaret Winttingham, with Mr. A. Johnston, of the Home Office (secretary). The committee held 19 meetings and examined 68 witnesses. Its main recommendations are summarised for reference as follows:—

The office of coroner should be retained, the coroner's jurisdiction being limited to the investigation of the facts how, when, and where the death occurred and this investigation of facts being clearly distinguished from any trial of liability, whether civil or criminal.

In cases of suicide the press should be prohibited from publishing an account of the proceedings at the inquest; though the inquest should be held in public, as at present. All that the press should be allowed to publish is the fact that an inquest has been held, the name and address of the deceased, and the verdict that the deceased died by his own hand.

The verdict of *felo de se* should be abolished, and the verdict in cases of suicide should simply be that the deceased died by his own hand.

No inquiry into the state of mind of the deceased should be made in cases of suicide save in so far as it might throw light on the question whether he took his own life, and no reference should be made in the verdict to the state of mind of the deceased.

The coroner should no longer have the power to commit any person for trial on the inquisition on a charge of murder, manslaughter, or infanticide; and the inquisition should not name any person as guilty of one of these offences.

In any case in which questions of criminality are involved the laws of evidence should be observed; and where a person is suspected of causing the death he should not be called and put on oath unless he so desires, and should not be cross-examined.

A coroner should be obliged to adjourn an inquest for 14 days, if requested to do so by a chief officer of police on the ground that he is investigating the circumstances of the death to determine whether he should proceed for an indictable offence; and the inquest should be adjourned for further periods of 14 days if the chief officer of police repeats his request.

Coroners' courts should be prohibited from dealing with questions of civil liability.

Verdicts, or riders to verdicts, of censure or exoneration should be prohibited, but this prohibition should not extend to recommendations of a general character designed to prevent further fatalities.

The coroner should have a discretion to dispense with the holding of an inquest in the case of deaths due to simple accidents, or to chronic alcoholism, and likewise in the case of deaths under an anæsthetic or during an operation. He should be obliged to hold an inquest in cases of suspected industrial disease.

Arrangements should be made to ensure that post-mortem examinations in cases of deaths due to anæsthetics are carried out expeditiously.

Post-mortem examinations ordered by coroners should, save in exceptional cases, be made by pathologists whose names appear on a list to be kept by the Home Office. In compiling the list, the Home

Secretary would be advised by an expert advisory committee. There should be a special list of pathologists competent to conduct post-mortem examinations in certain cases of industrial disease.

The coroner, if so requested by a chief officer of police before the conclusion of an inquest, should direct a post-mortem examination to be made. If an inquest is not being held, or an inquest has been concluded, the chief officer of police should have power to order a post-mortem examination subject to the approval of the Director of Public Prosecutions.

Steps should be taken to secure the provision of better mortuaries and of places for post-mortem examinations.

A Rules Committee should be established to make rules for the conduct of inquests and the procedure to be followed by coroners generally. The committee should consist of persons appointed to represent the Lord Chancellor, the Home Secretary, Coroners Society, General Council of the Bar, Law Society, British Medical Association, and general public.

A Disciplinary Committee, similarly constituted, should be created to deal with complaints about the conduct of coroners.

Coroners should give, where practicable, reasonable notice of the time and place of inquests, especially in cases of industrial disease.

The coroner should have a discretion to view or not to view the body.

The London County Council should be empowered to prepare a scheme for the approval of the Home Secretary, setting out the areas to be served by each coroner's court provided by the council.

The provisions of Section 84 of the Coal Mines Act, 1911, in regard to the notification of inquests and representation of interested parties, should be extended to all industrial cases.

Coroners should keep adequate records of the evidence taken before them at inquests, and copies should be available to any person who shows proper cause on payment of a fee.

In these cases in which the coroner has at present a discretion to dispense with a jury, he should in future sit without a jury, unless there are reasons which appear to him to render the presence of a jury desirable.

In jury cases the coroner should be empowered to hold a preliminary sitting of the inquest where desirable without the presence of a jury, for the purpose of receiving evidence of identification and issuing a burial order.

Juries should be drawn from the jury list and, where a jury is empanelled in an inquest on a woman, child, or infant, at least two women should serve on the jury.

Steps should be taken, whenever practicable, to merge the smaller coroners' jurisdictions in larger areas.

In future, only solicitors or barristers should be appointed as coroners, but, whenever possible, they should have had experience as deputy coroners and should have a knowledge of forensic medicine.

Coroners should not act in their professional capacity as solicitors in matters which have been the subject of investigation at inquests held by them as coroners.

Deputy coroners and assistant deputy coroners should be appointed and paid by the same authority as appoints the coroner, after consultation with the coroner to whom the deputy is being appointed.

A coroner's officer should in all cases be a serving police officer.

Legislation will be required to give effect to most of these recommendations. The report is signed by all the members of the committee except Mr. Mowll, who submits a minority report. Sir Archibald Bodkin signs subject to reservations set out in a memorandum. Comment is made in a leading article on p. 377.

THE LANCET

LONDON: SATURDAY, FEBRUARY 15, 1936

THE FUTURE OF THE CORONER

UNANIMITY is a cardinal virtue in a Royal Commission or Departmental Committee. The Committee on Coroners is unanimous on one point only—namely, that the abolition of the coronership is neither practicable nor desirable. It has examined the Scottish system of private investigation of unnatural deaths by the procurator fiscal and does not find its adaptation to England to be feasible. The reason is that the procurator fiscal's inquiries in Scotland are part of his ordinary duties in the prosecution of criminal offenders on behalf of the Crown. As has been pointed out in these columns, there is no such exclusively official scheme of prosecution in England where the proportion of indictable offences undertaken by the Director of Public Prosecutions is much less than one per cent. of the total. The conclusions of the Committee's report (Cmd. 5070. H.M. Stationery Office. 1s. 3d.) are printed on another page. Some of them, as we shall see, involve fresh legislation. But it is noteworthy that one experienced legal member of the Committee, Mr. W. RUTLEY MOWLL, found himself unable to sign his colleagues' report, while Sir ARCHIBALD BODKIN, who speaks with almost unique authority on the administration of the criminal law, signs it subject to weighty comments and reservations. It may well be, therefore, that a Coroners (Amendment) Bill will not be introduced immediately.

Several of the current complaints of coroners' practice and procedure, declared by the Committee to be well founded, are criticisms which the more judicious coroners escape. They are points in which the high level of the best of these tribunals could be uniformly attained by all if attention were drawn by Home Office circular to what needs to be avoided. Coroners ought to know, for instance, that the law courts condemn the employment of the same persons as jurors at inquests again and again. The decision in *R. v. Divine, ex parte Walton* in 1930¹ left no doubt about this; yet the Committee is told of a town where the coroner's jury regularly consists of the inmates of the workhouse. Such a practice is a scandal; the Committee recommends legislation to secure that inquest jurors be chosen from the ordinary jury list and that at least two women jurors be summoned where the inquest concerns a woman, child, or infant. Another indefensible impropriety is the making of irrelevant animadversions upon the conduct of persons who are in any way brought before the tribunal. The Committee cites an inquest upon a girl of 19 who was said to have had sexual

relations with a much older married man. Medical evidence entirely disproved an allegation that he had been responsible for her death; yet the coroner, at the request of the jury, went outside his province and censured the man for his relations with the deceased. Other coroners, the Committee says, use their public position to attack the beliefs held by Christian Scientists or to criticise the administration of a hospital, the status and competence of its medical staff, and the specific method of a patient's treatment. Thus an individual finds himself condemned without redress or right of appeal. The Committee insists that this practice must stop. It desires also to prohibit coroners' juries from bringing in riders imputing responsibility (even where moral blame is disclosed) or purporting to exonerate. The only permissible riders, it insists, are those which contain proposals for limiting the recurrence of fatalities. Interested parties are all too fond of turning an inquest into a skirmish over civil liability, groping for admissions which may later be useful in the county court or High Court and wasting time over minor allegations of negligence which are outside the plain issue before the coroner. The purpose of an inquest is, after all, made clear by Section 4 of the Act of 1887. The inquisition is to elucidate three matters—first, the identity of the deceased; secondly, how, when, and where he came by his death; and thirdly, if he came by his death by murder or manslaughter, the persons (if any) whom the jury find to have been guilty.

Hitherto we have mentioned criticisms which, if all coroners had been blessed with the wisdom of Solomon, no Committee need have been constituted to meet. We come now to the Committee's proposals for altering the law in directions where the best of coroners could take no step unless Parliament first decides the policy. The Committee recommends that the third of the above-mentioned statutory purposes of an inquest be cancelled, that the inquisition should no longer name anyone as guilty of murder, manslaughter, or infanticide, and that the coroner should no longer have power to commit persons for trial. If questions of criminality arise, the laws of evidence are to be observed; if a person is suspected of having caused the death, he is not to be called and put on oath unless he so desires, and he is not to be cross-examined. Already, under Section 20 of the Act of 1926, inquests are adjourned as soon as criminal proceedings are launched before the magistrates. It is unnecessary and inconvenient to have two concurrent investigations, and the coroner stands aside when the ordinary procedures of prosecuting an offender are definitely taken. In future, the Committee proposes, the coroner will adjourn at the request of the police on their mere assurance that prosecution is possible. The coroner is also to direct a post-mortem examination, if the police so desire, before an inquest is ended. If an inquest is not held, or if it is already over, the police are to have power to order a post-mortem examination subject to the approval of the Director of Public Prosecutions. These proposals are evidently based

¹ THE LANCET, 1930, i., 426.

on two ideas—the unfairness of a coroner plying a suspect with questions, and the uselessness of the inquest as an aid to the police in the detection of offenders. On this latter point the experts differ. The majority report of the Committee assumes that the inquest can contribute little, even in poisoning cases. A witness from Scotland Yard declared that the private questioning by the police of possible witnesses or possible suspects was more likely to elicit information than the proceedings at an inquest. Moreover, witnesses who represented the police forces outside London disclaimed any desire to use inquests as a means of extracting incriminating information. But there may still be old-fashioned folk who fear that private questionings by the police can be as grave an abuse as public interrogations by a coroner. Sir ARCHIBALD BODKIN points out that, if essential witnesses refuse to disclose their knowledge to the police, and if there is consequently not enough evidence to justify an arrest, the present system of the inquest is the only other method of compelling disclosure. He regards the coroner's powers in such cases as valuable adjuncts to the present administration of the criminal law.

There will probably be less controversy over the Committee's recommendations as to cases of suicide. Until modern times the law lagged behind the public intelligence. It dealt with self-murder (*felo de se*) by forfeiting the dead man's goods to the Crown and by burying his body at the cross-roads without religious ceremony and with marks of infamy in order to mark the ecclesiastical condemnation of his offence. The verdict of unsound mind became popular to mitigate these harsh consequences. It has outlived the conditions which were thought to justify it, and, if it were taken seriously, it would confuse the national statistics of crime and insanity. If the law applied to suicides the same tests of criminal responsibility as are insisted upon in the criminal courts, few persons who have taken their own lives would be found of unsound mind. To remedy this curious convention of insanity at inquests, the Committee boldly proposes (as did the Chalmers Committee on Coroners in 1910) to abolish the verdict of *felo de se* in the coroner's court; it will no longer be his duty to attribute felonious responsibility; the verdict will simply be that the deceased died by his own hand. Further, to prevent the imitative suicide and the publicity which relatives must find so painful, the press is to be prohibited from giving an account of inquests on suicides. The inquest is still to be held in public but the newspapers are to publish only the fact of the holding of the inquest, the name and address of the deceased, and the bare verdict that he died by his own hand. This will involve legislation on the lines of the Judicial Proceedings (Regulation of Reports) Act, 1926, which was passed to suppress unsavoury details, especially in divorce cases. The proposal will encounter not only the opposition of the journalists but also the practical difficulty of the coroner, who cannot announce that the case is one of suicide until the verdict is returned. The Committee

suggests that he should state at the outset that a verdict of suicide is possible, whereupon the press would be forbidden to publish any account till the verdict was ascertained. If the law eliminates from inquest verdicts all reference to the deceased's state of mind in cases of suicide, coroners will no longer need to read in court letters and other intimate documents written by him which are often painful and harmful to living persons. It may still be necessary to inquire into the state of a dead person's mind in order to decide whether he took his own life; suicide may still remain self-murder in law; but a great reform will have been achieved if the Committee's proposal receives effect.

Other recommendations are important to the medical profession. It is proposed that post-mortem examinations, ordered by coroners, be made by pathologists whose names are on a national panel constituted by the Home Office with the guidance of an expert advisory committee. A special panel would be available for cases of industrial disease, and it is suggested that the Coroners Acts be amended to include among unnatural deaths any death believed due to illness or disease (including poisoning by gas, vapour, or fumes) resulting from the nature of an employee's work. In recognition of the higher standard required of pathologists on the Home Office panels it is proposed that the post-mortem fee be raised from two to three guineas and that travelling expenses and a fee for attendance at the inquest be allowed. At the same time it is suggested that the ordinary medical attendant of the deceased should be entitled to an appropriate fee for supplying a report on the case or attending an examination. It is often important to collate the clinical and the post-mortem evidence. A further recommendation that better provision be made for mortuaries and places for post-mortem examinations was long overdue. A few important miscellaneous recommendations remain to be mentioned. It is proposed that the coroner should have discretion to dispense with an inquest where deaths are due to what the Canadian laws call "mere accident or mischance," or to chronic alcoholism or where death occurs under an anaesthetic or during an operation. It has long been a matter of comment that in one coroner's district a major operation resulting in death becomes the subject of an inquest, while in another district a similar case is not even investigated by the coroner. Some coroners hold inquests only where death actually occurs on the operating-table, others whenever death occurs before the patient regains consciousness. The previous Committee, which reported in 1910, recommended that all deaths under an anaesthetic should be reported to the coroner, that he should have a discretion as to holding an inquest, and that the hospital or other public institution concerned should hold a scientific investigation. The Minister of Health took up this proposal in 1920, but it has been difficult for hospitals to take action inasmuch as the dead body comes under the control of the coroner.

Lastly, we come to the proposals affecting the

coroner's office. The recent report does not press for whole-time coroners, but it has embodied the suggestions of the Bar Council to the effect that in future only barristers or solicitors should be appointed. It is doubtful whether there is any public demand for this limitation. The inquest in South Dorset on Mr. JEFFERYS ALLEN, an old gentleman of 86 who was found dead with his head against a coal fire, is singled out for prolonged comment by the Committee and indeed is possibly the cause of the Departmental Committee having been constituted a year ago. That inquest was not held by a medical coroner. There are at present in England 268 coroners who are barristers or solicitors, 37 who are medical practitioners, and 4 who have no professional qualifications at all. While it is proposed to eliminate the medical coroner here, it is worth noting that in New York the coroner has been replaced by medical examiners who, since 1918, have sole charge of the medical investigation of sudden, violent, and suspicious deaths. Doubtless in England the influence of the Lord Chancellor makes for a preference for legal coroners. This legal influence it is now proposed to extend by giving the Lord Chancellor fresh powers of removing unfit coroners and by creating two new committees. A Rules Committee is to make rules for procedure at inquests. Naturally much will depend on the nature of the rules. A power to make rules was given to the Lord Chancellor by the 1926 Act and he has made little use of it. The second committee is to be a Disciplinary Committee, apparently on the lines of the tribunal which, under the Solicitors Acts, takes up the grievances of clients and enforces standards of professional conduct. Coroners will be haled before this body for censure. There is no such tribunal where members of the public can obtain redress when annoyed by the behaviour of judges, recorders, or magistrates. If the coroner is worth keeping at all, he should remain as an independent judicial officer who can do his work fearlessly without the risk of being harassed by disgruntled witnesses or unsuccessful advocates.

SALT AND THE SUN

It is difficult for the European to understand the prominence given to salt in the phrase and fable of the East. Here, where its lack is improbable, it ranks merely as one, perhaps the highest, among the condiments: there, it is one of life's necessities; the salt of the earth is second only to the water of life—indeed, the gods, in Egypt for example, have been worshipped as "givers of bread and salt." With animals it is of even greater importance; big game can be induced to forsake an ancient drinking pool simply by moving a block of rock salt, and no herd of cattle is without its licking-stone. In temperate climates this need for salt is not apparent because there is ample in the food to balance excretion. In the tropics, however, its value is shown when it is realised that in the least oppressive circumstances a man may lose by sweating alone as much salt as he normally absorbs from his diet. The average volume of sweat in the hot weather in

India is seven litres a day, containing about 20 g. of sodium chloride, and this is the amount in the normal diet; as the daily requirements in these circumstances are at least 32 g. there is a considerable deficit to be supplied by the tissues. It was to this that, in a letter to our columns,¹ Lieut.-Colonel O. R. McEWEN attributed the vague ill-health and loss of efficiency so common in the white inhabitants of hot countries. Though differing in degree, this state is similar to that giving rise to the severe miner's cramp described by Prof. K. N. MOSS, when the fluid lost by excessive sweating is replaced only by water. Referring to Colonel McEWEN's theory, Sir WALTER LANGDON-BROWN later drew attention² to another and severer form of the condition in the tropics known as functional hypo-adrenalism. He compared it with Addison's disease which is very similar in its great salt excretion, its symptoms of asthenia, lassitude, insomnia, anorexia, and achlorhydria, and its response to sodium chloride. He thought that this knowledge should diminish the zest with which salt-free diets were often prescribed, especially in asthenic states. The effects of a severe deficiency of sodium chloride were described on Jan. 30th at the Royal Society. Dr. R. A. McCANCE had given a diet with the least possible sodium chloride, collecting all the excretions and estimating the sodium in the body. Fluids were not restricted and the low protein was augmented by "ashless" casein. It was found that there was a deficiency of 25-35 per cent. of the body sodium, with symptoms of weakness, fatigue, and muscular cramps; the blood showed a rise in the cell count, viscosity, hæmoglobin, protein, and urea. Health was regained when sodium chloride was restored to the diet. This action does not seem to be purely that of any electrolyte, for E. H. DERRICK found³ that ammonium chloride was ineffective in relieving miner's cramp; the sodium is at least as important as the chloride. These observations show that a large proportion of the indefinite, if not the serious, effects of torrid climates can be avoided, with the intelligent coöperation of the cook, by greatly increasing the salt intake.

The growth of industry and settlement in the tropics has made the whole subject of the effects of great heat one of increasing importance, but as usual ignorance of their nature is betrayed by the confusion in nomenclature. The different types are vaguely and variously called heat prostration, heat exhaustion, heat-stroke, sunstroke, and miner's, stoker's, and fireman's cramp, though the clinical syndromes themselves may be well defined, and there is no better inclusive title than "the effects of heat." The prevention of these is simple, but inventive science seems to have stopped short at punkahs, long drinks, and short shifts. Climate is treated with the same casual tolerance shown to the other states dismissed as being beyond man's control, and even in the last decade the construction of refrigerated offices in Calcutta suffered the editorial scorn of a London newspaper.

¹ THE LANCET, 1935, i., 1015. ² Ibid., p. 1069. ³ Ibid., p. 38.

The human body, however, can adapt itself to conditions with great extremes of temperature, from exploring the Poles to mining in the tropics; it is only when mechanisms fail, which in ordinary emergencies are enough to protect the organism, that illness occurs. Almost always this is due to purely physical changes in the internal fluids, CLAUDE BERNARD'S milieu intérieur, upon the delicate adjustment of which depends the life of every cell. LEE⁴ has divided the effects of heat into four groups: heat cramps, dehydration, heat-stroke in the nervous system, and heat exhaustion in the circulatory; the first two are due directly to

changes in the water-salt balance, and the others to the high temperature. Experiments upon miners on the Rand⁵ and in the Urals⁶ have shown that the great majority of casualties can be prevented by carefully estimating the heat tolerance of recruits and then by acclimatising them with graded work. By such simple measures as good ventilation, light clothing, suitable drinking fluids, and careful training, this type of disease can be limited until it becomes merely the penalty for negligence, instead of a danger to a large part of the population at home and abroad.

ANNOTATIONS

PURIFICATION OF THE HÆMOPHOIETIC FACTOR

PROGRESS towards identification of the hæmopoietic (blood-forming) substances in liver has been curiously slow and discouraging. There are two reasons for the delay: first, experience has shown that most of the chemical methods which would otherwise be appropriate result in inactivation of the product; secondly, it is hard to find suitable clinical cases for testing the activity of isolated extracts. Lately, however, there has been an outburst of successful activity in widely scattered laboratories. Dakin and West in New York last year prepared a substance, to which the name Anahæmin has been given, which appeared capable of inducing a remission when given in doses as small as 80 mg. A few weeks later Strandell and his colleagues in Sweden reported that they had been able to obtain from 100 g. of liver a substance so highly purified that 2 mg. would induce a remission. Two papers published in our present issue record the further progress made in this country, and our readers will agree that the Medical Research Council has performed a useful service in supporting these investigations and in arranging for anahæmin to be submitted to clinical trial under the supervision of acknowledged experts working in conditions which permit of exact control. Prof. Davidson, Dr. Ungley, and Prof. Wayne emphasise the difficulty of assessing potency in tests limited to a small number of cases, but are able to conclude that anahæmin is highly active for blood regeneration; indeed, in their experience no other liver extract given in such small amounts has produced such striking results. Preliminary observations indicate also that this highly purified fraction may prove to be equally potent in the treatment of the nervous manifestations. The English preparation seems rather less active than the original fraction described by Dakin and West, since 80–150 mg. of the latter usually induced a maximal response, whereas the observations of Ungley and his colleagues suggest that only rarely is an average dose of 359 mg. maximally effective. Dr. J. F. Wilkinson likewise confirms the value of the new methods of fractionation introduced by Dakin and West; he found that 58–120 mg. of a fraction similarly prepared were maximally effective. But he has carried purification even further, and gets maximal responses with total doses of only 18–36 mg., representing an original amount of 660–1332 g. of fresh liver. Further

analysis of the chemical nature of this fraction will be eagerly awaited.

Though treatment with the less highly purified preparations already available for parenteral injection is extremely satisfactory if properly carried out, these recent attempts to purify the effective principle are of great theoretical importance; for it is only when the chemical constitution of the effective principles in liver and stomach are known that the complex relationship of these substances will be understood. Castle's original hypothesis that the effective factor in liver is formed by the action of an extrinsic factor (present in beef muscle) with an intrinsic factor in gastric juice has recently been questioned, and an alternative explanation of the observed experimental results is put forward by Greenspon,¹ who suggests, on the strength of experiments at present rather incompletely reported, that it is unnecessary to assume the existence of any extrinsic factor at all. He believes that the hæmopoietic factor in gastric juice is normally inactivated by pepsin; the beef (or other source of extrinsic factor), when incubated with normal gastric juice, binds pepsin and prevents it from inactivating the anti-anæmic principle, but does not provide any other essential principle. The arguments and experiments with which this suggestion is supported are stimulating, but they leave many important points which are more adequately explained by Castle's hypothesis. The answer to these important theoretical problems lies in the hands of the chemists, working in close collaboration with the clinicians, as has been done in carrying out the work reported in our columns to-day.

EXPERIMENTAL HYPERTENSION

THE repercussions of renal disease upon the cardiovascular system are still a subject of lively debate. On the one hand is the incontestable supervention of arterial hypertrophy and persistent high blood pressure upon a primary Bright's disease. On the other hand is the fact that experimental ablation of one or both kidneys has, on the whole, demonstrated that mere reduction of renal tissue will not of itself initiate a rise of blood pressure, though there is reason to believe that gradual reduction of renal tissue, either by excision or by ligaturing vessels, will lead to a rise of pressure when the borderline of the amount of tissue necessary for life is approached. Puzzling and apparently irreconcilable is the occasional finding, in children, of an advanced stage of chronic

¹ Greenspon, E. A.: *Jour. Amer. Med. Assoc.*, January, 1936, p. 266.

Bright's disease without accompanying cardiovascular hypertrophy.

The present impracticability of reproducing in animals a nephritis comparable with Bright's disease in man may be responsible for most of the negative results of attempts to establish an experimental hypertension by means of known irritants. Considerable interest therefore attaches to the claim of Dr. W. M. Arnott and Dr. R. J. Kellar,¹ working in Edinburgh, to have produced hypertension in rabbits by intravenous injection of sodium oxalate. The difficulty of estimating the blood pressure was overcome by a modification of Van Leersum's technique, in which a loop of the carotid is brought to the surface and enclosed in a tubular strip of skin. It is noteworthy that the observed rise of pressure, which appears to be statistically significant, was not maintained for longer than twelve days after which there was "a pronounced instability." Further experiments² were carried out by the same workers on a large series of rabbits in order to elucidate the mechanism of the hypertension. They found that the blood pressure tended to fall after bilateral nephrectomy, and that administration of oxalate to such animals shortened the survival period but did not influence the level of the blood pressure. When one kidney only was removed the usual hypertensive response was obtained with oxalate. Arnott and Kellar therefore concluded that the hypertension was of renal origin. Their view was strongly supported by a further experiment, on a series of 18 animals, in which one kidney was removed and the other denervated. Thirteen animals survived and were then given a course of oxalate injections; no hypertension was observed. The inference from this is that the mechanism of oxalate hypertension in rabbits is of the nature of a nervous reflex. In attempting to assess the importance of these observations it should not be forgotten, first, that oxalate nephritis is essentially a tubular nephritis without demonstrable lesions in the glomeruli; secondly, that the hypertension produced by these experiments appears to be of short duration. In these respects there is a wide gulf between this experimental condition and the nephritic hypertension of man, but the demonstration of a nervous mechanism in any form of hypertension is a progressive step.

OXYGEN DEBT AND CHEST MOVEMENT

In the search for methods of assessing the efficiency of the respiratory apparatus more than one worker has attempted to arrive at some way of using oxygen consumption under fixed conditions as an easily measured test for respiratory efficiency. The use of "oxygen debt" as such a test has certain superficial attractions and, according to a preliminary account³ by H. C. Jacobaeus, G. Nylin, and B. Almberg, may be of some value. Oxygen debt is defined as the amount of oxygen used after cessation of a period of exercise in excess of the resting oxygen utilisation for the same length of time and, although the mechanism is by no means simple, this phenomenon is closely related to lactic acid formation during the exercise. Nylin already claims to have shown that, with a measured amount of work, patients with heart disease have an increased oxygen debt when cardiac failure occurs. In the present study patients suffering from pulmonary disorders, especially advanced silicosis, were found to have

values for oxygen debt in excess of expectation. It was decided to see whether this finding could be connected with diminished movements of the chest wall, and a series of ten subjects were examined with and without constriction of the thorax by means of a stiff belt. This had the effect of reducing an average vital capacity of 4.5 litres to 2.4 litres. The effect of the belt was reflected in the oxygen debt which was always materially increased, in certain instances resembling the type of increase found in severe heart failure. The authors conclude that the mobility of the thorax plays a more important part in the cardio-respiratory functions than had been hitherto accepted. Further investigation which is in progress might well include a study of what is happening in the blood as regards lactic acid and carbon dioxide. The depletion of bicarbonate during exercise has to be made good and interference with respiratory movements must affect the amount of carbon dioxide blown off as well as the oxygen taken in. The links between movements of the thorax and the chemistry of muscular exercise are many, and a wide survey will be needed before it can be assumed that oxygen debt affords a simple test of cardiac or pulmonary efficiency.

EPIDEMIOLOGY OF TUBERCULOSIS

THERE are still some who believe that adult tuberculosis is due to the reawakening of a focus acquired in childhood, and perhaps more who do not admit that the disease is infectious, at all events to a degree which should forbid the association of a patient with other individuals under ordinary conditions of living. Anyone entertaining these beliefs will have them severely shaken if he studies a series of papers recently published¹ by F. M. McPhedran and E. L. Opie, which record the latest results of a study of tuberculosis, with the earlier stages of which many of our readers are familiar. These authors have for years past observed tuberculosis in a large section of Philadelphia, not merely as it affects individuals, but as it attacks families, and their chief conclusion may best be stated in their own words. "The spread of tuberculosis occurs in large part by long drawn-out family or household epidemics, in which the disease is slowly transmitted from one generation to the next."

The evidence on which this statement is based is voluminous, detailed, and closely analysed. The criteria used to determine the existence of the infection are the intradermal tuberculin test, the skiagram, and clinical examination. For purposes of deduction, families are divided into those in which a member has tubercle bacilli in the sputum, those including a member with tuberculosis but without discoverable bacilli in the sputum, and those with no known contact with the disease. The frequency of a positive tuberculin reaction during early years, and of manifest tuberculosis both then and in later years is, in different degrees and at different ages, unmistakably or even overwhelmingly greater in the first two of these categories than the last. It is to be inferred that the absence of tubercle bacilli from the sputum on such occasions as those when it was examined does not mean that they had at no time been present. Findings of this kind have been recorded before; we may recall a report² edited by Dr. G. Lissant Cox on the fate of young children in tuberculous households of Lancashire. What is perhaps more interesting and more contro-

¹ Brit. Jour. Exp. Path., 1935, xvi., 265.

² See THE LANCET, 1920, i., 1201.

versial is the argument used to sustain the thesis that pulmonary tuberculosis in the adult is acquired by recent contact, and does not result from the renewed activity of a focus acquired in childhood. Among the ingenious methods of analysis and presentation by which the authors' extensive data are utilised to this end is the unusual device of the three-dimensional diagram. The whole argument is incapable of condensation, but one item of evidence can be stated quite briefly: it is that among individuals exposed to infection for the first time after 15 years of age nearly 10 per cent. develop manifest tuberculosis, a frequency exceeding that in the general population to much the same extent as that among child contacts in contrast with the children of healthy families. Throughout these studies a clear distinction is drawn between findings in whites and negroes; the different behaviour of the disease in coloured races is hence no reason for refusing to apply their conclusions to any white population.

The authors would have us recognise that pulmonary tuberculosis is an infectious disease, differing from other infectious diseases and concealing its real nature only by the fact that its incubation period is often reckoned in years. Those concerned with the care of the tuberculous should study these papers carefully; it is much to be hoped that similar studies may be pursued in this country by those to whom the opportunity is available.

CATGUT AND TETANUS

SEVERAL cases have recently been reported in this country of tetanus following surgical operation in which catgut has been used as a ligature material, and the question has arisen whether the catgut may not have been the source of infection. The Therapeutic Substances Regulations of 1931 placed the commercial production of sterilised gut under expert control by the Ministry of Health, and since then the risk of non-sterile catgut reaching the hands of surgeons is lessened, if it has not been actually eliminated. An American investigation¹ has suggested that catgut, prepared by commercial firms in several countries of the world, is still often non-sterile. It seems fairly clear, however, that such British material as was used in this investigation dates from the period before the application of Government control. But this control only applies to catgut as it is offered for sale and not to gut prepared in hospitals or by surgeons for use in institutions or private work. From the discussion (see p. 366) last week at the Royal Society of Medicine it is evident that grave risk is being run from the use of catgut prepared under inadequate control. The dry unsterilised gut, used as raw material by some of the smaller hospitals which prepare their own ligatures, teems with micro-organisms—anaerobes and aerobes with their spores—to deal with which demands efficient processes of sterilisation, scientific rather than traditional. As W. Bulloch showed in 1929 it is possible under ideal conditions of manufacture, with the use of heat and certain chemical substances, to prepare catgut which satisfies routine bacteriological investigation. Whether such material will still be proved sterile after it has been subjected to digestion in the tissues remains to be seen; but the clinical experience of hundreds of surgeons, in thousands of cases where standard commercial catgut has been used, suggests that the risk is extremely small. What has been done so successfully in some hospitals should be feasible in others, and the time has come when the sterility of every brand of catgut used by surgeons should

be controlled by standardised investigation. It is urgently necessary that some cheap and efficient method of sterilisation should be placed in the hands of the smaller hospitals and private surgeons who sterilise their own catgut, which, if rigidly followed, would remove a risk which, if numerically small, is yet a very terrible one. Where catgut is employed, as it generally is, because it is absorbed by the tissues, obviously the interior of the catgut must be as sterile as the exterior; and digestion methods in the bacteriological laboratory afford the only means of checking this. When delayed absorption is the aim the surgeon should satisfy himself that the 20, 40, and 60-day catgut is really absorbed within a few days of the time specified on the containers.

A REMEDY FOR VAGINAL INFECTIONS

DEVEGAN is the manufacturers' name for a combination of 4-oxy-3-acetyl-amino-phenyl-arsinic acid with boric acid in a carbohydrate vehicle. The arsenical constituent is, therefore, identical with the arsenical derivatives, Stovarsol, Spirocid, and Orarsan, which are widely used in the oral therapy of syphilis. The compound is made in the form of tablets for insertion into the vagina and for some time has been available to the medical profession in this country. The advantages claimed by German writers are that it causes vaginal discharges—particularly those associated with the flagellate protozoön *Trichomonas vaginalis*—to diminish in satisfactory and often remarkable fashion; and that much inconvenience and expense are saved to patients owing to the ease with which self-treatment can be carried out. The unpleasant and sometimes harmful practice of regular vaginal douching can thus be dispensed with.

It is inevitable that a new preparation which is relatively inexpensive and easy of application and produces a fair proportion of excellent results should be employed somewhat indiscriminately when its advantages are first appreciated. Accordingly, it is useful to have Hauptstein's¹ review of results in 185 cases of vaginal discharge treated with devegan at the gynaecological clinic of the University of Freiburg (Breisgau) during 1933-34. By far the best results, he says, were obtained in those whom it was possible to treat as in-patients; among out-patients the results were less encouraging, while the effects of self-treatment at home were regarded as quite unsatisfactory—a result attributed to lack of coöperation. As many as 48 per cent. of this last group failed to remain under observation and it was decided not to proceed with the investigation in this series. Among in-patients, the procedure adopted varied according to the severity of the infection and the amount of discharge. All self-douching was prohibited. Where conspicuous inflammatory changes of the vagina wall were noted the earlier insertions of devegan were preceded by vaginal douche of silver nitrate 3-5 per cent. or 1 per cent. corrosive sublimate, or both, and this was continued until the local condition showed improvement. One to four tablets of devegan were inserted high in the vaginal fornices, at first twice daily (if this was considered necessary), and then at lengthening intervals until finally the treatment was given just after the menstrual periods only. In more than two-thirds of the cases the desired result was produced within two weeks to two months. Some patients complained of the thick unpleasant discharge of unaltered masses of devegan, but this difficulty was overcome by the insertion of vaginal plugs of cotton-

¹ Clock, R. O.; Surg., Gyn., and Obst., 1934, lix., 899.

¹ Hauptstein, P.; Med. Welt., Dec. 21st, 1935, p. 1845.

wool, which the patients themselves could remove after 24–36 hours. The criteria of success were the absence of recurrence of discharge long after discontinuance of the treatment, the absence of the trichomonas flagellate on microscopic examination of the vaginal secretion after menstruation, and the presence of normal vaginal flora including the lactic acid bacillus. Impressions of the treatment were definitely favourable, both in trichomonas infections and those which were believed to be non-specific. Complete disappearance of discharge or substantial improvement occurred in all but a small proportion of cases (about 8 per cent. of the trichomonas infections and about 4 per cent. of the non-specific). Hauptstein regards the results as definitely superior to those obtained with the various antiseptic douches formerly in vogue, and he puts down relapses and partial failures to irregular attendances or indiscretions on the part of the patients, though the possibility of residual infection in urethra, rectum, or uterus, causing reinfection, is mentioned. A small number of patients showed toxic symptoms which were believed to be the result of the treatment: in 1 case there was nausea, in 9 there was local discomfort or pain of an itching and burning type, and in 1 there was œdema of the labia.

In this survey no mention is made of gonococcal infections, and it should be emphasised that there is as yet no evidence that devegan is effective in eradicating the gonococcus from its usual haunts. The practice of applying this treatment before full investigation to exclude gonococcal infection has been carried out must be condemned unreservedly, since it is likely to make the subsequent isolation of the causative organism difficult or impossible. Moreover, it should be noted that the method of self-treatment is usually unsatisfactory, even where the coöperation of the patient is assured, because of the mechanical difficulty of placing the tablets high in the vaginal fornices. Dr. Collis,² who reports from Birmingham that all but 7 of 47 patients were clear of trichomonas infection after three months—and 5 of the 7 had an associated gonorrhœa—points out that “all the patients were treated at the clinic as it was found that the tablets were more effectively inserted by an experienced person.”

ANÆSTHETICS IN THORACIC SURGERY

Nor many years ago lobectomy was a rare operation only to be witnessed at special chest hospitals. It is now a commonplace in these institutions and is likely before long to be included in the routine list of operations performed at large general hospitals. In an address to the section of anæsthetics of the Royal Society of Medicine on Feb. 7th Dr. I. W. Magill commented on the diversity of methods of securing anæsthesia for this operation. His own preference appears to be for cyclopropane, although this is admittedly contra-indicated when diathermy is used, and for spinal analgesia, the advantage of which according to Dr. Magill is becoming more and more obvious in thoracic surgery. The fear that respiratory paralysis may supervene when spinal anæsthesia is administered to patients with already limited respiratory capacity is apparently not confirmed by clinical experience. No doubt, said Dr. Magill, the explanation lies in the fact that the motor roots are so much less affected by the injection than the sensory that good analgesia is obtainable without corresponding depression of respiratory

movement. This explanation was accepted by Dr. Langton Hewer, who in the course of the discussion voiced his general preference for nitrous oxide and oxygen which does not, he claimed, imply cyanosis. He recommends in severe chest operations the early insertion of a rectal tube through which glucose should be given towards the close of the operation. Dr. Magill disapproves of premedication by any drugs with prolonged action. He employs some of the barbiturates, which are quickly metabolised, and believes that one will still be discovered better than any yet available. In many of the thoracic operations it is necessary to employ suction of the bronchi in association with intubation, and it is often a great advantage to block off other portions of the lung. He showed an ingenious apparatus which he has devised and uses for this purpose. Mr. J. E. H. Roberts thought that diathermy was almost essential in lobectomy and precluded the use of any inflammable anæsthetic. He did not like nasal intubation, and he drew attention to the very small amount of lung with which respiration could be effectively performed. Mr. H. P. Nelson likes cyclopropane for the quiet respiration it secures in the patient, but a disadvantage is that it increases the bleeding. In his view cyclopropane seems to lead the field for mediastinal dissections.

FOR THOSE ABOUT TO MARRY

THE scheme for voluntary prenuptial health examinations issued by the Eugenics Society this week¹ is constructed on such a broad foundation that it may well develop into a service of national importance. The scheme differs from those established in certain European countries in many respects, of which the most important is that it is designed only for those who themselves seek information and advice before contemplating marriage and indeed could not be worked on a compulsory basis. Moreover, the examination is not intended solely to serve the purpose of preventing dysgenic marriages or of checking the fertility of undesirable stocks—it has the further aim of improving the prospects of a successful and happy marriage. The distinguishing features of the scheme are that the applicant deals only with a doctor of his choice, through whom alone he can receive the schedules to be filled up. If the doctor is in doubt about the significance to be attached to the answers to the questions, or to his own findings on physical examination, he can seek the opinion of a consultant; or if it is a problem of heredity that puzzles him the Eugenics Society will be prepared to help in its solution through the good offices of a board of specialists. It is recognised that some doctors who are especially interested in the subject will have formulated their own questions and methods of physical examination. But in view of the infrequency of the demand hitherto it is likely that others may have little experience of such examinations and may be glad to use the pattern of premarital health schedule here provided.

It consists of three parts of which the first relates to the applicant's family history—notably consanguinity of proposed partners, the ages and causes of death of near relatives, and, more important, the incidence in near and distant relatives of diseases and defects (specified) which are thought to be hereditary. The second part of the schedule is divided into three sections, A, B, and C, in which questions are asked about (A) physical diseases, (B) psychological abnormalities, and (C) sexual

² Collis, J. L.: Jour. Obst. and Gyn. Brit. Emp., February, 1936, p. 87.

¹ Obtainable from the general secretary of the society at 69, Eccleston-square, London, S.W.1.

problems. The questions on physical diseases have been framed in accordance with the experience of insurance companies; those on possible nervous troubles bear the stamp of wise psychological advice; while the third section is skillfully planned to enable the applicant to indicate the sexual problems preoccupying him by the simple deletion of the words yes or no in answer to non-committal questions. These questions should cause little or no embarrassment to those who, having become engaged, develop anxiety about their future sex life which makes them highly sensitive to any direct attempt to probe their difficulties. A quiet chat some time after they have said "yes" to any such general question as whether the subject of sex is at all repugnant or whether there are any worries about past or future sex life that they would like to discuss, is likely to do much to reassure them. The third part of the schedule—giving space for results of physical examination—is in the form of leaves that can be used separately and should be retained by the doctor, with some confidential notes for his guidance. He is reminded that among the reasons for which a health examination may be sought before marriage are: the anxiety of parents; misgivings about hereditary diseases or defects; present abnormalities such as heart disease, glycosuria, and so forth; past diseases, often venereal; desire for specific reassurance of a general nature; and desire to break an engagement. Most doctors have had experience of the neurotic who develops ailments which serve the purpose of postponing a marriage which is not really desired. A man has even been known to ask to be examined and to draw attention to some real or imaginary disability in order to get out of an action for breach of promise.

It is clear that the Eugenics Society in issuing these schedules is in no way trying to override the functions of the practitioner, who is in fact made the central agency through whom they will be distributed. The society will not communicate with individual applicants and indeed will come into the picture only when its help is needed on a genetic problem. We believe that family doctors who have not hitherto given much attention to these problems will welcome assistance in dealing with them.

THE ACTION OF POSTERIOR PITUITARY ON THE COLON

In 1909 the late Prof. Blair-Bell observed violent peristalsis and expulsion of faeces in rabbits after pituitary extract had been injected intravenously, and recommended its use in man in conditions of intestinal stasis. It has since been widely employed in clinical practice. Further observations on animals, however, threw doubt on its power of increasing intestinal movements, and in the intact unanaesthetised dog it seems clear that movements are inhibited.¹ Since the separation of pituitary extract into "pitressin" and "pitocin" it has been suggested that many of these discordant results may be due to a difference in the actions of the two principles on different animals. In this connexion observations on the action of pitressin and pitocin on the human colon are of especial interest. Macdonald and Settle² have recently studied the action of the separated principles by inserting a balloon into the proximal colon of patients with colostomies. Intra-

venous injection of 1–2 units of pitressin were found to produce peristalsis in 2–3 minutes, usually accompanied by loss of faeces or flatus. Pitocin was usually ineffective, but it did not inhibit the action of pitressin as it does in dogs.³ Similar results were obtained when the drugs were given while X ray examinations were being made. It is noteworthy that subcutaneous or intramuscular administration of pitressin gave a response which was always delayed, and often feeble in intensity, and this raises a point of practical importance. Pitressin has been shown to cause constriction of the coronary vessels,⁴ and if administered indiscriminately might well give rise to dangerous reactions. On the other hand experience seems to show that pituitary extract given intramuscularly is usually clinically satisfactory in the treatment of post-operative intestinal distension, or where it is desired to remove gas from the colon preparatory to X ray examination of the renal tract. It would nevertheless be of interest if alternative drugs for this purpose, such as eserine,⁵ Prostigmin,⁶ prostigmin plus pituitrin,⁶ or acetylcholine⁷ were more widely used and reported upon, so that their relative merits could be more fully assessed.

Sir Thomas Barlow has been elected a member of the French Academy of Medicine.

THERE is universal sympathy with Sir Humphry and Lady Rolleston in the tragic death of their only remaining son during an *émeute* in Zanzibar. The feeling will be specially present in the medical profession, where Sir Humphry Rolleston, in private as well as in many important public positions, is regarded with such real respect and affection.

ON Feb. 17th and 26th and March 2nd the Lettsomian lectures of the Medical Society of London will be delivered by Dr. Philip Manson-Bahr in the Society's house in Chandos-street at 9 P.M. He will speak on the differential diagnosis of diseases of the colon (dysentery and colitis) and their complications.

Sir Herbert Cooke, whose death occurred on Feb. 6th in St. George's Hospital as the result of an accident, was a distinguished soldier with a great Indian record behind him. Also he was a practical philanthropist and a worker in an important medical cause. Retired as a lieutenant-general while still comparatively young and full of energy, he adopted as a hobby the London Children's Gardens Fund and during his connexion with the movement secured a greatly increased support for the valuable project of securing for London's poorest slum children the joy of possessing a garden, and in this work he found the health of the children an efficient argument for soliciting support. Recently he had taken charge of the activities for securing the money for the rebuilding of St. George's Hospital, and his work had already borne fruit, the results of his capacity and ingenuity in planning becoming evident. He regarded that work as only initial to larger developments, and his sudden death is a great loss to a charitable cause into which he had thrown himself with enthusiasm.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXXVIII.—PROGNOSIS OF FRACTURES OF THE UPPER END OF THE FEMUR

FRACTURE of the upper end of the femur is frequently followed, within a few weeks or months, by the death of the patient. Of 615 patients who were admitted during twenty years to Lambeth Hospital 166 died without leaving the hospital, and of the remainder a large number were left with a disability that materially reduced their enjoyment of life. This high mortality and grave disability is, however, not so much due to the injury itself as to the fact that it is an injury that occurs much more frequently among the old than the young, among the feeble than the strong. The average age of the patients mentioned above was 69 years, and in many cases the fracture was an incident in their final illness, hastening the end little, if at all.

Factors to be Considered

In giving a prognosis in any particular case several factors must be considered.

AGE OF THE PATIENT

The older the patient the more chance there is of death occurring directly as a result of the injury. Old people are much less able to put up with the discomforts attendant upon the treatment of even minor injuries than are the young, and any attempt to submit them to an unpleasant régime may bring about fatal complications.

CARDIOVASCULAR DISEASE

A large number of patients who sustain this injury are suffering from cardiovascular disease, and many of them have had a cerebral thrombosis or other disabling complication. Indeed the reason why this fracture mainly occurs late in life is because it can only happen when bones have been rendered brittle and muscles have lost their tone. It is for this reason that the mortality of the injury is so high. In this connexion it is interesting to note that there are two different periods after the fracture at which death tends to occur in feeble patients: (1) those who die within about fourteen days, being unable to adapt themselves to the altered circumstances which the injury produces; and (2) those who live for eight or ten weeks and make an apparent recovery only to die when the first attempt is made to get them out of bed. In the latter group are patients whose hearts are only strong enough to keep them alive when at rest and are unable to stand the strain of movement. A large proportion of patients who die after this injury fall into this second class.

SITUATION OF THE FRACTURE

For the purposes of prognosis only three situations need be considered: (a) fracture through the neck; (b) fracture through the great trochanter; (c) fracture immediately below both trochanters. As regards mortality there is little difference between these three situations. Among the above-mentioned 615 patients, 24.5 per cent. of the fractures of the neck, 29.3 per cent. of the fractures through the great trochanter, and 25 per cent. of the sub-trochanteric fractures died without leaving hospital, but there is a great difference between the prognosis of the three types in regard to functional results.

Fractures through the neck, when they occur in young people or in people who are healthy enough to undergo severe operations or prolonged and trying treatment, have a very good chance of getting bony union in moderately satisfactory positions and of being restored to almost full functional use of the limb. Treatment by a Whitman's plaster without open operation but with manipulation under an anæsthetic, or by the insertion of a Smith-Petersen's pin, the position of the fragments being determined by open operation, both give good results in the hands of experienced workers. It is probable that Whitman's method is applicable to a larger number of patients but Smith-Petersen's pin shortens somewhat the time during which treatment is necessary. For those who are unable to stand either of these methods of treatment a strong fibrous union can generally be secured by fixing the patient on an extension frame with both lower limbs suspended and widely abducted. If this position be retained, without interruption, for ten weeks a firm fibrous union will form and the patient can then walk about with the help of a calliper splint, which should be worn for a period of one or two years. Movements of the hip in these patients with fibrous union are generally painless over a very small range of movement, but cause pain when the patient is fatigued or when any extended range of movement is attempted.

Fractures through the great trochanter, while having the same mortality as fractures of the neck for reasons given above, should cause very much less disability if they are properly treated. They practically never fail to join firmly by bony union, and if properly disimpacted and placed in good position in an extension frame with both legs abducted the union will generally be firm in eight weeks, and the patient afterwards will walk with but little disability. If the fracture is firmly impacted and the patient is very feeble it is sometimes tempting to allow the impaction to remain, with the bones in bad position, and to let the patient walk about as best he can within two or three weeks of the fracture. Such a method is sometimes, though rarely, successful; more often the patient's disability is so great that his feebleness is increased by the added effort of moving with a deformed limb. It is probably always better to disimpact if it is at all possible to give the patient an anæsthetic. The operation should never be done without an anæsthetic.

Sub-trochanteric fractures occur in patients whose bones are unusually brittle, and frequently in those bones which are the seat of neoplasm. The prognosis in this case is that of the disease and not of the fracture.

THE TIME WHEN TREATMENT IS FIRST APPLIED

To get the best results in fractures of the femur the patient must be cared for by skilled nurses with experience in this class of injury. Unless steps are taken to reduce deformity, and to secure such apposition of the fragments as is possible, within about forty-eight hours of the fracture, there is little likelihood of a good result being obtained. During the first two or three days after the fracture there is a great danger that the feeble patient may be worn out by pain and acquire bedsores, thus preventing subsequent effective treatment. It is surprising with what rapidity bedsores may form during the

first few hours in these cases, and the best way to prevent them is to apply, as a first aid, a simple axial extension by means of a Buck's stirrup to both legs and to place them on a frame by a counterpoise, thus lifting part of the weight of the helpless limbs off the bed. The practice of placing the damaged limb between sandbags as a first-aid measure cannot be too strongly condemned; the only effect of such sandbags is to make sure that any movement of the

patient's body, occurring while the leg is held still, will take place at the site of the fracture, causing pain to the patient and further laceration of the damaged tissues, and materially lessening the prospect of a satisfactory recovery.

TEA AND COFFEE

A PHARMACOLOGICAL DISCUSSION

At a combined meeting of the Society of Public Analysts and other Analytical Chemists with the Society of Chemical Industry (Food Group), held at the Chemical Societies Rooms, Burlington House, Piccadilly, on Feb. 5th, the chair being occupied by Mr. JOHN EVANS, M.Sc., F.I.C., president of the first-named society, a discussion on tea and coffee, with special reference to their tannins and alkaloid, was opened by Dr. G. ROCHE LYNCH, analyst to the Home Office. It was, he said, generally assumed that the pharmacology of tea and coffee could be stated in terms of caffeine—which he very much doubted. He understood it to be agreed that tea contained, on the average, $2\frac{1}{2}$ – $4\frac{1}{2}$ per cent. of caffeine, and coffee 0.5–1.5 per cent. of caffeine. The action of caffeine on the body could be divided into three groups: its effect on the central nervous system, its action on muscular tissue (including heart muscle and that controlling the intestines), and its diuretic action or promotion of the flow of urine.

THREEFOLD ACTION OF CAFFEINE

The action of caffeine on the *central nervous system* was almost entirely in the form of a psychological function, i.e., on the higher centres of the brain. If it were taken in toxic doses, it might exert an effect on the spinal cord similar to that of strychnine, namely, in producing convulsions. In the course of its action on the central nervous system caffeine facilitated the perception of sensory stimuli and the association of ideas, so that consciousness became, under its influence, more acute. One of the results of that was a condition of wakefulness or increased alertness, and so any tendency to drowsiness or fatigue was made to disappear or was much less pronounced. A corollary to this was that interpretations of sensory stimuli received by the brain from various external sources became more perfect and accurate. Even more important was the fact that these stimuli were correctly placed in relation to each other. In this latter respect there was a profound difference between the effect of caffeine and that of cocaine, for in the case of the latter, in addition to the increased perception of the higher centres, enhanced impressions from the lower centres were also received, and the impressions were not so perfect as in the case of caffeine. Thus with cocaine the tendency was for the judgment to be impaired; with caffeine the accuracy of the judgment was enhanced. Caffeine also caused a constriction of the musculature of the blood-vessels, leading to a rise in blood pressure, and respiration was stimulated. The centres controlling these functions were situated in the lower part of the brain, and that

was an additional fact in the pharmacology of caffeine. If a person took a very large dose of caffeine, the process just described was intensified, and the result was a confusion of thought, and disorders of sensation, which were associated with flashes of light in the eyes and noises in the ears, so-called tinnitus. If extreme doses were given, this excitation proceeded to restlessness and the receiver became tremulous, and might develop convulsions, as followed strychnine poisoning.

With regard to the action on *muscle tissue*, he reminded his hearers that from the medical point of view muscle was divided into three kinds: voluntary muscle, the working of which was controlled by the will; cardiac muscle, a specialised form; and the involuntary muscle, such as that in the intestines and the blood-vessels, not under the immediate control of the will. Although not definitely known, it was believed that caffeine acted directly on the muscle-cells, not on the nerve-cells; and the muscular work performed by the person taking caffeine could be increased without that person feeling fatigued in corresponding degree. Here arose a difficulty, as it was impossible to say whether or not the abolition of the feeling of fatigue was due to an effect of the drug on the muscles or on the central nervous system. As would be expected from what he had said, caffeine was a factor in producing contraction of blood-vessels and intestines, and their more vigorous action. There occurred also in those who had taken caffeine a general acceleration of the heart beat, with a diminution of the diastolic period; hence if the dose were large over a period of time the effect on the heart might be definitely unfavourable. In ordinary medicinal doses, however, the taking of caffeine seemed to have no deleterious effect. The cardiac state after taking large doses of the drug may take the form of auricular fibrillation. Conceivably this might lead to death, though actually death from caffeine is very rare.

With regard to the *diuretic action* of caffeine, the increased flow of urine promoted by it was due to a greater output of water, so that the urine itself became more dilute than normal; but tested over an appreciable period, there was found to be, not only an increase in the total urinary output, but also in the total solids passed. This elimination of water was among the valuable results of the medicinal use of caffeine, as seen in patients who were suffering from dropsy, hence the special value of the drug in heart failure or of kidney disease. This increased elimination of water was found to be partly due to the raised blood pressure, and partly to the specific action of the caffeine on the cells of the kidney, enabling them to excrete water and, to some extent, solids too, in greater amount. Some of the caffeine is decomposed in the body, some excreted in the urine in an unchanged condition, and some in a partly de-methylated form, i.e., mono- or di-methyl xanthine (caffeine is trimethyl xanthine).

OVERDOSE. ADDICTION. SLEEPLESSNESS

Dr. Roche Lynch said he had not yet encountered a case in which death was definitely caused by an overdose of caffeine. As much as grs. 60 of the drug had been taken at a time, but the serious illness which immediately resulted was recovered from. After taking very large doses of caffeine the person manifested the form of excitation which may be seen in people drunk from alcohol; dizziness, a ringing and buzzing in the ears, trembling, sleeplessness, confusion of ideas, delirium, palpitation of the heart, and even strychnine-like convulsions.

He did not consider that caffeine could be included in the drugs which came under the heading of addiction. People who took it in the form of coffee and tea became accustomed to it, and as they looked forward to it and liked it they found it difficult to do without it. Still, as opposed to the case of cocaine and morphine, it could be given up without much mental effort or feeling of loss, and its indulgence did not cause the serious train of symptoms which followed the habitual taking of cocaine and morphine. In post-mortem examinations he did not believe that any changes in the stomach and intestines occurred in those who had drunk largely of the beverages tea and coffee that could be associated with such drinking. He knew of no cases warranting the suggestion that either caffeine or the tannin could produce such an effect.

With regard to sleeplessness, he felt himself to be in somewhat of a difficulty, and he invited suggestions. All must know people who said they dare not take coffee after dinner, as it would keep them awake half the night; some said they always took a cup of tea instead, while others said that if they wished to do writing late at night this was made easier by taking a cup of tea. On the other hand, when people had narcotic poisoning, coffee administered per rectum was a common remedy employed. That the association of these beverages and sleeplessness may be largely psychical was suggested by the fact that in many cases if one gave caffeine citrate in a medicine unknown to the patient, there was often no interference with his sleep. Though he had pointed out various attributes of caffeine, such as increased stimulation, he felt there must be some further factor in the beverages under discussion which had definite effects in regard to sleep, but which at present could only be conjectured.

TANNIN IN TEA

In a paper on the tannin-content of tea, by Mr. P. J. NORMAN, F.I.C., and Mr. E. B. HUGHES, D.Sc., F.I.C., the authors referred to the lack of knowledge of the exact nature of tea-tannin, and for this reason they had made comparative extractions of tea-tannin by the more important of the methods employed. They pointed out that tannin is present in all tea, that it is an important constituent in that it contributes largely to those properties which characterise the quality of tea, and that there is more tannin in good leaf than in poor leaf and less in stalk than in leaf. The methods used for the comparative analyses were:—

1. Cinchonine precipitation of the tannin;
2. The Löwenthal method of oxidation of the tannin by potassium permanganate; and
3. The hide-powder method.

Results obtained showed that teas of the same class could be compared, as regards tannin-content, by any one of these methods, but that there was some difference in results by the three methods for any one tea, this depending on whether the tea was a

black (fully fermented) tea such as Indian, Ceylon, China, &c., or a green (unfermented) tea (little drunk in this country), or Oolong (lightly fermented) tea. There was also some difference among black (Indian and Ceylon) teas which the authors considered to be due to the grading (by fineness) of the tea. Results were given for a large number of unblended teas of known origin, varying from 10 to 17 per cent. of the dry tea for black teas, and 9 to 15 per cent. for green and Oolong teas. The authors had also determined the tannin-content of a number of teas sold to the public as "digestive," "invalid," &c., teas; these were found to have the same tannin-content as the ordinary commercial teas of the same class (black teas of Indian, Ceylon, China, &c.). It was pointed out that infusions of tea, as ordinarily prepared for drinking, contain about two-thirds of the tannin from Indian or Ceylon tea and about one-half of the tannin from China tea.

COFFEE EXTRACT

Mr. EDWARD HINKS, B.Sc., F.I.C., read a paper on coffee extracts. A considerable proportion of the fluid consumed in this country as coffee must, he said, be reconstituted from coffee extract. The proper criterion of the value of an extract was, he thought, that its composition when reformed or reconstituted should be as close as possible to that obtained from the native article, a parallel case being condensed or dried milk in comparison with liquid cow's milk; the loss should be only that inseparable from the processes of drying or condensing. His experience was that extracts purporting to be pure coffee were comparatively rare, coffee and chicory extracts being the commoner. But judging from the samples he had received the caffeine in the two classes did not differ much, the coffee extracts (12 in number) containing from 0.1 to 0.33 per cent. of caffeine (average 0.21), and the 45 coffee and chicory extracts containing from 0.05 to 0.38 per cent. (average 0.19), though there might be some doubt about the designation of some of the coffee extracts. A dry extract he had examined contained 6.8 per cent. of caffeine. Taking the caffeine as a basis of evaluation, the poorest extracts gave a "coffee" only of from one-tenth to one-fifth the strength of ordinary breakfast coffee made from the berry and even at the best they were but a poor approach to the real article. Why then did these beverages look so much like coffee? It appeared to be due to the use of caramel. A comparison of the costs, again on the basis of caffeine, gave some humorous results. In pure coffee at 2s. 6d. per lb. a "unit" of caffeine cost 7d.; in the dry extract it was 6.2d.; in a "0.22 per cent." coffee extract it was 28d., and in a "0.1 per cent." coffee and chicory extract it was found to be 41d.

UNSUPPORTED CLAIMS

Mr. AINSWORTH MITCHELL, D.Sc., F.I.C., read a communication from Mr. H. H. BAGNALL, B.Sc., F.I.C., city analyst of Birmingham, in which he spoke of the results of his analyses of a number of packet teas whose wrappers bore various claims, mainly in the direction of preventing or curing digestive disorders because of the absence from the teas of tannin. In every case those claims were unsupported by scientific fact. In the alleged tannin-free teas he found from 9.9 to 16.4 per cent. of tannin, the average of a series being 12.5 per cent. Two China teas contained 8.6 per cent. of tannin. One brand of tea was stated to contain only the tips of leaves and therefore to be tanninless; it had the average quantity of tannin and was ground fine to give the

idea of tips. One brand was stated to be curative because of the large vitamin content, but it had only a trace of one vitamin—namely, E. In many cases a representation to the firms of the error in the claims made resulted in modification of the wording on the packets.

Mr. A. L. BACHARACH, M.A., F.I.C., asked whether caffeine could be regarded as a cumulative poison, and if so, was it cumulative because it was stored and then gradually used by the body, or because its adverse effect on certain organs continued for a considerable time?

Mr. H. H. MANN, D.Sc., F.I.C., assistant director of the Woburn Experimental Station, remarking that he had been connected with the tea industry for 36 years, said there was no relationship between the price paid for tea and its caffeine content. Other things being equal, teas of high tannin-content were generally superior. Taste was an important factor in the choice of teas, and he thought an investigation should be made into the different forms of tannin which tea contained before dogmatic statements could be made about its effect on quality.

Mr. L. H. LAMPITT, D.Sc., F.I.C., agreed with Dr. Mann about the importance of taste. In making claims that their teas were tannin-free the proprietors of some packet teas were no doubt playing up to the public imagination of tanning the stomach. Dr. Roche Lynch, he recalled, could find no post-mortem evidence of stomach tanning.

Dr. ROCHE LYNCH, in a brief reply, said that any cumulative effect of caffeine might have been not from storage, as it was quickly broken down in the body.

VIENNA

(FROM OUR OWN CORRESPONDENT)

DEATHS IN THE PROFESSION

THE University of Vienna has had a serious loss in the deaths of Prof. Maresch and Prof. Bruno Busson. The former, who died of bronchial cancer at the age of 68, first worked at the institutes of anatomy and pathology in Prague. When he came to Vienna he began to study surgery and gynaecology but he soon forsook them for morbid anatomy. He was chief pathologist at the Rudolfs-spital and also in the Municipal Hospital. He was appointed a lecturer by the university in 1910 and in 1923 succeeded Paltauf in the chair of morbid anatomy, which he held till his death. His early work was on the epithelial bodies and the histology of the kidney, and his staining methods were unique; he devoted his later researches to the problems of the internal secretions. His institute contains a splendid museum which is chiefly the result of his own work. He was an excellent teacher, and as an authority on morbid anatomy his reputation was international. Busson was director of the federal Serotherapeutic Institute, which controls all the vaccines and sera used in Austria. He graduated here and studied hygiene and bacteriology in Graz and Paris. During the late war he was in charge of the Health Commission and was responsible for the comparative freedom from war epidemics at the front and in the hinterland. His work was mainly concerned with immunity and experimental medicine especially with tetanus and diphtheria.

THE FIRST AID SOCIETY IN 1935

The ambulance corps here, which served as a model for the others in Europe, has dealt in the past

year with 26,134 emergencies, an average of 72 daily. The proportion of injuries to sudden illness, three to two, has remained constant for about eight years. There were 3112 traffic accidents; 1775 of these were due to motor-cars, 757 to pedal cycles, 419 to tramcars, 111 to horse-driven vehicles, and 50 to railway accidents. Sport and athletics were responsible for 725 casualties, 414 persons were bitten by animals, and 1685 were injured in factories. Members of the society also attended 391 women in precipitate labour, 2000 cases of suicide and attempted suicide, 230 of insanity, and 180 of alcoholic excess. The close co-operation of police and hospital staffs with the society ensures an immediate response to emergency; 15 lives, for example, were saved by this efficiency after injuries to the heart by stabbing or shooting; while the patient is being hurried to hospital in an ambulance the surgical staff have already been warned and are prepared to operate at once.

CORONARY OCCLUSION

Dr. N. Landau has recently been speaking on the pathology and treatment of cardiac infarct. In the Vienna Heart Hospital there have been in the last three years 150 cases of sudden coronary occlusion; 80 per cent. of the patients were men, 45 per cent. were aged 55-65, and 30 per cent. aged 45-55; but 8 per cent. were not yet 45 and 2.5 per cent. were under 40. The majority (78 per cent.) had some previous symptoms such as dyspnoea, vertigo, intermittent claudication, or those of hypertension. In 21 per cent. the precise time of onset could not be determined, and neither exercise nor the time of the day seemed to have any influence. The majority had had angina pectoris for about five years but in 4 per cent. it was entirely absent; other symptoms were cold sweats (25 per cent.), dyspnoea (25 per cent.), angor animi (18 per cent.), nausea and vomiting (15 per cent.), and unconsciousness (10 per cent.). In 91 patients brought in with a recent infarct the clinical findings were few; 60 per cent. had weak murmurs, while of the 23 that had a gallop rhythm only 7 survived. An important sign almost constant enough to be considered pathognomonic was a rise of 1-3° C. in the rectal temperature, present in 75 per cent. and remaining for about a month in 30 per cent. Blood pressure was low in 60 per cent. and remained so for several weeks. A tachycardia not affected by digitalis was a bad sign. The electrocardiogram was always abnormal; in 83 per cent. it was characteristic of occlusion of a coronary branch and in 17 per cent. of myocarditis. The mortality was 30 per cent., of whom a third died suddenly, some even in convalescence; the rest died after getting progressively weaker in spite of all treatment.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

TREATMENT OF LUPUS VULGARIS

Dr. Robert Aitken, at last week's meeting of the Edinburgh Medico-Chirurgical Society, reported strikingly good results in the treatment of lupus vulgaris by the use of the Finsen-Lomholt lamp. In the past five years, he said, 0.6 to 1 per cent. of the new cases seen in the skin department of the Royal Infirmary of Edinburgh were cases of lupus vulgaris; fifteen years ago the incidence of this disease was three times as great. He has investigated 310 patients and the face was affected in 77 per cent. of them.

In more than half, the disease began during school life, and it is uncommon for it to commence after middle age. He stressed the frequency with which this condition is associated with tuberculous glands, and said that during the past seven years 116 cases of lupus with tuberculous adenitis were treated at his department. Until recently lupus has been a very intractable disease, and the results of the old forms of treatment were often unsightly. Dr. Aitken condemned, in particular, the end-results of X ray treatment, for the scar of the burn is disfiguring and it often stimulates the development of carcinoma. In his opinion the diminishing incidence of lupus is due to the successful treatment of tuberculous glands with general light baths, without which many would have developed lupus at a later age. The general treatment of lupus necessitates the use of the hygienic and dietetic measures that apply to the treatment of all forms of tuberculosis. Tuberculin is the remedy of choice in the absence of facilities for light treatment. Excision, scraping, and cauterising are all unsatisfactory, and they fail to remove the disease from the deep skin glands; X ray treatment should also be given up. The original Finsen light treatment was satisfactory up to a point, but whereas only 15 per cent. of the radiation energy of this lamp could be applied to the diseased surface the corresponding figures for the new Finsen-Lombolt lamp is 70 per cent. This increase in power has enabled the time required for each treatment to be reduced to no more than one hour, and its convenient construction makes the application much less tiring for the nurse in charge.

Dr. Aitken showed a number of beautiful coloured slides showing that even in an advanced state the disease could usually be cured in about six months. Reports of a large series treated in Vienna from 1914 to 1923 show that the striking results are usually permanent.

GLASGOW ROYAL INFIRMARY

In the 141st annual report of the managers of Glasgow Royal Infirmary it is stated that there were over 18,000 in-patients and 120,000 out-patients during the past year. There has been a deficit on the ordinary account of over £26,000; the extraordinary receipts totalled £62,000, and it was possible to carry £28,000 of this to the capital account. The managers hope that the Canniesburn auxiliary scheme, the foundation-stone of which was laid by the Duke of Kent in May of last year, will be completed by the end of 1936. These buildings will provide 80 beds for patients in early stages of convalescence, together with 40 beds for paying patients of limited means. It is hoped that the provision of these additional buildings will reduce the number of patients awaiting admission to the infirmary.

THE LATE PROF. ASHWORTH

Edinburgh graduates who have enjoyed his teaching will feel that the university has lost one of its outstanding figures by the sudden death of Prof. James Hartley Ashworth, F.R.S., of the chair of natural history. It was because of his important work in invertebrate zoology that large contributions were made to the university for building the new zoological laboratories. He was particularly interested in entomology and protozoology and had conducted a class in this subject in the university since 1905. His life and energies were devoted to his science and to the university, in which he taught for nearly thirty-six years. He was everywhere popular and was always anxious to help his colleagues and his students.

IRELAND

(FROM OUR OWN CORRESPONDENTS)

THE NATIONAL MATERNITY HOSPITAL

The governors of the National Maternity Hospital, Dublin, are engaged in promoting a private Bill with the object of amending their charter, altering the name of their corporation, and effecting other changes in their powers and constitution. The preamble of the Bill has been declared proved and the Bill now lies on the table of the Dáil. The National Maternity Hospital, which is familiarly known as Holles-street Hospital, was founded in 1894 for the relief of poor lying-in women and for the treatment of diseases peculiar to women. In 1903 a charter under the Great Seal of Ireland was issued by King Edward VII., which established the corporation of governors of the hospital, and defined their powers and duties. The hospital has had a very successful career, and having outgrown its old premises, has recently been provided with a new and commodious building from Sweepstake Funds. Up to the present the hospital has been managed by a body of governors co-opted as vacancies occurred. It is now proposed to make several important changes in the constitution, and to bring the hospital into direct relation on the one hand with University College, Dublin; and on the other with certain general clinical hospitals. At present the number of governors is limited to 65, but if the Bill becomes law this limit will be raised to 100. Of these governors 3 shall be nominated by the corporation of Dublin, 2 shall be nominated by the governing body of University College, Dublin, and 1 each shall be elected by the hospital from the staffs of Jervis-street Hospital, the Mater Misericordiæ Hospital, and St. Vincent's Hospital respectively. Provision is made for the appointment of an executive committee and the delegation to it of certain powers. The hospital is to be designated in future "The National Hospital for Women, Dublin." It is provided that the present master (Dr. J. F. Cunningham) shall continue in office until Dec. 31st, 1941.

THE KING'S PROFESSORSHIPS IN THE SCHOOL OF PHYSIC

On Feb. 7th the President and Fellows of the Royal College of Physicians of Ireland elected Dr. David Smyth Torrens to the King's professorship of the institutes of medicine in the School of Physic, Trinity College, Dublin, to fill the vacancy created by the death of Prof. Harold Pringle. Dr. Torrens has been for some time assistant professor of physiology in Trinity College. He was formerly lecturer in zoology in the Royal College of Science, Dublin. At the same meeting the resignation of Dr. Thomas Henry Wilson, King's professor of midwifery since 1910, was received with regret. Dr. Wilson's health has not been good in recent months.

OUTBREAK OF FIRE AT QUEEN'S UNIVERSITY, BELFAST

There was a serious fire at Queen's University, Belfast, on the afternoon of Feb. 7th. The part affected was the medical school, which is a large building situated close to others in the university grounds. The fire began in a storeroom under the anatomy lecture theatre, which is on the second floor. Students were at work in the dissecting-room nearby and on the ground floor a surgical lecture was in progress. So rapid was the spread in the few minutes before the brigade arrived that the building had to be evacuated, dense clouds of smoke pouring

from it. A strong wind was blowing and at one time it seemed as if the fire might spread to involve the whole building; but the efforts of the brigade were soon successful in confining it to the storeroom and the anatomy lecture theatre. Here the fire blazed furiously, the dry wood of the benches igniting readily, and before long flames were seen to be coming through the roof. In about an hour and a half, however, the fire was under control and subdued. It was feared at first that Prof. T. Walmsley's room

and the laboratory in the tower would have been destroyed, but we understand that, apart from damage to the roof, there has been no other serious loss. Directly beneath the fire was the museum which contained a large and valuable collection of anatomical and pathological specimens. Though part of the ceiling was damaged by the fire breaking through in one place, it did not collapse and the contents of the museum were only slightly damaged. The building is now closed and in the hands of the salvage authorities.

CORRESPONDENCE

GASTRIC ACIDITY AND ITS SIGNIFICANCE

To the Editor of THE LANCET

SIR,—Prof. Apperly's paper in your issue of Jan. 4th will have been read by many with interest, as it is both stimulating and provocative. By the time this reaches you I feel sure you that will have received letters from others who can refute from experience some of the assumptions that Prof. Apperly makes from indirect evidence. You may, however, feel that my experience, in another country, is also worth recording.

There must be a mass of evidence on record to contradict the statement that "When the former [the red cell content of the blood] falls to about half or two-thirds normal (on the average) free acid disappears from the stomach." You yourself have made a mild protest against this statement in an annotation in the same issue. I will quote only from a series of my cases that I am at the moment analysing; in a series of fractional gastric analyses on 33 Assam tea-garden coolies whose blood hæmoglobin content ranged from 17 to 45 per cent., mean 32 per cent. (100 per cent. = 13.75 grammes per 100 c.cm.), in 27 the maximum gastric acidity (free) was from 25 to 90 c.cm. of N/10 hydrochloric acid per 100 c.cm., in 2 it was 20 c.cm., in 3 there was free acid but less than 20 c.cm., and in 1 case only was there achlorhydria (histamine not given). In this last case at the beginning of treatment the hæmoglobin was 29 per cent. (4 g.), but it improved to 80 per cent. (11 g.) when a trace of free acid appeared in one sample only (1½ hours) in the fractional gastric analysis.

Though I have always accepted the view that anæmia, per se, may lead to hypochlorhydria or even achlorhydria, recent experience adds very little support to this view; I will cite two cases actually in my wards at the moment: one is a case of hyperchlorhydria (maximum 75 c.cm. N/10 HCl) with 2.75 g. of hæmoglobin (20 per cent.), and the other a case of hypochlorhydric microcytic anæmia in which, though the hæmoglobin increased from 2.47 to 16.00 g. in three months, the maximum hydrochloric acid concentration only increased from 12 to 14 c.cm.

None of our experience in this country suggests that gastric acidity is diminished in a hot climate. The normal gastric acidity is higher than that usually recorded in England and North America (Napier and Gupta: *Indian Jour. Med. Res.*, 1935, xxiii., 455). There are of course other factors to be considered, but all Indians do not live on the traditional highly spiced diet, nor is the evidence conclusive that a highly spiced diet leads to permanent hyperchlorhydria; it may lead to gastritis, the final result of which is hypochlorhydria or even achlorhydria.

Regarding the gastric acidity in asthma, there are many references in the literature (e.g., Hurst: *Brit. Med. Jour.*, 1930, i., 1138; and Bray: "Recent

Advances in Allergy," London, 1931), and it is generally claimed that the acidity is lowered; we (Dharmendra and Napier: *Indian Med. Gaz.*, 1935, lxx., 301), however, found it increased; but admittedly our cases were not true allergic asthma nor was the analysis done at the time of an attack.

I am, Sir, yours faithfully,

L. EVERARD NAPIER, M.R.C.P. Lond.,
Professor of Tropical Medicine.

School of Tropical Medicine, Calcutta, Jan. 31st.

FAMILIAL CIRRHOSIS AND TELANGIECTASIA

To the Editor of THE LANCET

SIR,—I was much interested in Dr. Parkes Weber's paper on the familial tendency to development of hepatic cirrhosis and more especially in his reference to the relationship between cirrhosis and telangiectasia of the Osler type. As Dr. Weber points out there have been many valuable papers on this disease, particularly by H. I. Goldstein, but it is remarkable how few members of the profession are familiar with the condition. In a letter to THE LANCET (1933, i., 116) Goldstein said that there are "probably recorded to date about 110 or 120 families and about 700 persons suffering from Rendu-Osler-Weber's disease (heredofamilial epistaxis with or without familial hæmorrhagic telangiectasia) in the entire available medical literature of the world." When one considers that Osler's original paper was written in 1901 (and a family showing epistaxis was described by Babington in 1865) and, further, that cases have been reported from all over the world, these figures are undoubtedly very small if they truly represent the incidence of this disease. From personal experience I have thought for some time that the figures must be fictitiously low. During the past six years I have personally observed 10 families suffering from this disease, including in their number 56 affected persons; all these people live in the West Riding of Yorkshire and as far as I have been able to trace them the families are unrelated and have not been previously recorded. The wealth of clinical material in Leeds is certainly remarkable, but it is very unlikely that about 10 per cent. of all the cases of familial telangiectasia in the world are living in the West Riding. A considerable number of my cases have shown that the profession as a whole is unfamiliar with the condition and though several of the patients have been transferred to me by Dr. J. T. Ingram, others have come as cases of anæmia of unknown origin, epistaxis, and even headache.

The association of telangiectasia with hepatic cirrhosis is of great interest and I agree with Dr. Weber that the telangiectasia is probably a congenital-developmental dysplasia of the small blood-vessels, and that the cirrhosis may be the result of associated developmental dysbiotrophy of the liver. At the same time there can be no doubt that cirrhosis is not an essential feature of this disease at any of its

stages, and I have not yet seen a patient showing any suggestion of liver disorder. There is, however, a possible relationship between familial telangiectasia and neurofibromatosis, and I have seen a family suffering from the latter condition in whom there are several affected persons also suffering from unexplained epistaxis; at the same time I have not found any definite evidence of neurofibromatosis in patients suffering from telangiectasia, although I have thought that the incidence of skin tags, patches of pigmentation, and other slight abnormalities of the skin is higher than usual in these people. If there should prove to be any relationship between hepatic cirrhosis and familial telangiectasia it is important to remember that the latter disease is recognised as being one of the most regularly inherited Mendelian dominant defects in man, and in my own large series of cases, with the exception of one or two sporadic cases of doubtful significance, I have found no exception to this rule.

I have recently satisfied myself that this condition of telangiectasia is radiosensitive and that the epistaxis can probably be cured by radium. This will prove to be important, as the disease may, and frequently does, produce completely disabling anæmia which can only be relieved when the epistaxis is arrested.—I am, Sir, yours faithfully,

Leeds, Feb. 10th.

HUGH G. GARLAND.

SODIUM MANDELATE IN CHRONIC CYSTITIS

To the Editor of THE LANCET

SIR,—A personal record of the effect of various urinary antiseptics upon chronic cystitis may be of interest to some of your readers. My catheter life began in 1932, at the age of 72, after an attack of acute retention. In spite of the most careful asepsis, the urine became infected with *B. coli* and, on the advice of a urologist, I dispensed with the use of the catheter. It was at this time that I started my experience of various urinary antiseptics, samples of urine being sent regularly for bacteriological examination to Mr. A. E. Parkes, F.I.C., public analyst for Poplar, West Ham, and Bethnal Green. I found that hexamine, citrates, bicarbonates, and sodium acetate, benzoate, and salicylate were not readily tolerated, but hexyl resorcinol and Pyridium both proved of value, the latter being very soothing to an irritable bladder. Organisms, however, were constantly present though with pyridium there were occasionally as few as 10 bacilli present per c.cm.

In November, 1935, I began a course of sodium mandelate (3.5 g.) and ammonium chloride (1 g. cachet) four times a day, restricting my fluid intake to two pints. The immediate effect of this remedy was to produce a nocturnal diuresis. Despite some thirst, anorexia, and nausea, I persisted with the treatment for 13 days, and the complete disappearance of bacteria from the urine made the discomfort worth while. Five weeks later, following exposure to cold—I went to vote—I had another attack of cystitis and of acute retention necessitating catheterisation and the infection probably recurred. Sodium mandelate was again taken on Nov. 22nd and 23rd, but this time I decided to reduce the dose of ammonium chloride to 1 × 1 g. cachet daily, and this proved sufficient to make the urine acid to methyl-red. Nevertheless, the treatment caused some strangury and after two days it was stopped. Once more, however, it must have proved capable of destroying the organisms, for a sample of urine was taken next day (Nov. 24th) and no *B. coli* could be grown from 1 c.cm. Now, 13 weeks later, though there is still two ounces of residual urine and some-

times more, necessitating catheterisation night and morning, the urine is quite clear and bright and I am comfortable and practically symptom-free. (I started catheterisation again on Nov. 17th after 15 months without passing a catheter at all.)

Mr. Parkes carried out some experiments on the mandelic acid content of the urine. From one specimen of 10 c.cm. he extracted 20 mg. of mandelic acid, which indicates a concentration of 0.2 per cent., and he was able to show that at 37° C. a 0.1 per cent. solution of pH 4 of the acid in urine was fatal to *B. coli* in one hour, though a 0.007 per cent. solution had no effect in two hours.

The chief lessons I have learnt are that 1 g. only of ammonium chloride per day is sufficient to acidify my urine, and that sodium mandelate taken for 2-3 days whenever the urine becomes cloudy clears up the infection. The comfort of having got rid of the urinary infection cannot be expressed. After I had spent a small fortune trying other remedies, sodium mandelate finally did the trick and, up to the present, has given me a new lease of life.

I am, Sir, yours faithfully,

Teddington, Feb. 9th.

F. W. ALEXANDER.

CARD PARTY FOR MEDICAL CHARITY

To the Editor of THE LANCET

SIR,—In your issue of Feb. 8th I note you have a record on p. 329 of the case *Williams v. Trevor*, but this account does not include the final statement of counsel or the remarks of the judge. Will you please insert in your next issue that statement, which was as follows:—

Sir William Jowitt said he desired to apologise for a mistake he made in opening the case. In all newspapers he was reported as having said that the card party was "for the benefit of the Ivory Cross National Dental Aid Fund of the Royal Northern Hospital." The Dental Aid Fund was quite distinct from the Royal Northern Hospital and nobody connected with the hospital figured on the invitation card.

Mr. Justice Finlay said: "There can be no doubt that the president and officers of the eminent charity concerned knew nothing about it."

I am, Sir, yours faithfully,

GILBERT G. PANTER,

Secretary, Royal Northern Hospital.

Holloway, N.7, Feb. 11th.

ACETYLCHOLINE FOR PAROXYSMAL TACHYCARDIA

To the Editor of THE LANCET

SIR,—In an article in your issue of Dec. 7th, 1935 (p. 1291), I quoted Dr. Isaac Starr Jr., of the University of Pennsylvania, Philadelphia, as having used acetylcholine in a series of cases of paroxysmal tachycardia. I have since received an interesting letter from Dr. Starr, in which he says, amongst other things:—

"I write to try to clear up a point which I am afraid may cause serious difficulty if it is not appreciated. You speak of me as having described the termination of paroxysmal tachycardia after subcutaneous injections of acetylcholine. This is not correct. I used acetyl- β -methylcholine, trade name, Mecholyl, made by E. Merck (Darmstadt). Given subcutaneously this is somewhere between ten and twenty times as powerful as acetylcholine. Like yourself, I have never seen any unpleasant sequelæ after injecting acetylcholine in the dosage you gave. Indeed doses of this size are seldom followed by demonstrable drug effect. On the other hand an injection of 75 mg. of acetyl- β -methylcholine to a boy of 14 would probably have produced enough vagus effect to stop the heart altogether and I would make no guarantee that it

would resume. I hope you will do what you can to get the different pharmacological effects of the many active choline derivatives straightened out in the minds of the physicians. I am very fearful that someone may use acetyl- β -methylcholine in the dosage proper for acetylcholine subcutaneously. If so, I hope they have atropine ready at hand."

I hope the publication of this letter will be an appropriate warning; and I should like to take this opportunity of apologising to Dr. Starr for having misquoted his work.—I am, Sir, yours faithfully,

A. B. STENHOUSE.

Radcliffe Infirmary, Oxford, Feb. 10th.

CHILD BORN WITH A FOREIGN BODY IN THE HEART

To the Editor of THE LANCET

SIR,—We are fully aware of the incredible nature of this case, but feel impelled to place on record what we believe to be an occurrence unique in the annals of pathology.

A female child was born at term to a primipara who had an uneventful gestation and a normal labour. The baby also appeared normal in every way, but died suddenly some hours after birth, and for no apparent reason. A post-mortem was ordered, and this was carried out with meticulous care by one of us (T. T. W. E.) in the presence of the other (W. M. C.), who was assisting and observing closely, as the case was his, there being no professional connexion between us. The mortuary attendant was also a witness.

Nothing of importance was observed until the heart was removed, laid beside the body on the post-mortem slab, and dissected with a scalpel and a pair of surgical scissors, which were unplated. On opening the right ventricle, a small, bright object was seen lying free within the cavity, and was extracted under three pairs of curious eyes. It was a small piece of metal resembling brass or gilded tin, appearing to be a circlet of sorts, folded upon itself, with regular serrations along its edge, and measuring roughly 3 by 2 mm. It looked something like the claw setting of a toy jewel ring such as is found in Christmas crackers.

We emphasise that there was no possibility of its having been dropped by one of us as we bent over the heart; of its having been shed by one of the instruments used; or of its having been picked up from the post-mortem table. We very naturally examined these possibilities critically before ruling them out. The explanation of its presence, forced upon us by exclusion, seems as fantastic as the discovery itself; but we would welcome alternative suggestions. It is, that the foreign body was lying within the mother's uterus at the time of conception and that the growing ovum enfolded it, so that it finally came to lie where it was found. When the placental circulation ceased and the child's heart "took over," it caused some momentary effect which produced syncope.—We are, Sir, yours faithfully,

T. T. W. EATON,

W. MULHALL CORBET.

Canvey Island, Feb. 8th.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Rear-Admiral John S. Dudding, C.B., O.B.E., K.H.P., has been placed on the Retd. List at his own request on relinquishing charge of the R.N. Hospital, Plymouth, where he has served for three years. Surg. Rear-Admiral Francis J. Gowans, who in 1933-35 was in medical charge of the hospital ship *Maine* has succeeded him.

Surg. Comdr. W. G. C. Fitzpatrick to *Vernon*.
Surg. Lt.-Comdr. V. G. Horan, M.B., to *Pembroke* for R.N. Hospital, Chatham.
Surg. Lt.-Comdr. (D.) S. Mawer to *Drake* for R.N.B.
Surg. Lt. (D.) W. J. Wolton to *Hood*.
Surg. Lt. E. J. Littledale to *St. Vincent*.

ROYAL NAVAL VOLUNTEER RESERVE

Proby. Surg. Sub-Lts. to be Surg. Sub-Lts.: R. T. May, P. de B. Turtle, R. F. B. Bennett, C. P. Nicholas, and L. S. Anderson.

ARMY MEDICAL SERVICES

Lt.-Col. S. W. Kyle, from R.A.M.C., to be temp. Col. while employed as A.D.M.S., 5th Div.
Lt.-Col. R. M. King, from A.D. Corps, to be Col.

ROYAL ARMY MEDICAL CORPS

Capt. G. Anderton, R. J. G. Hyde, and R. V. Franklin to be Maj.

Capt. N. H. Lindsay, h.p. list, is restd. to the estab. The results are announced of the examination (in written subjects) of officers with a view to promotion in the Regular Army, Indian Army, and Dominion Forces, which was held at stations abroad (excluding India) last October. Among the successful candidates were Capt. T. F. M. Woods and M. R. Burke, R.A.M.C., and Maj. J. E. A. Tessier, Royal Canadian Army Medical Corps.

ARMY DENTAL CORPS.

Maj. J. S. Smith to be Lt.-Col.

TERRITORIAL ARMY

Col. P. H. Mitchiner, T.D., K.H.S., from A.D.M.S., 47th (2nd Lond.) Div., is attd. to the 1st Anti-Aircraft Div. for duty as A.D.M.S.

Lt.-Col. W. A. Robertson, M.C., from R.A.M.C., to be Col. and is apptd. A.D.M.S., 51st (Highland) Div.

Lt.-Col. and Bt.-Col. W. A. Robertson, M.C., from T. A. Res. of Off., to be Lt.-Col. and relinquishes the Brevet rank of Col.

Lts. H. C. Stewart and P. Brookes to be Capt.
Col. R. E. Bickerton, D.S.O., T.D., from 56th (1st Lond.) Div., to be Hon. Col., R.A.M.C. Units, The Lond. Div.
The surname of Lt. J. L. Cowan, M.D., M.R.C.P. Edin., is as now described and not as notified in the *Gazette* of Jan. 24th, 1936.

J. R. Dawson to be Lt.

ROYAL AIR FORCE

Wing-Comdr. J. Kyle to Medical Training Depôt, Halton, for duty as Commanding Officer, vice Group Capt. E. W. Craig, M.C.

Flight Lts. J. Hutchieson and C. A. Lewis to R.A.F. General Hospital, Hinaidi, Iraq.

Flight Lt. J. Hill is promoted to the rank of Squadron Leader.

Flying Offrs. H. L. Willcox, R. A. Cumming, and L. E. A. Dearberg to R.A.F. General Hospital, Hinaidi, Iraq; S. R. C. Nelson to Central Medical Establishment, London.

Flying Offr. W. G. S. Roberts is promoted to the rank of Flight Lt.

DEATHS IN THE SERVICES

The death occurred in London on Feb. 4th of Major ARTHUR EDWARD MILNER, R.A.M.C. Born in 1867 he was educated at Bristol and Guy's Hospital, where he was Clark scholar in surgery and Saunders scholar in medicine. After taking the conjoint qualification in 1892 he won the Montefiore prize in military surgery at Netley, and entered the Army as a surgeon lieutenant. He became captain in 1897, major in 1906, seeing service on the N.W. frontier of India and with the Tirah Expeditionary Force, when he was awarded a medal with 2 clasps. In the South African War he took part in operations in Natal and at the defence of Ladysmith, gaining the Queen's medal with 3 clasps. He was placed on retired pay in July, 1914, but a month later was recalled to the active list.

PUBLIC HEALTH

MENINGEAL TUBERCULOSIS

EPIDEMIOLOGY AND TYPE OF TUBERCLE BACILLI

By W. T. MUNRO, M.D. St. And., F.R.C.P. Edin.

MEDICAL SUPERINTENDENT, GLENLOMOND SANATORIUM,
KINROSS; AND

HAROLD SCOTT, M.B. St. And.

ASSISTANT MEDICAL OFFICER AT THE SANATORIUM

In 1932 Dr. Stanley Griffith¹ reviewed the relative incidence of human and bovine tubercle bacilli in meningeal tuberculosis in England. Most of these viruses were obtained from Leeds and the surprising feature was that 10 out of 30 specimens of cerebro-spinal fluid yielded bovine type bacilli. In a later communication² he dealt with 214 English and 37 Scottish cases. The former yielded 52 (24·3 per cent.) bovine types, while the latter yielded 15 (40·5 per cent.). The English cases were from widely different localities. From Leeds one noted 10 bovine infections among 49 city cases (20 per cent.) and 8 bovine infections among 17 rural cases (47 per cent.). Throughout this report there was a higher incidence of bovine types in rural areas.

The Scottish cases reported by Dr. Griffith in this review included 18 of the present series with 33 per cent. bovine types; 15 from Aberdeen with 47 per cent. bovine types; and 4 from Ayr with 50 per cent. bovine types.

Dr. Agnes Macgregor has since reported³ that 14 out of 50 cases of meningeal tuberculosis in Edinburgh (28 per cent.) could be ascribed to bovine bacilli; only 8 of these 50 lived in rural areas and 3 of these were infected with the bovine type. Dr. Blacklock⁴ states that 12 out of 60 cases in Glasgow (20 per cent.) yielded bovine bacilli, and notes that the bovine percentage was higher in country (27) than in city (18) children.

The series here described comprises cases of meningeal tuberculosis from Glenlomonid Sanatorium admitted from year 1924 to date, and specimens of cerebro-spinal fluid sent us between 1932 and 1935 from the wards of the Royal Infirmary, Dundee, by Prof. A. Patrick, Dr. James Thomson, and Dr. Gordon Clark, to whom we are much indebted for information. Specimens of cerebro-spinal fluid from 59 cases have been examined. Meningeal tuberculosis is not an uncommon mode of death in cases of chronic pulmonary tuberculosis and 9 of the specimens examined were from such patients. These were all adults whose sputa yielded us eugonic growths of typical human types and similar types were also grown from the cerebro-spinal fluids. These 9 cases are not included so that we limit our review to cerebro-spinal fluids from 50 patients who came under observation on account of symptoms suggesting meningeal involvement.

In our earlier cases no attempt was made to obtain growths direct from the cerebro-spinal fluid and the fluid was injected into a guinea-pig. In later years, as we became more certain of growth, direct inoculation of suitable media became the rule and was carried out as well as inoculation of a guinea-pig. In all, 27 were obtained by direct inoculation, while the others were obtained solely by inoculation of a guinea-pig.

DISTRIBUTION OF CASES

Of the 50 cases 14 were from Glenlomonid and 36 from the Royal Infirmary, Dundee. Of the

Glenlomonid cases 7 and of the Dundee cases 11 proved bovine in type. Glenlomonid Sanatorium receives its patients from the counties of Fife and Kinross, but exclusive of the large burghs of Kirkcaldy and Dunfermline; so that apart from some smaller burghs the patients are drawn from purely rural areas.

Of the Dundee patients 4 (in each of whom the virus was found to be bovine) came from rural areas—viz., 3 from rural Perthshire and 1 from a rural district of the county of Angus. No human type Dundee case came from a rural area, so that, all told, 18 cases came from rural areas and yielded 11 bovine types, while 32 cases were urban and yielded 7 bovine types.

Tuberculosis in the human subject due to bovine bacilli is much more a rural than an urban problem and this aspect will be more in evidence as facts are elicited in this paper.

CULTURAL CHARACTERISTICS AND PATHOGENICITY

Of 50 strains, 18 (36 per cent.) exhibited the cultural characteristics of the bovine type bacillus while 32 were identical with the eugonic human type bacillus.

Before acceptance of a dysgonic moist-looking growth as being a bovine type a pathogenicity test has always been carried out, and the test used by us is the intravenous inoculation of a rabbit of about 1500 g. weight with 0·01 mg. of the wet virus. A bovine strain will kill the rabbit in approximately thirty days, the lesions being those of progressive generalised tuberculosis, while the human strain in the same dose will scarcely ever kill the rabbit and certainly not in less than 90 days, and as a rule produces only minimal non-progressive lesions. All the dysgonic types proved fully virulent to the rabbit and were true bovine types. Moreover, all these viruses were examined at Cambridge by Dr. A. Stanley Griffith and accepted as bovine types.

Table I. shows the age-distribution according to type.

TABLE I

—	Total.	Human.	Bovine and per cent.
0-5 years	20	9	11 (55)
5-15 „	18	14	4 (22·2)
Over 15 „	12	9	3 (25)
—	50	32	18 (36)

These figures do not surprise us in any way. We were quite prepared for a high percentage of bovine types in the age-group 0-5 years. All the children under two years of age who showed disease due to the bovine type bacillus had been fed on cow's milk unboiled.

Noteworthy too is the number of bovine types found in persons over 15 years. The oldest in the series was the case of a ploughman of 30 years of age.

RURAL AND URBAN DISTRIBUTION

When we come to separate our cases by a rural and urban distribution, we meet with some very significant facts as shown in Table II.

It will be seen that there is a big difference in the percentage of bovine infections in rural and urban areas. This is to be expected, for there is no pasteurisation of milk in rural areas and no dilution of infection by bulking. In Dundee about 60-70 per cent. of the city's supply may be considered safe,

whereas it is doubtful if any rural supply can be considered safe apart from milk from a tubercle-free herd. The significant fact is that the incidence of

TABLE II

Total	25	7	7	11
Percentage bovine ..	—	21·9	—	60·1

bovine types is three times greater in the rural areas than in the city. The only protection in rural areas is to boil the milk.

EPIDEMIOLOGY

The Tables show that the rural population supplies us with far the greater proportion of our cases due to the bovine bacillus. Even in the later age-periods we find cases of meningeal tuberculosis due to the bovine type from rural areas. Dr. Griffith reports the case of a man of 32 years of age from Lincolnshire whose cerebro-spinal fluid yielded a bovine virus and the oldest case in our series is that of a ploughman, 30 years of age, from Perthshire; while we can also show the cases of a youth of 19 from Fifeshire and a girl of 17 from Perthshire, from each of whom bovine types were obtained. Ploughmen in Scotland usually receive milk from the farm as part payment, and the question of compensation might reasonably arise if disease due to the bovine bacillus was found to be the cause of death. The difficulty would be to fix the actual source of the infection. Ploughmen do not remain long in one service.

In the prevention of tuberculosis, one of us has previously stressed the fact that after notification of a case of meningeal tuberculosis the family must be carefully reviewed, especially to ascertain if there is a case of pulmonary tuberculosis or other visceral tuberculosis in the household. If no other case of tuberculous disease is found, full inquiry as to the source of the milk-supply must be made.

With regard to the cases from Fife county, it was easy for us to get all the facts. In every instance where a human type virus was found in the cerebro-spinal fluid there was, or had been, a known case of pulmonary tuberculosis in the home. With regard to the bovine types from Fife county, the discovery of so many cases of pulmonary tuberculosis due to the bovine type virus makes us keep in mind that we must be careful to review the whole family even if we do know the virus from the cerebro-spinal fluid is bovine in type. In no case due to the bovine type from Fife, however, did we find anyone with visceral tuberculosis in the home, and so in these cases we were forced to regard the milk-supply as the likely source of infection.

In recent years it has been our practice to notify Dr. G. Pratt Yule, medical officer of health of Fife, at once whenever we have found bovine type in a cerebro-spinal fluid. From the cases notified, Dr. Yule has been able to find an offending cow in two instances. We were much disappointed to be unable to find the source in the case of an eight months' old child whose virus was bovine in type. Careful examination of the herd by the county veterinary officer failed to reveal disease in any cow and a biological test of the milk proved negative.

Urban cases.—When we come to consider the epidemiology of the cases from Dundee, we confine our inquiries to those cases in which a bovine virus was obtained. We are indebted to Dr. John Hunter, tuberculosis officer, Dundee, for his help in obtaining full information about these cases.

In Dundee there are two large companies which pasteurise milk and over 50 per cent. of the city's supply is pasteurised, while 10 per cent. will be from tubercle-free herds; so that probably between 60 and 70 per cent. of the supply will be safe. There are many deliveries from the churn by cart and there are a few dairies in the city where cows are bought in and milked till dry and then sold. These cows never go out from the byre.

In 11 instances the bovine type virus was found. The family history in one case revealed that the father suffered from pulmonary tuberculosis and tubercle bacilli of human type were obtained from his sputum; he had also had extensive tuberculosis of the cervical lymph nodes ten years previously. This finding is in keeping with those cases described by Walker⁵ when he reviewed the lack of evidence of human-to-human infection by the bovine type. In this case there was opportunity of infection by milk as the supply was not from a safe source.

In one other case there was a history that the father had had a hæmoptysis, but no sputum ever was obtained.

In every case the milk-supply was from a doubtful source and there was a common dairy in three instances. This information has been passed to the medical officer of health and we learn that this dairy buys in milk for sale. It will be most difficult to overtake a complete examination of the cows in such a circumstance.

IS THE PRESENT LEGISLATION SUFFICIENT FOR THE EXAMINATION OF COWS?

The 1914 Milk and Dairies Act is the Order under which a local authority can act. This is supplemented by the Tuberculosis Order, 1925. These appear to us to be utterly insufficient and the faults lie in two places.

Firstly, the definition of a dairy is too restricted. The term includes any creamery, farm, &c., from which milk is sold or supplied for sale, but excludes premises where cows are kept solely for the use of the farmer and his servants, or where milk is sold to a very limited number of neighbours. Therefore such premises need not be registered and there is no inspection.

With the knowledge that deaths have occurred among farm servants, and that cervical lymph-node tuberculosis is not uncommon among farm servants' families, being often due to the bovine type bacillus, it is obvious that all places where milk is obtained should be inspected. This is not meant to imply that the farmer is careless as to milk-supply to his staff. For example:—

A farmer residing a few miles from Glenlomon Sanatorium purchased a cow as sound, the milk to go to his staff. The farm grieve and his wife did the milking and noted at once a slight induration in one quarter. The cow was again examined and passed as sound, but the grieve brought the strippings of the indurated quarter here for examination and numerous tubercle bacilli were found. On report of this the farmer had the animal destroyed at once and examination revealed extensive tuberculous disease.

The farmer who merely keeps cows to supply milk to his staff would, we feel sure, not knowingly retain an unsound cow, but there ought to be inspection.

The second serious defect in the Order lies in the qualification of disease in the cow. The cow-keeper must report to the local authority if a cow (1) has a chronic cough, (2) is emaciated, or (3) has disease or induration in an udder. But these, surely, are terminal features? A cow in any such state, if tuberculosis is the cause, will have done all the damage she can do, and we can hardly think that the dairy farmer only suspects when any of the above-mentioned states is present. And the amazing feature in the Order follows. If the dairy farmer reports such an animal to the local authority and on inspection tuberculosis is found he is compensated. It is very different with other tradesmen. A sale of adulterated foodstuffs is punishable but the farmer is compensated if he notifies an unsound beast.

These Orders do not deal with the problem at all, but leave it possible to profit by the sale of unsound milk and subsequently by notification of the unsound cow.

CONCLUSIONS

Of 50 cases of meningeal tuberculosis 18 (36 per cent.) were attributable to bacilli of bovine type. Rural cases give 60 per cent. of bovine types while urban cases yield 22 per cent. Taking the figures for Fife alone, we find that 7 out of 14 (50 per cent.) are of bovine type—a figure which probably gives a better idea of the actual position. Tuberculosis due to the bovine type is an urgent rural problem, and the present legislation is inadequate.

Medical Inspection in American Schools

It is a common experience to meet a friend just returned from a foreign country full of enthusiasm for its wonderful organisation, and soon after another who has nothing to tell but of its backwardness and deplorable conditions. Strangely contradictory accounts have been given of the state of school medical work in America and the discrepancies may be resolved by study of a searching review by Dr. J. F. Rogers, of Washington, in the *Quarterly Bulletin* of the League of Nations Health Organisation. The degree of efficiency ranges from organisation such as that in New York State to that in Illinois. In New York State there is a director with a central staff of eight : (1) a general supervisor of medical inspection ; a supervisor of (2) sight and hearing ; (3) oral hygiene ; (4) heart and lungs ; (5) psychiatry ; (6), (7) two supervisors of school nursing ; and (8) a supervisor of health for teacher-education institutions. The outside staff consists of 1300 school medical inspectors and 600 nurses. The inspectors have had special post-graduate training in the principles of health education and in its organisation in public schools. The nurses, after full training, have all taken an approved course in health education. There are besides many trained dental hygienists working under the dentists. In Illinois there is no legislation on the subject at all, and this is the case in 5 other States ; although in some of these there may be good systems of examination in certain schools. In 27 the law is mandatory, in 13 it is merely permissive. The inspections are carried out in 3 States by the county health officer, in 5 by a physician, in 9 by a physician or a nurse, in 6 by a physician or a teacher, in 5 by a physician, teacher, or nurse, in 3 by a nurse, in

7 by a teacher, and in 2 by a dentist only. Obviously a teacher cannot make a full medical examination but he may recognise defects such as those of sight and hearing, and in some places teachers are given specific instruction in the detection of gross defects.

On the credit side of the account must be put the fact that in 20 States the examinations are annual—a frequency which is being advocated by some reformers in this country. Against this must be set the fact that in only 14 States is there a full general medical examination. In general the object of the inspection is to remove obstacles to education rather than to promote better health and physique. The school medical officer who has graduated in public health is nearly non-existent. The administration is more often conducted by the education department than by the health authority, and this bias is increasing ; there is something to be said for it if it is true that there is less of politics in the work of education than of public health and hence a more secure tenure of office and personnel. The examinations are looked upon as educational in another sense ; they teach the children, and perhaps their parents, the value of periodic medical supervision and may lead to the habit of seeking it in later life. Instruction in hygiene does not appear to be widely organised.

Special schools for the blind and partially blind, for the deaf and hard of hearing, for the crippled and the delicate, are highly developed in some States and non-existent in others. Some types of special schools—e.g., those for the partially deaf—can, we believe, be definitely traced to the example of our own country. Treatment facilities vary greatly. A common practice is just to inform a parent that the child "seems to be suffering" from some abnormal condition. Apart from dental clinics there are few treatment centres, and even within the boundaries of New York State the proportion of defects treated varies from 15 to 95 per cent.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 1ST, 1936

Notifications.—The following cases of infectious disease were notified during the week : Small-pox, 0 ; scarlet fever, 2509 ; diphtheria, 1304 ; enteric fever, 27 ; acute pneumonia (primary or influenzal), 1605 ; puerperal fever, 52 ; puerperal pyrexia, 101 ; cerebro-spinal fever, 27 ; acute poliomyelitis, 6 ; encephalitis lethargica, 3 ; dysentery, 52 ; ophthalmia neonatorum, 65. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Feb. 7th was 4233, which included : Scarlet fever, 1089 ; diphtheria, 1096 ; measles, 693 ; whooping-cough, 681 ; puerperal fever, 17 mothers (plus 13 babies) ; encephalitis lethargica, 281 ; poliomyelitis, 4. At St. Margaret's Hospital there were 24 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 41 (5) from measles, 4 (0) from scarlet fever, 25 (2) from whooping-cough, 46 (8) from diphtheria, 58 (21) from diarrhoea and enteritis under two years, and 98 (19) from influenza. The figures in parentheses are those for London itself.

The mortality from influenza is maintained, the total deaths for the last nine weeks (working backwards) being 98, 104, 89, 110, 110, 80, 67, 62, 45. The deaths this week are scattered over 46 great towns, Birmingham reporting 9, Manchester 5, Bradford 4, Leeds 3, no other great town more than 2. Liverpool had to report 11 deaths from measles, Salford 5, Sheffield and Warrington each 3. Liverpool also reported 5 deaths from whooping-cough, Birmingham 3. Deaths from diphtheria were reported from 29 great towns : 3 each from Hull, Liverpool, and Plymouth, 2 each from Bradford, Manchester, and Birmingham.

The number of stillbirths notified during the week was 251 (corresponding to a rate of 42 per 1000 total births), including 31 in London.

OBITUARY

SIR CHARLES BALLANCE

THE death occurred on Saturday last of the distinguished surgeon and neurologist, Sir Charles Ballance; he was 79 years of age and had been recently in a delicate state of health. A notice of his life will appear later. The following tribute to him as man and worker has been received from Sir Charles Sherrington: "As one who knew Sir Charles Ballance and in earlier years saw him much I gladly accept the suggestion to pay his memory, at this time of our loss, some tribute in words even if brief. Between the years 1887 and 1895 at St. Thomas's Hospital medical school, Ballance, and with him Walter Edmunds, was a colleague who, I might say literally, frequented the physiological laboratory. Among other research which the two did there were their experiments on the bursting strain of arteries. Also at the Brown Institution, which was under me in those days, they did work on the thyroid and the results of its extirpation in the monkey.

"For Ballance in those years any hour up to 10 o'clock in the evening might bring him. He used to smile and say, 'at home they have yet to understand that I like my coffee cold!' The microscope would occupy us sometimes until after midnight. He was interested in an experimental study as to the source and behaviour of the cells which repair after inflammation. He would be so keen in following the movement of the cells that he would read 'motives' into their behaviour. In Walter Edmunds he had an admirably objective collaborator. Their tracing of how the tied artery becomes structurally closed when and where ligated in continuity without rupture of its coats stands as a monument to their admirable collaboration.

"A colleague with whom in those years, and after, he did much research was Samuel Shattock. At the period I am alluding to they were engaged in a quest for possible parasitic protozoa in cancer. They conducted the search with attempts at culture as well as by microscopic examination of the cancerous tissue. I was privileged to look on at times, and the pains taken, the long patience shown, the scrupulous loyalty to results dishearteningly negative were an example to remember. Ballance had an enthusiastic admiration for Shattock's great knowledge of and experience in morbid macro- and micro-anatomy. He would compare, and prefer, him to Rudolf Virchow, and add, 'Shattock will never disappear into politics!' a remark with which it was not difficult for all who knew Shattock, and that he carried habitually with him a copy of St. Francis of Assisi, to concur.

"After removing from London I had to my regret far less opportunity of seeing Ballance. When I did he always renewed just the same frank friendship. His enthusiasm for laboratory research in surgery did not diminish. He had undertaken his experiments on nerve-suture and nerve-grafting and the repair of nerves. The experimental work by David Ferrier always remained a source of inspiration to Ballance. He appraised Ferrier's work on the removal of portions of the brain in apes as the actual pioneer-step leading to modern cerebral surgery. He followed with intense interest the recent developments by his own college, the Royal College of Surgeons of England, in providing facilities for experimental research in surgery—namely, the field laboratory at Down, in Kent, and the installation of experimental laboratories in the College itself.

"If as he grew older he seemed a little liable to 'preach' somewhat, this is explained by the fact that the theme of which he never tired was experimental research in surgery. Ballance was sincerity itself. A scrupulously conscientious man, on the invasion of Belgium by Germany in 1914 he took the German decoration, bestowed on him some years before, to the Thames Embankment and flung it into the river, an incident he would relate with a short laugh of satisfaction. In 1933 he was awarded the Lister Memorial medal and gave the Lister Memorial lecture. This latter gave him opportunity to report upon and to demonstrate some of his latest work, done with junior colleagues, on nerve-grafting. The award and the occasion were a profound satisfaction to him. Those who were present are not likely to forget the impression he conveyed to all there of what he stood for."

WILLIAM HENRY BATTLE, F.R.C.S. Eng.

CONSULTING SURGEON, ST. THOMAS'S HOSPITAL

THE death occurred early on Sunday morning, Feb. 2nd, of William Henry Battle, consulting surgeon to St. Thomas's Hospital, following an illness of several months' duration.

Born in Lincoln in 1855, the son of Mr. F. R. Battle, an alderman of that city, he was one of a family of nineteen children. He received his general education at Lincoln Grammar School and entered St. Thomas's Hospital in 1873. He was a successful student, a prizeman and Solly medallist, and obtained the diplomas of M.R.C.S. Eng. and L.S.A. Lond. in 1877. He served

a fine apprenticeship to his later position on the staff of St. Thomas's, being house physician, house surgeon, and resident accoucheur. In 1880 he took the diploma of F.R.C.S. and became surgical registrar at the hospital, proceeding to the position of resident assistant surgeon. At the same time he began a long connexion with the Royal Free Hospital by appointment to the staff as assistant surgeon

and demonstrator of practical surgery in the School of Medicine for Women. He continued his early obstetric work by acting as surgeon to the Dispensary for Women in Shadwell and was also appointed to the staff of the East London Hospital for Children.

In 1892 Battle became assistant surgeon to St. Thomas's Hospital, and in that year, in succession to Sir John Tweedy, he joined the staff of THE LANCET as general surgical adviser. Such was the arrangement of work within the office of THE LANCET in those days that this post implied the editing of a department entitled A Mirror of Hospital Practice, a section of the paper that was much developed by Tweedy. It entailed the personal visiting of the

MR. BATTLE

(Photograph by Beresford)

operating theatres in London on certain days, as well as the securing of reports from the theatres of large hospitals without the metropolis. Already when Battle succeeded to the work its design, framed in an era when operations were few and when it was possible to relegate their performance to particular hours of the week, had become ill-defined, for the task of anything like inclusive reporting could not be attempted. Thus under Battle's editorship the *Mirror of Hospital Practice* changed in character and became a method of personal approach by the paper to authors whose contributions would be obviously valuable to our readers. In this way Battle served the paper well, while it was his habit, following that of Tweedy, to precede the accounts of the operations reported with historical notes of analogous cases or of similar displays of technique, such as to-day are very usually furnished by the authors themselves in relation to their communications. The provision of these notes, which sometimes formed a ground-plan for longer articles, came the easier to Battle, in that he had been editor for two years of the surgical reports of St. Thomas's Hospital and a frequent contributor to those reports. He seldom recorded in the *Mirror of Hospital Practice* any work of his own, but he published in our columns, in the *Transactions of the Pathological Society* and in those of the *Clinical Society*, numerous articles dealing with a large range of clinical subjects.

In 1890 Battle was appointed a Hunterian professor at the College of Surgeons, and delivered a valuable series of lectures on injuries to the head. The composition of these lectures entailed upon him investigation of a large number of recorded cases, and the work, carried out with judgment and acumen, brought together in readable form a great deal of valuable information. In 1906, now full surgeon to St. Thomas's Hospital and the Royal Free as well as joint lecturer in practical surgery at the former institution, he gave a course of clinical lectures at St. Thomas's, entitled the "acute abdomen," in which he pointed out in a detailed manner the difficulties presented in diagnosis, and therefore in the first stages of treatment, presented by cases of appendicitis, intestinal obstruction, intussusception, perforations in the alimentary tract, and gynaecological inflammation. His personal knowledge ranged almost from the time when operative interference in these spheres was contemplated only as a last resource, so that he was able to tell the full story in a graphic manner.

In addition to these lectures and reports he wrote, in collaboration with Mr. E. M. Corner, a practical treatise on the appendix and its surgical complications. The work attained to a second edition and marked the great interest with which Battle had always followed the development of abdominal surgery. Its publication added to his high claims to prominence as a surgeon. "In my opinion," writes Mr. Corner, "he was unequalled for dexterity and clever manipulation in abdominal conditions. His ingenuity and boldness were justified by good results. He could on necessity be extremely quick and when the unexpected happened he was never disturbed, for his skill and experience allowed him to adapt procedure in accordance with emergencies. As a teacher he was forcible, distinct, and quiet, and the practical value of his advice was aided by care in suiting his instruction to his audiences. As a colleague I can speak of him as always reasonable, consistent, and loyal. He earned the respect of all who worked with him."

Battle at the time of his death was consulting surgeon at the Royal Free Hospital, and Mr. Willmott Evans, who for many years was his colleague at that institution, describes the many opportunities he had of seeing Battle at work. He writes as follows: "As a surgeon Battle was an expert operator, rapid where the facts showed the need for action, but in all doubtful cases very careful. He was a scrupulous diagnostician so that the information obtained at the operation usually coincided exactly with his first opinion, although he never had any hesitation in modifying his diagnosis as further information or circumstances warranted. His teaching at the medical school associated with the Royal Free Hospital was much valued, especially by the senior students who could appreciate the caution with which he balanced his data, although he showed his care in the instruction of more junior students by his readiness to clear up any point in his lectures or demonstrations which presented difficulty to them. He always took particular pains to point out to students which were the things that seemed to him of the most importance when coming to conclusions, so that he effectively made clear the basis on which his teaching was formed and the circumstances which should dictate diagnosis."

Battle's interest in the diagnosis to be made and the procedure to be followed in abdominal surgery continued through his life. As far back as 1910 he delivered the annual oration to the Medical Society of London upon intraperitoneal injuries, and in that discourse gave a lucid description of where particular attention should be paid in ascertaining the exact lesion present. And only three years ago, after considerable retirement from St. Thomas's Hospital, he wrote in these columns a valuable letter upon the occurrence of appendicitis, considering that obvious evidence existed for a thorough scrutiny into the increasing incidence of the disease.

Mr. Battle retired from the position of surgeon at St. Thomas's Hospital in 1925 with the rank of consultant, leaving behind him the reputation of a devoted hospital servant as well as a great surgeon and teacher.

Sir Cuthbert Wallace writes: "Every surgeon has attributes by which he is remembered by those that he taught. In thinking of Battle the one thing that stands out in my memory was his devotion to his duty as shown by his regularity of attendance on his hospital days. Nothing interfered with his hospital work and a student was sure to find him in his ward at the appointed time, and was equally sure of having a profitable afternoon. His teaching was simple, clear, direct, and seemed to supply just what the student wanted. This resulted in his having a large following in the wards whenever he appeared. He had a wide knowledge of the literature of his subjects and no doubt his constant writing for the journals crystallised useful data in his mind and enabled him to distinguish facts from theories, much to the advantage of those he taught. As a surgeon he may be described as sure and safe rather than brilliant, and as an operator he was neat, quiet, and without fuss. Many men still practising must have grateful thoughts for Battle."

Mr. Battle married in 1892 Anna Marguerite Vulliamy by whom he had three sons and two daughters. One son was killed in the war, and of

the survivors one is squadron-leader in the R.A.F. and the other is Mr. Richard Battle, who follows in his father's footsteps as surgical registrar at St. Thomas's Hospital.

FARQUHAR MACRAE, M.B. Glasg.

WE regret to announce the death of Mr. Farquhar Macrae which occurred on Feb. 2nd at Newmill, St. Andrews, where he had retired in 1929 after a long period of surgical practice in Glasgow and the West of Scotland.

Farquhar Macrae graduated M.B., C.M., with commendation at Glasgow University in 1895, after which he acted as house surgeon and house physician at the Glasgow Western Infirmary and Royal Hospital for Sick Children. At the termination of these appointments he studied under Prof. W. D. Halliburton at King's College, London, for some time, and thereafter became

MR. MACRAE

[Photograph by Annan

assistant to Sir Arthur Mayo Robson in Leeds. It was during this time that he gained that insight into gall-bladder surgery which stood him in great stead in later life. After a few years in Leeds, he returned to Glasgow and was appointed surgeon to the out-patient department at the Western Infirmary, where he was associated with Sir Hector Cameron and Sir Kennedy Dalziel, both in hospital and

private practice. Later he was appointed to the post of assistant surgeon to the Victoria Infirmary, surgeon to the City of Glasgow Fever Hospitals, and consultant surgeon to Ayr County Hospital. He returned to the Western Infirmary in 1922 as visiting surgeon and was appointed a lecturer in surgery to the university. On various occasions he acted as examiner in surgery both at Glasgow and Edinburgh Universities, and was a fellow of the Association of Surgeons of Great Britain and Ireland.

On his retirement in 1929 he bought a house at St. Andrews, but shortly afterwards he was invited by the General Medical Council to undertake the duties of inspector of examinations. These occupied the best part of three years, and at their termination he forwarded to the G.M.C. a report which was at once recognised as being of the greatest importance. His excellent work here led in 1933 to his being asked by the India Office to undertake the post of secretary-inspector to the newly formed Indian Medical Council and he proceeded to India, remaining there for more than a year. He found the work one of great delicacy for an official not possessing special knowledge of India and Indian educational standards, but he did valuable work in preparing the ground.

Macrae never wrote much, but he was ever a keen student of the literature of his subject and was possessed of the rare faculty of being able to sift the

grain from the chaff. Among his publications are the following: Editor, "Diseases of the Gall-bladder and Bile-ducts," second edition, 1900; joint author, Affections of the Gall-bladder and Bile-ducts, Encyc. Med.; Diagnosis of Peritonitis occurring during Enteric Fever; Cholelithiasis, Diagnosis, and Treatment, *Brit. Med. Jour.*, 1922; Diagnosis in Abdominal Diseases, Finlayson's "Manual of Clinical Medicine," 1927.

He was a man much loved by all who knew him well. With tall stature and strong countenance, he inspired great confidence in his patients and friends, while his wide experience and sound knowledge were always available to those who sought his help. As a clinician he was outstanding, so that he attracted large numbers of students to his clinics. His teaching was inspiring, based on a wide knowledge of pathology and literature in general. He was sometimes of short temper and could then employ a cutting tongue, but his actions were never petty, and he was a particularly sound judge of men, and was often consulted regarding appointments.

Farquhar Macrae built up a large surgical practice and when he retired in 1929 his loss both as surgeon and man was felt to be great. He leaves a widow to whom we extend our deepest sympathy.

A colleague of Farquhar Macrae writes: "The death of Mr. Farquhar Macrae is a great loss to the medical profession and to his many friends. His career has been outlined above and his surgical influence on the Glasgow school appreciated, but it is the influence and personality of the man which I would emphasise. Macrae had not many degrees, nor did he publish frequently. He did not seek publicity, and believed in inherent ability and honesty of purpose. Outstandingly he was a man. A tall, handsome figure, somewhat severe in expression, he inspired great confidence in all who met him; and more than confidence, for sympathy where deserved was one of his great attributes. Children loved him, and with them he was at his best. His simplicity of heart, ready understanding, and directness of purpose without excuse or explanation endeared him to them, and children are seldom wrong. The personality, the poise, the honesty of Macrae are seldom found in one human being, and with those he combined wealth of clinical acumen—that clinical sense which is of more value than much book learning; yet he had an intimate knowledge of all recent advances and a keen critical faculty as to their value.

"After his retiral in 1929 he acted as inspector of examinations for the G.M.C. and for the Dental Council. His reports on these matters were so excellent that he was appointed to an extremely responsible post as secretary to the Medical Council for India. The strain and difficulties of this and the climate of India had their effect on his health and he was unable to continue and returned to St. Andrews after fourteen months' service to carry on his interest in the furtherance of medical problems and study, his work in India having laid a sound foundation for a successor. Unfortunately his illness proved more serious than was supposed and he had not many months left of active life. His funeral was attended by many friends, and his great relaxation of golf was made noticeable by the fact that a number of St. Andrews' caddies attended the graveside. They, like his medical and lay friends, appreciated the greatness of the man, great of stature, great of mind; they understood his personality, his humour,

and his loveliness. We who knew him mourn him deeply and doubt if his like will pass this way again in our time."

**ARTHUR JOHN SCOTT PINCHIN, M.D.,
F.R.C.P. Lond.**

Dr. A. J. Scott Pinchin died at his home in Gledhow-gardens on Feb. 7th. He was in his sixtieth year and had been ill with pneumonia for only three days. Born at Sutton, Surrey, in 1877, the son of Alfred James Pinchin, oil broker, he was educated at Dulwich College and St. Thomas's Hospital from which he graduated in 1906, taking the gold medal in medicine at the London M.D. examination three years later. After holding house appointments at St. Thomas's, first as house physician to T. D. Acland, then as resident anaesthetist and casualty officer, Dr. Pinchin settled for a year or

two in general practice at Egham, Surrey, becoming an active member of the Windsor Medical Society and assistant school medical officer to the L.C.C. But he soon decided to devote himself to consulting work in diseases of the chest, and to this end he secured positions on the honorary staff of the Hampstead General Hospital, the West London Hospital, and the Victoria Park Chest Hospital, to

DR. SCOTT PINCHIN

two of which at the time of his death he was senior physician. He also took charge of the tuberculosis dispensary at Hampstead and was consulted by the New End Poor-law Hospital at Hampstead and the Maidenhead Hospital.

All this work, combined with a considerable private practice, kept him more than fully occupied for 25 years, only broken by a period during the war when he had charge of the officers' hospital at Imtarfa, Malta. Dr. Pinchin was an exceptionally good diagnostician and a sound practical physician, skilful in the use of instruments and quick to see their possibilities in modern medicine. He took charge of the electrocardiograph department when it was started at Victoria Park; after the war he was early in the field with the use of the thoracoscope, and with his junior colleague, Dr. H. V. Morlock, founded the bronchoscopic clinic at the same hospital. Despite indifferent health he was an indefatigable worker, devoted to the hospital side of his work, and popular with his house staff to whose assistance he was always ready to come in trouble. Almost his last act before he was taken ill was to attend a former resident in a rapidly fatal attack of pneumonia.

"Scott Pinchin," a colleague writes, "was a very lovable person and I doubt if he had an enemy in the world. He was a man of deep religious convictions, quiet and self-effacing. A shy and rather nervous manner made him avoid formal lecturing and public speaking as far as possible. He will be

remembered by his colleagues for sterling worth and a gift of friendship."

He wrote a good deal at various times, mostly in medical journals, covering at first a wide range of intrathoracic subjects but later concentrating chiefly on chronic pulmonary suppuration. His last contribution to our columns in June, 1935, concluded a series of papers, written over many years with Dr. Morlock, dealing with abscesses of the lung. "From small collections of clinical impressions such as these," he quoted modestly, "it may become possible in time to obtain an individual experience which will bring to bear at the right moment all the weapons available for use in this distressing condition." But he was writing from an experience of 2000 bronchoscopies over a period of four years, which has added substantially to our knowledge and for which clinical medicine is in debt to his memory.

Dr. Scott Pinchin married Miss Margaret Johnson, daughter of David Johnson, a well-known inventor, who survives him. There were no children of the marriage.

JOHN HENRY WILLIAMS, L.S.A., M.P.

THE death is announced as occurring on Feb. 7th of Dr. John Henry Williams, Member of Parliament for the Llanelly division of Carmarthen. Dr. Williams, by birth a Liverpool man, received his medical education at the Cardiff Medical School and the London Hospital and was for a time medical officer in the Booth Line. When he eventually settled in Wales at Burry Port he became a prominent practitioner and energetic in public causes. He was chairman first of the Burry Port district council and later of the Carmarthenshire county council and took a leading part in the promotion of the general health of the county and also in child welfare work. A Socialist in politics he had represented Llanelly in the House of Commons for more than 12 years, a proof of considerable determination on his side, for he was not successful until his fourth attempt in 1922; but having obtained admission to the House he stood the brunt of future contests and at the general election of November last was returned unopposed. From this short record it will be clear that in Dr. Williams his community has lost a valuable servant.

DR. WILLIAMS

**WILLIAM HENRY RUSSELL FORSBROOK,
M.D. Lond.**

THE death was announced in our columns last week of Dr. William Forsbrook, a well-known practitioner in the Eaton-square district. A prominent student at the Westminster Medical School where he was Chadwick prizeman and Bird medallist, he took the diplomas of L.S.A. and M.R.C.S. Eng. and graduated with honours as M.B. Lond. in 1878, later proceeding to the M.D. degree. Before going into

private practice he held the resident posts at the Westminster Hospital and was also surgical registrar. He was a frequent adviser to medical men proposing to practise in South Africa. He died on Feb. 3rd aged 85.

THE LATE SIR JOHN MARNOCH

Emeritus Professor J. A. MACWILLIAM, F.R.S., sends the following personal appreciation of Sir John Marnoch of whom an obituary notice appeared last week :—

"Far and wide the news of Sir John Marnoch's death will reach, and everywhere touch responsive chords of deep sympathy and awaken many memories. My own mind goes back to the time, more than forty years ago, when I was so fortunate as to have his able assistance in the work of the physiology department at Aberdeen after his brilliant student career. It is grievous to think now that his fine record has come to the end. Until he was suddenly stricken by illness some three years ago he looked very young for his age; whether seen at his work or in his ideally happy hospitable home, his slender alert figure and his keen vitality and notable zest in life gave every promise of many active years still to come. The

decline of his physical strength in recent time he accepted in the fine impersonal spirit characteristic of the man. Superb operator as he was, quiet, quick, and infinitely dexterous, what was still rarer was a supreme gift of wise and balanced judgment in dealing in comprehensive and far-sighted fashion with the various considerations of complex and difficult problems. His clarity of thought was remarkable. When an involved subject had been dealt with by Marnoch it came out shorn of all non-essentials, reduced to its simplest terms and expressed in a minimum of precise and lucid sentences.

"Marnoch was a gifted musician, his strikingly beautiful hands equally at home on the violin and with the scalpel. As a golfer and a salmon fisher on the reaches of his beloved Spey he was keen and skilful—an artist in all that he touched, whether work or recreation. His great success never changed John Marnoch in the least; his simplicity, absolute sincerity, and innate modesty were conspicuous in him while life lasted. Endlessly willing and most generously helpful, with a gift of leal-hearted friendship, his memory will ever be cherished by all who knew him and had to do with him as colleagues, students, patients, or friends."

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Advertisement of Medicines and Surgical Appliances

IN the ballot of private Members of the House of Commons for the right to present Bills which will come up for second reading on Fridays between now and Easter which took place on Feb. 6th Mr. G. A. V. DUCKWORTH (Shrewsbury, Unionist) was one of the first eight names in the ballot. The Bill which he proposes to bring forward is entitled the Medicines and Surgical Appliances (Advertisement) Bill. The measure is the outcome of the work of a committee representative of the various interests connected with the trade in proprietary medicines, and aims at the removal of some of the worst abuses in the advertising of those articles. Among the deputation which presented the Bill to the Minister of Health were representatives of local authorities, the British Medical Association, the Society of Medical Officers of Health, the Parliamentary Medical Committee, the Parliamentary Committee on Food and Health, newspaper and advertising associations, the Pharmaceutical Society of Great Britain, and bodies representing the drug trade, manufacturers of surgical instruments, and the Proprietary Association of Great Britain. The prohibitions in the Bill extend only to certain types of advertising. No one is prohibited by the Bill from treating any ailment or from supplying any medicine or appliance. Certain ailments and conditions are specified, and restrictions are imposed upon certain methods of "holding out" medicines, appliances, or treatment as beneficial to those suffering from them. The Minister of Health may remove any of the specified ailments or conditions from the operation of the Act, but he may not add new ones.

THE OFFENCE OF "HOLDING OUT"

According to an explanatory memorandum drawn up by the promoters of the Bill it is proposed to make it illegal in connexion with the supply or offer of a medicine or appliance or treatment to hold it out as effective for the cure or for the prevention or for exercising any salutary influence on any of the following ailments :—

(a) Bright's disease, cancer, consumption, diabetes, epilepsy, fits, locomotor ataxy, lupus, or paralysis.

It would also be illegal in connexion with the supply or offer of a medicine or appliance or treatment to hold it out as effective for any of the following purposes :—

(b) The cure of amenorrhœa, hernia, blindness, any structural or organic ailment of the auditory system, habits associated with sexual excess or indulgence, and any ailment associated with those habits; (c) procuring miscarriage of women; (d) the promotion of sexual virility in men or of sexual desire in women.

It would be illegal for the proprietor or distributor of a medicine or appliance and for a person administering treatment to publish a document which to his knowledge contains an intimation that any person is prepared to treat by correspondence any of the ailments or conditions mentioned under (a), (b), (c), and (d). The ailments referred to are those for which the Select Committee on Patent Medicines in 1914 recommended that advertisements for cure should be prohibited. In the Bill, the prohibition is extended to advertisements claiming effectiveness for prevention and for exercising a salutary influence on the course of those mentioned under (a).

EXCEPTIONS TO THIS OFFENCE

A "holding out" which would otherwise be illegal would be permitted in the following circumstances :—

(a) By a duly qualified medical practitioner or a registered dentist in the exercise of his profession; (b) if it is directed to doctors, dentists, nurses, pharmacists, hospitals, and persons carrying on a business including the practice of medicine or dentistry, or the supply of medicines or appliances; (c) in technical publications; (d) in connexion with patent applications; (e) to a patient for whom the medicine, appliance, or treatment has been prescribed by a doctor or dentist.

Certain advertisements for articles of diet which would otherwise be illegal are proposed to be permitted. But the claim made must be no more than that, as an article of diet and not otherwise, the article is effective for the preventing or exercising a salutary influence on (but not curing) any of the ailments mentioned under (a).

A person who publishes or delivers any document which the Act makes illegal commits an offence unless he can show that he delivered it in a package containing a medicine or appliance in the form in which it was supplied to him.

DIAGNOSIS OR TREATMENT BY CORRESPONDENCE

Invitations to correspond with a view to diagnosis or treatment may not be issued by the proprietor or distributor of a medicine or appliance or a person who administers treatment. It is illegal for such a person to publish any document which to his knowledge intimates that any person is prepared to diagnose by correspondence or to receive a statement of symptoms of ill-health with a view to advising for treatment by correspondence.

It is, however, permissible to advertise that a person will receive from someone who states that he knows himself to be suffering from a particular ailment particulars with a view to the supply of some article for its treatment. No such advertisement may refer to any of the ailments included under (a) or to amenorrhoea or to blindness. It is to be noted—

(1) That the offence is the publication of a document; (2) that the intimation must be for *treatment by correspondence*; (3) that the ailments and conditions to which the prohibition applies are limited.

No prosecution can be instituted without the consent of the Attorney-General.

SAVING CLAUSES

There is a saving clause for proprietors, publishers, printers, and distributors of newspapers and periodicals; for printers and distributors of circulars and other documents; for advertising agents; and for the employees of any of them. None of them is liable to be convicted of an offence under the Act if in the ordinary course of his particular business he has taken part in the publication of an advertisement which is illegal under the Act.

There is a further saving clause for a person professing a religious belief in the effectiveness of some means other than medicines or appliances for curing or preventing or exercising a salutary influence upon any of the ailments included under (a) or for curing any of the habits included under (b) in para. 2 of this memorandum. He may hold out the means as being effective for that purpose or he may publish an intimation that someone is prepared to employ that means for that purpose by correspondence. But to avail himself of this defence he must show to the satisfaction of the court that he is acting in accordance with the principles and practice of a religious body comprising a substantial number of persons resident in the United Kingdom who profess that belief, and also that he is authorised in accordance with the constitution of that body to act in that way. This exemption is to cover such treatment as "faith-healing" or prayer. To prevent the rogue taking shelter under it, it is limited to members of organised religious bodies, as, for example, Christian Scientists and Spiritualists.

In the House of Commons on Friday, Feb. 7th, Mr. DUCKWORTH presented the Medicines and Surgical Appliances (Advertisement) Bill which was set down for second reading on March 27th.

In the House of Lords on Thursday, Feb. 6th, the Royal National Pension Fund for Nurses Bill was presented and read a first time.

On Monday, Feb. 10th, in the House of Commons, Mr. TINKER presented the Public Health (Coal Mines Refuse) Bill, the object of which is to amend the Public Health Act, 1875, with respect to coal mine refuse liable to spontaneous combustion.

In the House of Lords on Tuesday, Feb. 11th, the report of Amendments to the Voluntary Hospitals (Paying Patients) Bill was agreed to on the motion of Lord Luke.

HOUSE OF COMMONS

WEDNESDAY, FEB. 5TH

Departmental Inquiry into Workmen's Compensation

Mr. TOM SMITH asked the Home Secretary what progress was being made by the departmental committee inquiring into certain matters connected with the Work-

men's Compensation Act.—Mr. GEOFFREY LLOYD, Under-Secretary of State for the Home Department, replied: I understand that the committee have had several meetings and taken a substantial amount of evidence. A good deal more, however, remains to be heard, and it is not possible at present to forecast when the inquiry is likely to be completed.—Mr. BURKE: Will the hon. gentleman take into consideration the very great difficulty that workmen suffering from silicosis have in making a claim under the Compensation Act?—Mr. LLOYD: That is a matter for the committee.

THURSDAY, FEB. 6TH

Protection of Life from Fire

Mr. GRAHAM WHITE asked the Minister of Health (1) if his attention had been drawn to the loss of life due to recent outbreaks of fire in Edinburgh and Tyldesley; and whether, in view of the fact that in these and other cases escape from burning buildings had been prevented by the destruction of staircases, he would in future, where possible, prescribe and elsewhere recommend that staircases should be constructed from fireproof material; and (2) if it was his intention to introduce legislation for the better inspection of buildings, with a view to reducing the risk of life and damage from fire to a minimum.—Sir K. WOOD replied: My attention has been called to the outbreaks of fire referred to. I have no power to prescribe the method of constructing staircases, but local authorities can deal with the matter by by-laws and have various powers of inspecting buildings. I will consider whether it is desirable to issue any recommendation to local authorities.

Grants for Water-supply

Mr. WELLS asked the Minister of Health (1) the number of applications received in respect of water-supplies and the total amount of grants up to the end of January last, and also the number of grants that had been given for areas where the rates, previous to a proposed scheme, had been under 10s. in the £; and (2) the total number of cases in which applications for grants in respect of water-supplies had been refused.—Sir K. WOOD replied: Up to the end of January last applications had been received in respect of 876 schemes relating to 2227 parishes. Grants totalling £831,000 had been provisionally allocated in respect of 550 schemes for 1707 parishes, including 182 schemes where, previous to the proposed scheme, the rates were less than 10s. in the £. Grants had been refused in respect of 190 schemes on the ground that they were not needed to enable the schemes to be carried out.

Nutrition Surveys

Mr. JOEL asked the President of the Board of Education whether, in view of his departmental circular on free meals and free milk for underfed school-children, he could state whether any education authorities were acting on his advice to hold periodically nutrition surveys at which all children not receiving free meals would be passed under review; and whether he could give the names of such authorities.—Mr. OLIVER STANLEY replied: I understand that certain local education authorities have acted, or propose to act, on the Board's suggestions that periodical nutrition surveys should be held at which children not receiving meals would be passed under review. I am afraid however that I have no information about the number of these authorities, but I understand that the areas in which complete or partial surveys have been or will be held include Swansea, Gateshead, Norwich, Liverpool, and Workington.

Spa Treatment for Health Insurance Patients

Mr. MANDER asked the Minister of Health if he would consider the desirability of arranging that spa treatment should be an additional benefit under national health insurance.—Sir K. WOOD replied: The present list of additional benefits affords to approved societies a wide variety of forms of remedial treatment, and in fact the surplus funds of societies available as a result of the last valuation have already been allocated on this basis. The addition of spa treatment was considered but was not selected. If before the date of the next valuation I have evidence that there is a fairly widespread desire

on the part of societies for the suggested addition, I will give the matter further consideration. Mr. MANDER: Has not the right hon. gentleman recently had a good many representations from societies on this subject? Sir K. WOOD: Yes, Sir, that is so.

Typhoid Fever in Derbyshire

Mr. HOLLAND asked the Minister of Health if he was aware that an outbreak of typhoid fever was affecting a number of persons residing in the village of Langwith, Derbyshire, in the area controlled by the Blackwell rural district council; and what steps had been taken to deal with the matter.—Sir K. WOOD replied: The answer to the first part of the question is in the affirmative. As regards the second part, on the recommendation of my department the previous source of the water-supply to this village has now been abandoned in favour of one which, it is believed, is free from pollution, and I hope that there will be no recurrence of the outbreak.

Mr. HOLLAND asked the Minister of Health if his attention had been drawn to the frequent floodings from a canal on one side and a polluted river on the other of houses situate in Meadow Rams, Pinxton, Derbyshire, endangering the health of the inhabitants and giving rise to great inconvenience; and was he satisfied that proper progress was being made by the Blackwell rural district council in dealing with the matter.—Sir K. WOOD replied: My attention has not previously been drawn to this matter. I will make inquiries.

Mental Treatment

Mrs. TATE asked the Minister of Health what was the increase, if any, in proportion to the population, in the number of persons receiving mental treatment in private homes and State and voluntary hospitals, in the years 1900, 1920, 1930, and 1935 respectively; and whether there was in every case sufficient accommodation for those requiring treatment.—Sir K. WOOD replied: The number of persons per 10,000 of population receiving mental treatment in the places indicated was 25.4 in 1900; 26.3 in 1920; 31.3 in 1930; and 32.8 in 1935. The answer to the second part of the question is in the affirmative, except that in 1930 and 1935 the number of beds available in some public mental hospitals was not sufficient to enable the prescribed standards of bed space to be fully observed. Local authorities in the areas concerned are now actively engaged in providing additional accommodation where needed.

Workmen's Compensation: Medical and Legal Expenses

Mr. T. SMITH asked the Home Secretary whether he would arrange that in future annual statistics on workmen's compensation, legal and medical expenses should be shown as separate items.—Mr. G. LLOYD replied: The returns under the Workmen's Compensation Act on which the annual Home Office statistics are based cover only the compensation paid, and I am afraid that there would be great difficulties in the way of obtaining the amount of the legal and medical expenses incurred by the various parties concerned. So far as regards insurance companies I understand that for the group belonging to the Accidents Offices Association, which includes most of the larger companies, legal expenses are estimated at 2½ per cent. and medical expenses at 1¼ per cent. of the premium income.

MONDAY, FEB. 10TH

Bombing of Red Cross Units in Abyssinia

Mr. WATKINS asked the Secretary of State for Foreign Affairs whether he had any information on how many occasions since the outbreak of hostilities Italian aircraft had bombed Red Cross units in Abyssinia; and whether any British Red Cross units or British subjects serving with Red Cross units had been attacked in this way.—Mr. EDEN replied: According to such information as is available, I understand that the American hospital at Dessie was bombed on Dec. 6th last. On Dec. 30th the Swedish ambulance operating with the Ethiopian forces on the southern front was virtually destroyed by aircraft near Dolo, and on Jan. 4th Ethiopian Red Cross Ambulance No. 1, whose staff includes two British subjects, was bombed and machine-gunned near Dagabur. The

one wholly British ambulance now serving in Ethiopia has not suffered as the result of Italian air action.

Dialling of Emergency Telephone Calls

Mr. DAY asked the Postmaster-General whether, in view of the delay caused at times when dialling O on the automatic telephone exchange in the case of an emergency, he would consider with his engineers whether another dialling signal could be substituted on all automatic exchanges direct to fire, police, and ambulance stations; and if he could say how long it would take to make this alteration in the present telephone equipment, and what would be the estimated cost.—Major TRYON replied: I recently appointed a committee to consider the best means of securing the rapid setting up of emergency telephone calls; and I am afraid it would be difficult to frame estimates such as the hon. Member asks for before receiving their recommendations.

Milk Designations Draft Order

Mr. THOMAS WILLIAMS asked the Minister of Health how many protests had been received by his department concerning the revised draft order, special designations for milk; whether he was aware of the general opposition of all producers of Certified milk and all those agencies who were trying to improve the standard and quality of milk; and if he would consult with interested bodies before the revised draft order came into force.—Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Health, replied: My right hon. friend has received very few representations with regard to the revised draft Milk (Special Designations) Order which was published on Jan. 24th. The answer to the second part of the question is in the negative. It is open to any interested parties to make representations to my right hon. friend upon the draft within 40 days of its publication and any such representations will receive full consideration.

Duties of Nurses in Mental Hospitals

Sir FRANCIS FREMANTLE asked the Minister of Health what were the orders or regulations governing off-duty hours and facilities for nurses in mental hospitals; and whether he would inquire into their adequacy, considering the special need in such occupation of daily and weekly change of environment.—Sir K. WOOD replied: The hours of duty and conditions of service for nurses in mental hospitals are determined by the visiting committees of those institutions. The majority have adopted the scheme recommended by the joint conciliation committee representing employers and nurses. An increasing number of local authorities are providing change of environment and recreational facilities by establishing nurses' homes for mental hospital staffs. I am not aware of circumstances indicating the necessity for an inquiry, but if my hon. friend has particular cases in mind, perhaps he will communicate with me.

Resident Chaplains in Mental Institutions

Sir FRANCIS FREMANTLE asked the Minister of Health whether, in view of the value of intelligent and sympathetic ministers of religion in the treatment of mental disease and deficiency, he would take steps to promote the appointment in mental institutions of resident chaplains suited and qualified for the work.—Sir K. WOOD replied: The appointment of whole-time or resident chaplains is within the discretion of the authorities owning mental institutions. The importance of such appointments in large mental hospitals was emphasised in the report of the Board of Control issued last year, and the matter will be brought to the notice of individual authorities as opportunity occurs. I am not, however, empowered to give any direction in the matter.

Milk Act, 1934, to Remain in Force

Sir EDWARD RUGGLES-BRICE asked the Minister of Agriculture what action the Government proposed to take when the main provisions of the Milk Act, 1934, expired at the end of March.—Mr. ELLIOT replied: For several reasons, including the currency of various trade agreements and the fact that the report of the Reorganisation Commission for Milk for Great Britain is not likely to be published for some time to come, it is not possible at present to bring before Parliament long-term legislation for the milk industry. In order to allow adequate time

for the consideration by all parties of the important questions at issue, the Government have decided to ask Parliament to continue until the end of September, 1937, the main provisions of the Milk Act, 1934. A Bill to give effect to this decision will be introduced forthwith.

TUESDAY, FEB. 11TH

Loss of Dangerous Drugs and Poisons

Sir JOSEPH LAMB asked the Home Secretary whether his attention had been called to the increasing number of cases where dangerous drugs and poisons had been lost in transit or stolen from unattended vehicles and to the danger caused thereby to the general public; and what action, if any, he proposed to take in the matter.—Sir J. SIMON replied: There is, I think, no reason to suppose that there has been any increase in the number of such cases, though they have had more publicity of late by reason in particular of the fact that broadcasting is now employed when a loss or theft of this kind is reported to the police and it is thought necessary that the public should be warned by this means. The remedy seems to lie in the exercise of more care and good sense by those concerned, and I hope that the wider publicity will help to achieve that result.

Sir JOSEPH LAMB asked whether, if that did not bring about the desired result, the Home Secretary would bring in more stringent regulations to prevent these happenings.

Sir JOHN SIMON said the hon. Member would see that there would be danger, if they were not careful, of restraining persons from reporting such losses for fear of the consequences to themselves. It was much better that they should report the loss quickly, then the police could be helpful.

Medical Attendance of Arrested Persons

Mr. JAGGER asked the Home Secretary what were the regulations governing medical attendance on persons

detained under arrest at police stations pending appearance before the magistrates; and if he would say whether such arrested persons had the right to see a doctor on request.—Mr. GEOFFREY LLOYD, Under-Secretary, Home Office, replied: All police forces have instructions to take special care in regard to the treatment of prisoners suffering from illness, to call a doctor to examine any prisoner who complains of illness or shows symptoms of being in a feeble state of health, and to have him removed to hospital if the doctor thinks it necessary. If such a person wished to call in a doctor selected by himself, steps would be taken to meet his wishes if possible, but the police would not wait for a request or complaint from him if they considered that he needed medical attention.

Variola Minor

Mr. BROMFIELD asked the Minister of Health whether he would consider the advisability of making a special investigation of the circumstances attending the outbreak of variola minor which prevailed in certain limited areas of this country during the years 1922–34, with a view to ascertaining what were the causes of its greater incidence in mining areas and whether the disease affected mainly those areas where infant vaccination had declined most.—Sir K. WOOD replied: During the years referred to in the question small-pox occurred in no less than 49 of the 61 counties in England and Wales. The circumstances in which the disease occurred were described in the annual reports of the chief medical officer of my department, and also in a review published in 1931 entitled "A Review of Certain Present Aspects of Small-pox Prevention in relation particularly to the Vaccination Act, 1867 to 1907." The published reports contain full statistics as to the numbers of vaccinated and unvaccinated children, respectively, who contracted the disease, and they afford ample evidence of the value of vaccination as a preventive of the disease. In these circumstances I do not think that any special investigation is necessary.

MEDICAL NEWS

University of Cambridge

The degree of bachelor of medicine has been conferred on W. A. Law and the degree of bachelor of surgery on K. G. F. Mackenzie.

University of London

Four lectures on the endocrine organs in relation to metabolism will be given by Dr. C. Reid on Mondays, March 2nd, 9th, 16th, and 23rd, at University College, Gower-street, W.C., at 5 P.M. The lectures are open to all.

University of Glasgow

On Wednesdays, Fridays, and Mondays from April 15th, in the ophthalmic department of the University, Prof. Arthur Brückner, of Basle, is giving six lectures on physiological optics and their relation to clinical ophthalmology and special clinical ophthalmological problems.

Royal College of Physicians of Edinburgh

A quarterly meeting of the college was held on Feb. 4th with Dr. W. T. Ritchie, the president, in the chair, when Dr. John Philip Cameron (Edinburgh) was introduced and took his seat as a fellow, and Dr. Prag Nath Kapur (Delhi) and Dr. Venkatasubha Mahadevan (Madras) were elected to the fellowship.

Dr. J. G. Greenfield was appointed the Morison lecturer for 1936, Sir Thomas Lewis the George Alexander Gibson lecturer for 1936, and Dr. J. D. Gilruth the Dr. Alexander Black lecturer for 1936.

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty held on Feb. 3rd, with Prof. Archibald Young, the president, in the chair, Dr. Sailes Chandra Guha, of Rangoon, was admitted to the fellowship.

Royal Microscopical Society

At a meeting of this society at B.M.A. House, Tavistock-square, London, W.C., at 5.30 P.M. on Wednesday, Feb. 19th, Dr. G. M. Findlay will read a paper on a new virus disease of mice.

Grants for Scientific Investigations

Particulars of government grants for scientific investigations may be obtained from the clerk to the government grant committee of the Royal Society, Burlington House, London, W.1, and applications should be sent to him not later than March 31st.

Lectures in Hospital Administration

A three months' course of lectures and demonstrations on clinical practice and hospital administration will be given by Dr. J. V. Armstrong at the Brook Hospital, Shooters Hill, Woolwich, S.E., on Mondays, Wednesdays, and alternate Saturdays, beginning on Wednesday, April 1st. Further particulars may be had from the medical officer of health of the London County Council, Public Health Department (Special Hospitals), County Hall, S.E.1.

The Cost of Superstition

The serpent, emblem of the healing art, twined round a staff on the tower of East Grinstead's new hospital is probably to be removed, because it is thought to have brought bad luck to the hospital. The institution was opened less than a month ago and, according to a correspondent in the *Times*, two patients have already died in hospital, the matron has been ill, and it is now recalled that the rain fell in torrents on the day of the opening. It will cost £60 to remove the serpent.

Tuberculosis Conference

The twenty-second annual conference of the National Association for the Prevention of Tuberculosis will be held at the County Hall, London, from July 16th to 18th, under the presidency of Sir Robert Philip, chairman of the council of the association. Subjects for discussion will include: examination of contacts; protection of the adolescent and young adult from tuberculosis; tubercle-free herds; and the need for closer coöperation between the tuberculosis service and the maternity and child welfare service, and possibly the educational authorities. The secretary may be addressed at Tavistock House North, Tavistock-square, London, W.C.1.

Sir Aldo Castellani has been appointed medical adviser to the King of Greece. He is at present on a tour of inspection of the Italian forces in Abyssinia.

Oldham Municipal Hospital

It is proposed to spend £30,000 on enlarging this hospital, as about 40 more beds are required in the general section.

New Health Clinic for Wellington

A new public health clinic has been opened by Lady Forester at Wellington. Part of the clinic will be used for tuberculosis cases and provision has been made for orthopaedic after-care treatment.

Guild of Hospital Librarians

The second annual meeting of this association will be held from May 8th to 11th in La Salle Debussy, 8, Rue Daru, Paris, under the chairmanship of Dr. René Sand. Further information may be had from Mrs. M. E. Roberts, hon. secretary of the guild, 48, Queen's-gardens, London, W.2.

Poisons for Rodents

The University of London Animal Welfare Society is holding a discussion on this subject at the College of the Pharmaceutical Society, 17, Bloomsbury-square, London, W.C., at 5.30 p.m., on Thursday, Feb. 27th. The object of the discussion is to explore the feasibility of selecting and devising poisons with a view to humane considerations. Mr. J. G. Wright, F.R.C.V.S., will deal with the pathological effects of poisons, Mr. J. D. Hamer, F.I.C., will describe chemical rat-control in ships and docks, and Mr. T. Howard will speak on poisoned baits. The general discussion will be opened by Mr. G. D. Lander, D.Sc., and Prof. J. H. Burn, M.D., will be in the chair. Medical practitioners who wish to attend should inform the hon. secretary of the society, 42, Torrington-square, W.C.

Medical Congresses at Wiesbaden

The 27th meeting of the Deutsche Röntgen-Gesellschaft is to be held at Wiesbaden on March 26th, 27th, and 28th, under the presidency of Prof. Hans Dietlen. The first two days of the meeting will be devoted to diagnostic radiology and short-wave therapy, while on the last day physical and technical problems will be discussed. The 48th meeting of the Deutsche Gesellschaft für Innere Medizin is being held at Wiesbaden from March 23rd to 26th under the presidency of Prof. Schwenkenbecher, and on the 26th a joint meeting of the two societies will take place. Dr. Karl Frik, Brückenallee 22, Berlin, N.W. 87, is the secretary of the radiological congress.

Maternal Mortality and Abortion

On Feb. 11th Sir Kingsley Wood, the Minister of Health, received a deputation from the National Council of Women of Great Britain. Its object was to submit to the Minister a resolution urging (1) that the Government should appoint a representative committee to inquire into the incidence of abortion and as to the law and its administration dealing with criminal abortion and attempted abortion, and to consider what measures, if any, are advisable to improve the existing position; and (2) that future official returns should show the deaths attributable to abortion separately from the general figures for maternal mortality. The Minister said in his reply that the high rate of maternal mortality in certain districts had, for some time, been under investigation by medical officers of the Ministry, and before considering any further inquiry he would prefer to await their report, which he hoped to receive before the end of the year. He nevertheless promised that the deputation's statements would be examined to see if any action could usefully be taken in advance of the report. The problem was largely a social one, and he was determined to press on with the measures for slum clearance and abatement of overcrowding on which a good start had already been made. He would also continue to press local authorities to improve their maternity and child welfare services, and particularly to provide adequate antenatal care for pregnant women. A Bill to improve the midwifery service was about to be introduced.

Dr. George Leslie Milburn has been appointed an official member of the Legislative Council of the Presidency of St. Christopher and Nevis.

Society of Radiotherapists

This newly formed society will hold its first clinical meeting at the rooms of the Medical Society of London (11, Chandos-street, W.) on Friday, Feb. 21st, at 4.30 p.m. Mr. Geoffrey Keynes and Dr. W. M. Levitt will open a discussion on the technique of radiotherapy in carcinoma of the breast which has not been previously treated. The hon. secretary of the society is Dr. B. W. Windeyer, Middlesex Hospital, London, W.1.

Tribute to Medical Officer

At a recent meeting of the town council Dr. James Gairdner, who for 56 years has been medical officer for Crieff, received the congratulations of the burgh on attaining his 90th birthday. Dr. Gairdner has always taken a special interest in industrial diseases, and as long ago as 1895 described in his annual report valuable investigations into the composition of metallic furnes and the effects of manganese poisoning.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Feb. 18th.

Medicine. 5 p.m. Dr. Otto Leyton: The Morbid Conditions which Cause Progressive Hyperglycaemic Glycosuria and the Circumstances which Modify its Course. Dr. J. Graham Willmore, Dr. H. P. Hims-worth, and Dr. T. C. Hunt will also speak.

General Meeting of Fellows. 5.30 p.m.

Ballot for election to the Fellowship.

Pathology. 8.15 p.m. (London School of Hygiene, Keppel-street, W.C.) Sir Rickard Christophers: 1. Specimens illustrating *B. knoeckii* (the Parasite of Monkey Malaria). Dr. I. N. Asheshov; 2. Technical Methods Used in Investigation of the Bacteriophage. J. C. Cruickshank; 3. *Bact. typhiflavum*. H. Schwabacher; 4. Desensitisation of Tuberculin-sensitive Guinea-pigs. E. A. Straker; 5. Solubility of Pneumococci in Sodium Hydrate. G. S. Wilson; 6. Modified Methylene Blue Test for the Grading of Milk. 7. Rapid Method for the Quantitative Enumeration of *Bact. coli* and *Bact. aerogenes* in Water.

THURSDAY.

Dermatology. 5 p.m. (Cases at 4 p.m.) Dr. H. W. Barber: 1. Keratosis Pilaris Atrophicans (previously shown). Dr. F. F. Hellier (for Dr. H. W. Barber); 2. Urticaria Pigmentosa. Dr. G. B. Dowling; 3. Schamberg's Disease. Dr. W. J. O'Donovan; 4. Lupus Erythematosus Treated by Radium. Dr. G. W. Bamber; 5. Fibroma with a Typical Epithelial Proliferation. Dr. Elizabeth Hunt; 6. Sebocystomatosis.

Neurology. 8.30 p.m. (Cases at 8 p.m.) Dr. T. Tennent: The Diagnosis and Treatment of Congenital General Paralysis. Dr. J. Brander, Dr. W. D. Nicol, and Dr. R. M. Stewart will also speak.

FRIDAY.

Obstetrics and Gynaecology. 8 p.m. Dame Louise McIlroy: Atresia of the Vagina Operation followed by Pregnancy and Caesarean Section. Mr. A. A. Davis: Intrinsic Dysmenorrhœa. Mr. Malcolm Donaldson, Mr. V. B. Green-Armytage, Mr. Chassar Moir, Mr. B. P. Wiesner, Ph.D., and Prof. James Young will also speak.

Radiology. 8.15 p.m. Prof. H. Chaoul (Berlin): Some Recent Developments in X-ray Therapy. Prof. J. M. Woodburn Morison and Dr. J. F. Bromley will also speak.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.

MONDAY, Feb. 17th.—9 p.m., Dr. P. H. Manson-Bahr: The Differential Diagnosis of Diseases of the Colon (Dysentery and Colitis) and their Complications (first Lettsomian lecture).

CHELSEA CLINICAL SOCIETY.

TUESDAY, Feb. 18th.—8.30 p.m. (Hotel Rembrandt, Thurloe-place, S.W.), Mr. Desmond MacManus and Mr. Cecil Rowntree: Consultations.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Thorn-lough-street, W.C.

FRIDAY, Feb. 21st.—5 p.m., Dr. W. M. Ash: Prevention of River Pollution.

Maternity and Child Welfare Group.—8.30 p.m., Dr. Andrew Topping: Certain Factors Influencing Maternal Mortality and the Part Played in Combating them. *Tuberculosis and Dental Officers' Groups.*—8 p.m., Discussion on Dental Treatment of Tuberculous Patients.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, Manson House, 26, Portland-place, W.
THURSDAY, Feb. 20th.—8.15 P.M., Dr. R. Lewthwaite: Recent Work on the Typhus-like Fevers of Malaya.

TUBERCULOSIS ASSOCIATION.
FRIDAY, Feb. 21st.—5.15 P.M. (Manson House, 26, Portland-place, W.), Dr. H. H. Scott and Dr. C. H. C. Toussaint: Primary Tuberculosis in Children and its Relationship to Meningitis. 8.30 P.M., Sir Henry Gauvain and Mr. G. R. Girdlestone: The Treatment of Tuberculous Lesions of Bones and Joints.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.
WEDNESDAY, Feb. 19th.—4 P.M. (St. James' Hospital, Ouseley-road, S.W.), Dr. George Graham: Treatment of Diabetes.

SOCIETY OF RADIO THERAPISTS.
FRIDAY, Feb. 21st.—4.30 P.M. (11, Chandos-street, W.), Mr. Geoffrey Keynes and Dr. W. M. Levitt: The Technique of Radiotherapy in Carcinoma of the Breast which has not been previously Treated.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.
MONDAY, Feb. 17th, **WEDNESDAY** and **FRIDAY**—5 P.M., Dr. John Beattie: Temperature Regulation (Arris and Gale lectures).

UNIVERSITY OF LONDON.
FRIDAY, Feb. 21st.—11 A.M. (London School of Hygiene, Keppel-street, W.C.), Dr. W. G. Savage: Food Poisoning.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.
WEDNESDAY, Feb. 19th.—4 P.M., Mr. A. Clifford Morson: Fads and Fancies in the Treatment of Prostatic Obstruction.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.
TUESDAY, Feb. 18th.—5.30 P.M., Dr. T. F. Cotton: Mitral Disease and its Treatment.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
WEDNESDAY, Feb. 19th.—2 P.M., Mr. James Crooks: Tonsils, Adenoids, and Accessory Air Sinuses. 3 P.M., Dr. A. Signy: Bacteriology of Tonsillitis.
 Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.

NATIONAL HOSPITAL, Queen-square, W.C.
MONDAY, Feb. 17th.—3.30 P.M., Dr. Kinnier Wilson: Some Heredo Familial Diseases (I.), Extra Pyramidal (II.).
TUESDAY—3.30 P.M., Dr. Critchley: Cerebral Vascular Disease (IV.).
WEDNESDAY—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.
THURSDAY—3.30 P.M., Mr. Leslie Paton: Optic Atrophy.
FRIDAY—3.30 P.M., Dr. Purdon Martin: Poliomyelitis.
 Out-patient Clinic daily at 2 P.M.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.
MONDAY, Feb. 17th.—10 A.M., Medical wards and skin clinic. 11 A.M., Surgical wards. 1.30 P.M., Gynecological wards. 2 P.M., Surgical wards, gynecological and eye clinics. 4.15 P.M., Mr. Green-Armytage: Sterility.
TUESDAY—10 A.M., Medical wards. 11 A.M., Surgical wards. 2 P.M., Throat clinic.
WEDNESDAY—10 A.M., Children's ward and clinic. 11 A.M., Medical wards. 2 P.M., Eye clinic. 4.15 P.M., Lecture on anaesthesia.
THURSDAY—10 A.M., Neurological and gynecological clinics. Noon, Fracture clinic. 2 P.M., Eye and genito-urinary clinics.
FRIDAY—10 A.M., Skin clinic. Noon, Lecture on treatment. 2 P.M., Throat clinic.
SATURDAY—10 A.M., Surgical and children's clinics, medical wards.
 Operations, medical and surgical clinics daily at 2 P.M.
 The lectures at 4.15 P.M. are open to all medical practitioners without fee.

ST. JOHN CLINIC, Ranelagh-road, S.W.
FRIDAY, Feb. 21st.—4.30 P.M., Mr. Martin Oldershaw: Some Chronic Causes of "Rheumatism" in Women.

LONDON SCHOOL OF DERMATOLOGY, 5, Lisle-street, W.C.
TUESDAY, Feb. 18th.—5 P.M., Dr. S. E. Dore: Pruritus, Prurigo, and Lichenification.
WEDNESDAY—5 P.M., Dr. I. Muende: Histopathology.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Feb. 17th, to **SUNDAY**, Feb. 23rd.—**CHELSEA HOSPITAL FOR WOMEN**, Arthur-street, S.W. All-day course in gynecology.—**NATIONAL TEMPERANCE HOSPITAL**, Hampstead-road, N.W. Tues., 8.30 P.M., Mr. R. Y. Paton: Deformities. Thurs., 8.30 P.M., Mr. David Patey: Liver, Spleen, and Pancreas.—**ST. JOHN'S HOSPITAL**, 5, Lisle-street, W.C. Afternoon course in dermatology.—**PRINCESS ELIZABETH OF YORK HOSPITAL**, Shadwell, E. Sat. and Sun., course in children's diseases.
 Courses are open only to members and associates of the fellowship.

LEEDS GENERAL INFIRMARY.
TUESDAY, Feb. 18th.—3.30 P.M., Mr. Pain: Common Foot Complaints in General Practice.

LEEDS PUBLIC DISPENSARY.
WEDNESDAY, Feb. 19th.—4 P.M., Dr. S. J. Hartfall: Influenza.

UNIVERSITY OF DURHAM.

SUNDAY, Feb. 23rd.—10.30 A.M. (Newcastle General Hospital), Mr. A. Logan: Surgical Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.
WEDNESDAY, Feb. 19th.—4.15 P.M. (Royal Infirmary), Dr. J. Ferguson Smith: Some Infective Diseases of the Skin.

Appointments

London County Council Hospital Staff.—The following appointments, promotions, and transfers are announced. A.M.O. (I.) and (II.)=Assistant Medical Officer, Grades I. and II.

SHEEHAN, J. P., M.D., M.R.C.P. Irel., A.M.O. (II.), Bethnal Green;

KIRMAN, B. H., M.B. Lond., A.M.O. (II.), Constance-road Institution;

YOUNG, R. M., M.D. Edin., A.M.O. (II.), Constance-road Institution;

RAMSAY, A. M., M.B. Aberd., A.M.O. (II.), Fulham;

JONES-DAVIES, T. E., M.R.C.S. Eng., A.M.O. (II.), Highgate;

DIMSON, S. B., M.D. Lond., D.T.M. & H., A.M.O. (II.), Highgate;

MCGREGOR, C. B., M.B. Glasg., D.P.H., High Wood Hospital for Children;

MATHESON, I. W., F.R.C.S. Eng., A.M.O. (II.), Mile End;

DICKIE, A. E., M.B. Glasg., A.M.O. (II.), Mile End;

SIMON, E. L., M.B. Lond., A.M.O. (II.), St. Charles';

FOX, R. W. S., M.B. Melb., A.M.O. (II.), St. Charles';

BOYLE, A. K., M.B. Glasg., A.M.O. (II.), St. George-in-the-East;

ROWLANDS, E. A., M.B. Melb., F.R.C.S. Eng., A.M.O. (I.), St. Mary, Islington;

MERSON, G. P., M.B. Aberd., A.M.O. (II.), St. Olave's;

LAWSON, W. S. G., M.B. Lond., A.M.O. (II.), St. Pancras;

TULLIDGE, G. M., M.B. Lond., D.T.M. & H., House Physician, High Wood Hospital for Children;

EVANS, W. G., M.B., D.P.H., House Physician, North-Western;

ORPWOOD, R. M. M. C., M.R.C.S. Eng., D.P.H., House Physician, Queen Mary's Hospital for Children;

PEARSON, H. E. S., M.B., M.R.C.P. Lond., A.M.O. (I.), St. Mary, Islington;

GREEN, R. D., M.B., M.R.C.P. Lond., A.M.O. (II.), St. Pancras;

FLATLEY, G. D., M.B. Belf., A.M.O. (I.), Mile End.

Certifying Surgeons under the Factory and Workshop Acts:
 Dr. W. F. MASON (Bradford (Cleckheaton) District, Yorks (West Riding)); Dr. R. MCC. PATERSON (Shepshed District, Leicestershire); Dr. R. L. UNSWORTH, (Westhoughton District, Lancashire); and Dr. GAVIN BROWN, (Mochrum District, Wigtown).

Births, Marriages, and Deaths**BIRTHS**

BARKER.—On Feb. 1st, at a nursing-home, the wife of Dr. A. N. Barker, Maidstone-road, N., of a son.

HOLMWOOD.—On Feb. 7th, at Aldermaston, Berks, the wife of L. S. Holmwood, M.R.C.S. Eng., of a son.

LEANING.—On Feb. 2nd, in Edinburgh, the wife of Capt. R. R. Leaning, R.A.M.C., of a daughter.

LEVI.—On Feb. 5th, at Woodchurch-road, N.W., the wife of David Levi, M.S. Lond., F.R.C.S. Eng., of Harley-street, W., of a daughter.

ORR.—On Jan. 25th, at Neyyoor, Travancore, India, the wife of Ian M. Orr, M.D. Glasg., F.R.C.S. Edin., of a son.

SHAW.—On Feb. 7th, at Welbeck-street, to Mary Michael Shaw, M.B., B.S., wife of C. C. Shaw, B.Arch., A.R.I.B.A.—a son.

SUTHERLAND.—On Jan. 31st, at Bath, the wife of Dr. Alister Sutherland, of a daughter.

MARRIAGES

GRIFFITHS-WRIGLEY.—On Feb. 1st, at the Congregational Church, Buxton, Griffith John Griffiths, B.Sc., M.B. Lond., of Colwyn Bay, to Nancy Bryceson Wrigley, elder daughter of Mr. W. F. Wrigley of Buxton.

STEVENSON-GLUCK.—On Feb. 1st, at London, John Black Stevenson, M.C., M.B. Glasg., of Sanderstead, Surrey, to Marie Gluck, daughter of the late I. Gluck, Esq., of London.

DEATHS

BALLANCE.—On Feb. 8th, at St. John's Wood Court, N.W., Sir Charles A. Ballance, K.C.M.G., M.S. Lond., F.R.C.S. Eng.

BOSWELL.—On Feb. 6th, at York-avenue, East Sheen, S.W., Alexander Boswell, M.D. Aberd., aged 82.

LEECH.—On Feb. 7th, 1936, Priestley Leech, M.D. Lond., F.R.C.S. Eng., the dearly loved husband of Emmie Milson Leech, in his 74th year. Was laid to rest in St. Paul's Churchyard, King Cross, Halifax, Feb. 10th, 1936.

MAITLAND.—On Feb. 6th, at Dudley, Vivian Gray Maitland, M.R.C.S. Eng., D.P.H. Dub., in his 58th year.

MILNER.—On Feb. 4th, in London, Major Arthur Edward Milner, M.R.C.S. Eng., late R.A.M.C., in his 68th year.

PINCHIN.—On Feb. 7th, at Gledhow-gardens, S.W., Arthur John Scott Pinchin, M.D., F.R.C.P. Lond., aged 59.

WILLIAMS.—On Feb. 7th, at Barry Port, Carmarthenshire, John Henry Williams, L.S.A. Lond., M.P., Carmarthenshire, Llanelly Division.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

FURNITURE FOR CONVALESCENCE

CONVALESCENT homes too often carry the hospital tradition into what should be a holiday atmosphere. At the new convalescent home for children, built under the Zachary Merton trust for the Royal Manchester Children's Hospital, the furniture has been specially designed by Heal's to please the imagination of the child returning to health. The beds are of iron, and run on strong wooden castors, but there their likeness to hospital beds ends, for the smooth half-moon of iron at the head and foot of each bed is coloured green with cellulose paint, and bears a fine large picture of a country flower—a different flower for each bed, painted by hand, not a single design transferred interminably. The cots are green, too, each again with its special flower, and both sides of the cot can be lowered smoothly with no crashing of hinges or damage to nurses' insteps. The beds are sprung with strong chain springs, impervious to bouncing, and in addition to a good hair mattress each child has a feather pillow and a pillow of feather and down. Over the beds are spread wool rugs designed in shades of green, and at every bedside is a cupboard of weathered oak with a towel rail and a green top of cork and rubber composition on which the evening milk can be spilt and not one tear need be shed about it. The dining tables and play tables of strong and simple pattern have the same perdurable surface, but in a colour in harmony with the weathered oak of which all the furniture is constructed. The sturdy chairs are in two sizes, for longer and shorter patients. In the day-rooms the large toy cupboards have half-moons of wood for handles and roomy shelves. The book-cases are low and stout so that they can be climbed upon without damage to themselves and fallen off without damage to the climber. Sun couches with adjustable backs, wheel-chairs, and glass cupboards and trolleys for surgical equipment are the only things which recall the hospital a little; but even the ironwork of the cupboard is painted green. The comfort of the nurses has been equally considered. Their box-spring beds have a little bookshelf in the oak headpiece and a concealed light under its upper border. Such furniture as this has a look of summer even on a February day, and fully carries out the determination of Messrs. Heal and Son to avoid the hospital atmosphere. It is on view at their show-rooms in Tottenham Court-road, London, until Feb. 21st.

CHEST RADIOGRAPHY

A YEAR ago Messrs. Watson and Sons, Ltd., invited inspection of a new condenser set for radiography of the chest. One of these sets, installed on approval in a London hospital, has taken about 12,000 radiograms with little trouble and much efficiency. The principle of the condenser discharge is not new but has been revived in this set owing to the large current that can now be passed through a Rotalix tube for a thirtieth of a second without damage to the focus. The set is shock proof, the mechanical parts and tube being totally enclosed in a metal cabinet. It takes up 6 ft. 5 in. by 2 ft. 11 in. by 9 ft. 2 in. high. The advantages of this type of construction are briefly: (1) it is simple in operation; (2) variation in film density is controlled solely by variation of kilo voltage; (3) no time switch is required; (4) patients, no matter of what size, can be radiographed in the same exposure time of 1/30 sec.; (5) the level of the tube from the floor is fixed, the patient being centred by raising or lowering a platform electrically.

The quality of the radiographic detail is of a high order, showing a "soft" picture with a wealth of detail. Nine variations of penetration are provided, a "tail" being provided which gives a slightly increased exposure time per stud. In practice it is found that studs Nos. 1 and 2 are of no value. No. 3 has been used for children, 4, 5, and 6 for normal

adults according to their thickness, studs 7, 8, and 9 only being required for stout patients. Anterior views are taken at a distance of 5 ft., since at this distance the machine gives the requisite blackening in a patient of average build. The hope of obtaining views of comparable density in radiograms of the same subject taken at intervals was not realised, although it would be unfair to attribute such difference as arises to the set itself when other factors are present such as alteration in weight of the patient, change in dark-room technique, or screen speed.

Certain disadvantages have been noticed in practice: (1) The limited number of available variations of penetration, the lower studs being too low for present-day screen speed; the gaps between successive studs represent a change of 5 k.v. per stud. (2) The 5 ft. distance at which the radiograms are taken is a non-standard distance; a disadvantage in cardiac work. (3) The exposure factors are only sufficient to produce a lateral radiogram of the chest at a distance of 3 ft. in a patient of small build. (4) Patients cannot be X rayed in the erect position unless able to stand; many would be steadier and more comfortable in the sitting position. (5) The set cannot be used for stereoscopic work.

The manufacturers deserve credit for having produced so serviceable a plant, and no doubt in future models they will meet some at least of these difficulties. Many patients are able to sit up to be radiographed at a time when they are unable to stand. With more variations of penetration and smaller gaps between them it should become practicable to adjust penetration more exactly to the patient's thickness. It seems likely that the problem of obtaining penetrating views and lateral radiograms will be solved more easily when faster films or intensifying screens are available.

SMALL BOOKS ON GREAT MATTERS

THREE more of Cassell's "Health Handbooks," under the general editorship of Dr. A. D. Baker, have recently been published at 1s. each. The first, by Dr. G. J. V. Crosby, is concerned with "Insomnia and Disordered Sleep," the causes of which are classified as physical, psychical and mixed. Certain obvious extraneous causes such as noise or cold feet account for still another group. Among the physical causes the author rightly places high blood pressure; he calls this a disease of modern civilisation and large communities, whereas it is common enough among unhurried persons in rural areas. He also revives the boggy of auto-intoxication from a loaded bowel, an injudicious resurrection with which to confront an already purgative-ridden generation. Somewhat sweepingly he asserts that intoxication by the poisons of typhoid, acute fevers, syphilis, lead, and tobacco, if untreated, lead to hardening of the arteries. Though sound on the sleep requirements of children he perhaps exaggerates the significance of "the mysterious and frightening manifestations of puberty" which are surely nowadays for the most part properly dealt with. There is a short chapter on somnambulism and nightmares and appended to each chapter is a summary of conclusions.

In these days of infant welfare clinics the feeding and management of babies have been so thoroughly worked out that they are no longer very disputatious matters. "Healthy Babies," by the Hon. Mrs. Noel Olivier Richards, M.D., is a simple, authoritative, and practical little book with which it is difficult to find fault. Not everyone will endorse the view that weaning may be postponed till the twelfth month or even later. Prolonged suckling is undoubtedly a strain on some otherwise healthy women. The author advocates that when the baby is put to sleep out of doors it should lie in a secluded place free from interruption "by visitors

and out of reach of dustbins, brooms, drains, or kitchens or the dust from the road." Cats might have been added to the list. Dr. Richards takes the sensible view that masturbation in the young child should be ignored and that the tendency to examine and explore should not be discouraged. Perhaps, however, she over-emphasises the need to protect the small child from physical dangers. Any parent who has watched his or her offspring clambering upstairs or climbing into a high-chair will have been struck with the degree of native caution it displays if left to itself.

The third volume, entitled "Birth Control," is contributed by Dr. Helena Wright, and might well have been confined to practical matters, whereas it contains much propaganda in it. Some of the statements made seem over-dogmatic; for instance, that "there is no way of conducting a reasonable happy married life without a method of controlling the number of children," and again "the cap and chemical take about two minutes to place in position . . . and no harm results to the woman concerned if this technique is used every night for an indefinite number of years." On both of these points, picked at random from the book, it would seem impossible to make such a definite pronouncement at the present time. In her discussion of the problems of limiting the size of families Dr. Wright makes no mention or allowance for the rapid decline in natural fertility which is apparently occurring in the Western races. Although there will not be universal agreement among doctors that the best techniques have been here described, the book has undoubted merit. It is written in concise and simple style and its arguments and the descriptions of such methods of birth control as are advocated by the author are easy to follow.

A NEW FORM OF MERCURY ARC

THE mercury arc as we know it to-day has altered little since the early discoveries of Arons, Cooper Hewitt, Kuch, and others. The "atmospheric" type of burner made it unnecessary to tilt the tube, to strike the arc by applying external heat, but the mercury lamp still remained as a discharge between two massive pools of mercury. A new type of arc has recently been placed on the market by Messrs. Hanovia Ltd., which employs a new system of starting, though the final quality of output remains unchanged. This burner is based on the recent work of Spanner, and consists of a simple quartz tube containing a very little mercury, a certain amount of the rare gas argon, and is fitted with special electrodes of "activated" metal. When switched on, a spark discharge is established which rapidly heats up the electrodes until they are emitting electrons in the same way as the filament of a thermionic valve generates electrons. As the temperature rises the mercury is volatilised and the spark discharge passes into the normal mercury arc.

The new burner does not require tipping to start it and will burn in any position. It has other advantages over the standard type. Owing to the absence of the heavy reservoirs of mercury the tube is far less fragile and can be sent by post if well packed. The time taken for the establishment of full output is considerably less than with the standard type, probably because of the smaller quantity of heat needed. The new arc can run equally well on alternating and direct current, and since the alternating supply is becoming universal this is of great importance. The old form of three-electrode tube for A.C. never proved as satisfactory as the D.C. type.

As regards output a 15 per cent. increase is claimed on a reduced current. The quartz of the tube suffers the same progressive deterioration as has been observed in all other mercury arcs, but a new compensating rheostat has been incorporated by which the current can be pushed up after the burner has been in use for a certain number of hours.

It will be found that these advantages are reflected in the price, but the manufacturers are offering special terms for replacement of old burners.

THE GLAXO LABORATORIES

THE transfer, from cramped and adapted town premises to a spacious semi-rural site, of a manufacturing concern based on scientific control is a vast undertaking. The Glaxo company is to be congratulated on the successful way in which they have done this. A site of 15 acres at Greenford—that classic spot where Perkin discovered the first aniline dye—has given opportunity for considered and ordered design, an opportunity which has not been lost.

A long well-lighted very modern building with only one floor above ground level is arranged so that raw materials brought in at one bay, adapted for easy unloading of lorries, pass through the various processes in their way across the factory part of the building to a dispatch bay, without confusion or unnecessary handling: In some cases raw material is brought to the upper floor so that it may be ground, sieved, mixed with other products or otherwise treated; so the final preparation then gravitates to the lower level where it is divided into appropriate measured or weighed units and put in suitable containers for sale and use. All this necessary preparation is done with the minimum of effort and with proper regard to cleanliness, but without the eyewash of redundant precautions designed to make an impression on visitors.

The substances prepared at Greenford include vitamins A, B₁, B₂, C, and D, parathyroid extract, the oestrogenic hormone, ergot alkaloids, pituitary extract, and antiviruses and similar bodies; many of them are sent out in admixture with suitable food products or mineral constituents which may be deficient in the human body and form useful adjuncts to the organic preparations. Milk and malt products and cod-liver oil of guaranteed potency are also handled at Greenford. Most of the products mentioned can only be offered with confidence to medical men and their patients if their activity and composition can be guaranteed as suitable and reasonably constant in batches made or sold at different times. The greater part of the upper floor of the Greenford laboratories is therefore devoted to control and research.

The chemical laboratory consists of one large room where research and analytical control goes on side by side. This arrangement which, although not usual, is followed in some other large laboratories, such as those at County Hall, has the advantage of enabling the scientific staff to survey the whole of the work and ensures the pooling of knowledge, experience, and initiative, besides easing the dislocation caused by sickness or holidays. Chemical control is supplemented by physical examination where this is of service, as, for example, in the spectrometric assay of vitamin A.

Chemical or physical examination suffices for some purposes and in others enables batches of material to be packed ready for issue, but where the question of activity is important, as in the case of vitamins, actual issue is delayed until experiments on animals have shown that the preparation is up to standard. For this purpose a large animal department is kept up, in which thousands of white rats of the well-known Wistar strain are bred and stored, both for sale to research workers and for experiments in the laboratory itself. Besides the laboratories mentioned others are devoted to bacteriology and the preparation of vaccines.

The occupation of the new laboratories was carried out very carefully; an illustrated pamphlet was distributed among the workers before the move was effected, and everyone could see from it where he would be working and how to get there, besides finding his way to any part of the building which might concern him. When a visit was paid to Greenford, a

few weeks after the move, everyone seemed as "native and to the manner born"; the obvious newness of the building and some plant erection which was going on were the only signs that the place had not been running smoothly for years.

SPECIMENS IN THE POST

FEW parcels can be more unpleasant, if not dangerous, in the post than material badly packed and sent for pathological examination. To prevent the risk of infecting Post Office servants and of contaminating the mails, the Postmaster-General has drawn attention—he says he has reason for doing so—to the conditions for sending specimens. The material must be in a hermetically sealed or securely closed container, placed in a strong case with enough absorbent packing to prevent movement and any possible leakage. It must be clearly labelled "Pathological specimen. Fragile, with care," and sent only by letter post. If a packet fails to conform to these regulations it is at once destroyed with all its wrappings and enclosures, and the sender is liable to prosecution.

A DISCLAIMER

Drs. David and Robert Thomson write to disclaim responsibility for the publicity given to an article which they and Mr. E. T. Thompson recently wrote on giving vaccine by mouth. "The lay press's interest in colds and influenza," they say, "is so great that it is almost dangerous now for a doctor to publish an article on the subject except in some obscure medical journal."

Vacancies

For further information refer to the advertisement columns

All Saints' Hospital, Austral-street, West-square, S.E.—Res. H.S. At rate of £100.

Archway Hospital, Archway-road, N.—Asst. M.O. £250.

Barnby, Caernarvonshire and Anglesey Infirmary.—Sen. and Jun. H.S.'s. At rate of £150 and £100 respectively.

Bath and Wessex Children's Orthopaedic Hospital, Combe Park.—H.S. At rate of £120.

Birmingham, Queen's Hospital.—Sen. Res. Anæsthetist. At rate of £70-£100.

Birmingham, Romsley Hill Sanatorium.—Res. Asst. M.O. At rate of £240.

Birmingham, St. Chad's Hospital.—Jun. Res. M.O. At rate of £150.

Blackburn, Queen's Park Hospital and Institution.—Res. Jun. Asst. M.O. At rate of £150.

Bolton Royal Infirmary.—Res. Surg. O. £250.

Bradford, Municipal General Hospital, St. Luke's.—H.P.'s and H.S.'s. Each at rate of £150.

Brighton, Royal Sussex County Hospital.—Second Asst. Pathologist. £450.

British Postgraduate Medical School, Ducane-road, W.—Two First Assts. for Dept. of Surgery. Each £250-£500.

Cambridge, Adlenbrooke's Hospital.—H.S. At rate of £130.

Cancer Hospital, Fulham-road, S.W.—Res. M.O. for Radium Dept. At rate of £100.

Carlisle, Cumberland Infirmary.—Second H.S. At rate of £155.

Central London Ophthalmic Hospital, Judd-street, W.C.—Sen. and Jun. H.S. £120 and £100 respectively.

Chelsea Hospital for Women, Arthur-street, S.W.—Registrar (Gynecological) and Radium Officer. £75.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Asst. Laryngologist.

Constance-road Institution, East Dulwich, S.E.—Asst. M.O. £250.

Coventry and Warwickshire Hospital.—Res. Cas. O. £125.

Eastbourne, Princess Alice Memorial Hospital.—Hon. Anæsthetist.

Egyptian Government.—Director of Lunacy Division in P.H. Dept. L.E. 1020 to L.E. 1200.

Evelina Hospital for Sick Children, Southwark, S.E.—H.P. At rate of £120.

Forest Gate Hospital, Forest-lane, E.—First Asst. Res. M.O. £525. Also Second Asst. Res. M.O. £350.

Gloucestershire Royal Infirmary, &c.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.

Halifax Royal Infirmary.—Third H.S. At rate of £150.

Hampstead General and N.W. London Hospital, Haverstock Hill, N.W.—Cas. Surg. O. for Out-patient Dept. At rate of £100.

Hertford, Ware Park Sanatorium.—Asst. M.O. £300.

Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W.—Surg. Reg. £100. Also Clin. Asst. to Ear, Nose, and Throat Dept.

Hull Royal Infirmary.—First H.S. £150.

Ilford, West Ham Mental Hospital, Goodmayes.—Jun. Asst. M.O. £350.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. £144.

Ipswich Mental Hospital.—H.P. £150.

Kingston upon Hull City and County.—Asst. M.O.H. £600.

Leicester County Sanatorium and Isolation Hospital, Markfield.—Jun. Res. M.O. At rate of £300.

Lewisham Hospital, High-street, S.E.—Asst. M.O. £350. Also Asst. M.O. £250.

Lincoln County Hospital.—Jun. H.S. At rate of £150.

Liverpool, Bootle General Hospital.—H.P. and H.S. Each at rate of £150.

London Fever Hospital, Liverpool-road, N.—Anæsthetist.

Manchester, Booth Hall Hospital.—Jun. Asst. M.O. At rate of £200.

Manchester, Duchess of York Hospital.—Sen. Res. M.O. At rate of £125.

Manchester Royal Children's Hospital, Gartside-street.—Two Asst. M.O.'s for Out-patients' Dept. Each at rate of £150.

Manor House Hospital, Golders Green, N.W.—Jun. M.O. £200.

Metropolitan Hospital, E.—Hon. Surgeon. Also Surg. Reg.

Middlesex County Council.—Tuber. M.O. £750. Tuberculosis Sanatorium, South Mimms. Deputy Med. Supt., &c. £450.

Middlesex Hospital, W.—Anæsthetist. Also Asst. Anæsthetist. £100.

Miller General Hospital, Greenwich-road, S.E.—Cas. O., Out-patient Officer. Each at rate of £150. Also H.P. & H.S. Each at rate of £100.

Mount Vernon Hospital, Northwood.—H.S. At rate of £150.

National Hospital, Queen-square, W.C.—Res. M.O. £200.

Nelson Hospital, Merton, S.W.—Two Res. H.S.'s. Each at rate of £100.

New End Hospital, Hampstead, N.W.—Asst. M.O. £250.

Nottingham General Hospital.—H.S. for Fracture and Orthopaedic Depts. £300. Also H.S. to Ear, Nose, and Throat Dept. At rate of £150.

Plymouth, Prince of Wales's Hospital, Greenbank-road.—H.S. and H.P. Each at rate of £120.

Preston, Biddulph Grange Orthopaedic Hospital.—Jun. H.S. At rate of £200.

Prince of Wales's General Hospital, N.—Res. Jun. H.P.'s and H.S.'s. Each at rate of £90. Also Hon. Med. and Surg. Regs. Each £100.

Princess Beatrice Hospital, Richmond-road, Earl's Court, S.W.—H.S. and H.P. Each at rate of £110.

Queen's Hospital for Children, Hackney-road, E.—H.P. and Cas. O. Each at rate of £100.

Rochdale Infirmary and Dispensary.—Second H.S. £150.

Royal London Ophthalmic Hospital, City-road, E.C.—Sen. Res. O. £150.

Royal Naval Medical Service.—Eight vacancies.

St. Andrew's Hospital, Devons-road, E.—Asst. M.O. £250.

St. Bartholomew's Hospital Medical College.—Sen. Demonstrator in Dept. of Pathology. £400.

St. George's Hospital, S.W.—Asst. Bacteriologist. £500.

St. Leonard's Hospital, Hoxton-street, N.—Asst. M.O. £250.

St. Luke's Hospital, Sydenham-street, S.W.—Asst. M.O. £250.

Salisbury Royal Hospital.—Hon. Asst. Gynecologist.

Salisbury General Infirmary.—H.S. At rate of £125.

Southampton, Isolation Hospital and Sanatorium.—Jun. Res. M.O. £200.

South Eastern Hospital for Children, Sydenham, S.E.—Jun. Res. M.O. At rate of £100.

South London Hospital for Women, Clapham Common, S.W.—H.P. At rate of £100.

Stoke-on-Trent, North Staffordshire Infirmary.—Radium Officer. £500.

Swansea County Borough.—Asst. M.O. £500.

Tancred's Studentships.—Three. Each £100.

University College Hospital, Gower-street, W.C.—Bilston Pollard Fellowship. £650.

Warrington County Mental Hospital, Winwick.—Asst. M.O. £500.

Warwickshire County Council.—Asst. County M.O.H. £500.

Westminster Hospital, Broad Sanctuary, S.W.—Obstet. Tutor and Reg. £100.

West Riding of Yorkshire, Middleton-in-Wharfedale Sanatorium.—Res. Asst. M.O. £350.

Whitechapel Venereal Diseases Clinic, Turner-street, E.—Director. £1250.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Rhondda (Porth) (Glamorgan), Cowbridge (Glamorgan), and Larkhall (Lanark).

ROYAL HALIFAX INFIRMARY.—Increased funds are needed at this hospital if the standard of efficiency is to be maintained. During the year 22,372 patients were treated, an increase of 1603 on the previous year, and the average cost of each in-patient was £6 8s. 4d. Workpeoples' contributions for the first time exceeded £10,000, and the paying patients' ward produced £4750.

INDEX TO "THE LANCET," Vol. II., 1935

THE Index and Title-page to Vol. II., 1935, which was completed with the issue of Dec. 28th, is now ready. A copy will be sent gratis to subscribers on receipt of a post card addressed to the Manager of THE LANCET, 7, Adam-street, Adelphi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

ADDRESSES AND ORIGINAL ARTICLES

JOHN HUNTER TO JOHN HILTON*

BY C. H. FAGGE, M.S. Lond., F.R.C.S. Eng.,
F.R.A.C.S. (Hon.)

CONSULTING SURGEON TO GUY'S HOSPITAL, LONDON

"It would be well, I think, if the surgeon would fix upon his memory as the first professional thought which should accompany him in the course of his daily occupation this physiological truth—that Nature has a constant tendency to repair the injuries to which her structures may have been subjected, whether those injuries be the result of fatigue or exhaustion, of inflammation or accident."—JOHN HILTON—"Rest and Pain."

In any attempt to assess a teacher's claim to greatness we must consider the influence he exerts upon his pupils.

In his Hunterian oration of 1921, Sir Charters Symonds¹ traced the influence of Hunter upon the surgery of the succeeding generation in the person of Sir Astley Cooper; it will be my endeavour to link up the teaching of John Hunter with that of John Hilton—with one of a generation later than that of Astley Cooper. The Hunterian lesson did not come direct to John Hilton—Hunter had been in his grave more than thirty years when Hilton went to Guy's. But Cline of St. Thomas's was one of his most ardent disciples and Astley Cooper of Guy's was himself a pupil of Hunter, and further, worked under Cline from whom, as Sir Charters Symonds has told us, he derived the spirit which Hunter inculcated.

It is no disadvantage to my purpose that Astley Cooper and John Hilton were in many respects dissimilar. Astley Cooper was a man of fine presence, courtly manners, and an operator of enterprise and dexterity. When we attempt to conjure up his personality we cannot escape from the influence of Lawrence's portrait which hangs in our council chamber and in which the silk knee-breeches and swallow-tailed coat proclaim the aristocrat of mind as well as of bodily form. Hilton was broad, short, and brusque in manner. In appearance he suggested a successful man of business in the city rather than a scientific surgeon: he wore the heavily braided

broadcloth of early Victorian days, with a flowered waistcoat and widely open collar. Hilton had no chance to become an assured operator, but as a scientific investigator and thinker he was much more closely in accord with Hunter's traditions than his illustrious predecessor. I venture to think that Hilton more fully understood their significance, and pursued his inquiries in a scientific spirit which Astley Cooper had not at his command.

John Hilton, the eldest son of John and Hannah Hilton, was born in 1805 at Sible Hedingham in the county of Essex, and was educated at the grammar school (now known as King Edward VI.'s School), Chelmsford, and at Boulogne. During his boyhood his parents were in poor circumstances; in later years his father's interest in the straw-plaiting industry prospered, but at the time John Hilton

went to Guy's in 1824 he could not afford to purchase an apprenticeship to a member of the staff, so that, when twenty years later he was elected assistant surgeon, he was the first member of the surgical staff of any London hospital whose appointment had not been "bought and paid for."

During his studentship Guy's medical school separated from that of St. Thomas's and Hilton, appointed in 1828, was the second demonstrator of anatomy in the new medical school: he taught in the dissecting-room for sixteen years and gained the nickname of "Anatomical John."

Hilton was a member of the surgical staff of Guy's from 1844-70. In 1843 he was one of the 300 original fellows of this College to be elected under the terms of our third Royal Charter; he was vice-president from 1865-67, and was elected president in 1867, serving for one year only as was customary in those days. He died of cancer of the stomach at

Hedingham House, Clapham Common, on Sept. 14th, 1878.

In his obituary notice of Hilton, Mr. Jacobson has little to tell us of his youth and upbringing.² Mr. Jacobson's essay is, in my judgment, the equal of his better known essay on Arthur Durham³; this latter was obviously a labour of love and showed Jacobson at his very best. His ease of diction, the purity and simplicity of his prose, and his unerring aptitude of quotation gained for the writer a place which no

John Hilton

* Part of the Hunterian oration for 1936 delivered before the president and council of the Royal College of Surgeons of England on Feb. 14th.

³ Jacobson, W. H. A.: Ibid., 1895, lii., 43.

other of my teachers at Guy's at the end of the last century could contest.

In the former essay Jacobson argues that success in life without the help of a good education, money, or influential friends stamps a man as above the common, and quotes Hilton as an example. What little he tells us of Hilton's student days includes the story of a dinner which after the separation of Guy's from St. Thomas's in 1826 was held annually and which was the origin of the United Hospitals Club, a dining-club which still flourishes after celebrating its centenary in 1928. To this dinner in one of his later student years Hilton was bidden. The habits of those days were unchecked by the conventions of to-day, and as chair after chair became vacant, either by the guest leaving, or finding repose under, the table, Hilton moved up until he reached a seat of honour at one side of the chairman, Benjamin Travers.

Contemporary events must have had a great influence upon the mind and career of John Hilton. His childhood was, without doubt, darkened by the spectre of the "Corsican Ogre" who dominated Europe until the year 1815 saw his overthrow. Those whose youth has been spent in the shadow of the Great War and the hardships of the succeeding years will have sympathy for Hilton whose own boyhood, rather more than a century earlier, must have been deprived of the few luxuries which might have been possible had not England been in the trough of a world-wide trade depression.

Another event which must have had a most important effect upon his career was the Anatomy Act of 1832. A previous Bill to amend the law relating to the supply of bodies for dissection had been opposed in 1829 by a petition from the president and council of this College, who considered it "injurious to the interests and advancement of the profession of Surgery and to the Rights of your Petitioners." Largely owing to the activity of Sir Astley Cooper the amended Bill, which became law in 1832, was altered to comply with the views of the College. William Hunter had been the first British anatomist to provide opportunities for individual dissection by students, when he founded his school in 1746,⁴ this innovation, it has been said, was the greatest debt—and that of many—which surgery owes to William Hunter. But in spite of this, anatomical knowledge made little progress largely owing to the precarious supply of material.

In the same year as Hilton was appointed demonstrator of anatomy, the action of Bransby Cooper *v.* Wakley took place. Hilton's part in this can only have been a passive one yet, this group of Guy's surgeons shows that even at that date he had acquired some repute as an anatomist.

It is difficult to believe that only a hundred years separate us from the time when such errors in taste as are here depicted and what would now be regarded as contempt of court were permissible, yet there is no reason to suppose that our manners and conventions will appear any more acceptable to the educated classes of a century hence than are those of a hundred years ago to us. When we consider the increased rapidity of travel, and the easy interchange of thought and experience which the scientific discoveries of the past century have rendered possible, it is interesting to reflect that at Waterloo in 1815 the rival armies moved at no greater speed than

could prehistoric warriors who had subjected the wild horse to domestic use; there had till that date been no speeding-up in communications between different parts of the world.

In 1825 George Stephenson's steam-engine was first used for passenger and goods traffic on the Stockton-Darlington line. We have perhaps as yet scarcely realised the influence of the ever-increasing rapidity of communication of modern times upon the fortunes of the British Empire, and it is doubtful whether those who were witnesses of early steam locomotion could visualise the effect it would produce upon nations and upon the progress of knowledge throughout the world.

John Hilton as an Anatomist

One of Hilton's chief claims to the approbation of posterity is the dissections which he made in order that Joseph Towne should copy them in wax. Towne's wax models, which include the most beautiful and best known anatomical models in the world, also depict many varieties of skin disease and certain morbid processes. They are nearly one thousand in number and most of them adorn the museum of Guy's Hospital; it is remarkable that the colour and consistency of the wax still remain unchanged after a lapse of over one hundred years.

Joseph Towne,⁵ the son of a dissenting minister at Royston, came to London by coach to obtain the opinion of an anatomical authority upon the accuracy of a wax model of a human skeleton which he had fashioned secretly at night. It is stated that he had never seen a complete human skeleton. Knowing no one in London he knocked by chance at the house of a doctor in Hackney who gave him an introduction to Sir Astley Cooper; in the year 1826, at the age of 17, he became modeller to Guy's, two years before Hilton began to teach anatomy. His appointment, so far as I can discover, was made by Benjamin Harrison, on his own responsibility, for the minutes of the governors' committee contain no record of Towne's election. Benjamin Harrison—whose despotism gained for him the name of "King" Harrison—was the Guy's treasurer whose strong hand and sound judgment of men guided so wisely in its early years the fledgling⁶ which had just left the parent nest. Towne was a great artist, even though he was entirely self-taught. His model in wax of a skeleton gained the first silver medal of the Society of Arts, and is now in the Guy's Hospital museum. He was awarded the gold medal of the Society of Arts in 1827 for a model in coloured wax of the human brain, one of a series which is "read up" by all Guy's students. Towne served Guy's for over 50 years—in fact, probably till the date of his death in 1879. He worked alone in a locked room and the secret of his methods died with him.

Hilton was a pioneer in the accurate and detailed description of topographical anatomy, of which he was one of the first to show the value to any young man who aimed at distinction as a surgeon. It is well for this College to bear this in mind as there are those who, never having had any degree of insight into this subject, question its practical application to surgery. In Hilton's day the modern textbook of descriptive anatomy did not exist; such books as there were for the medical student in 1824⁷ contained a smattering of superficial anatomy,

⁴ Bryant, T.: Guy's Hosp. Rep., 1883, xii., 1.

⁵ Guy's separated from St. Thomas's in 1826 in part; the final separation took place in 1849.

⁷ Bell, John: The Anatomy of the Human Body, 1803.

⁶ William Hunter took over Sharpe's School and lectureship in 1746, and established his own school in Great Windmill-street in 1770.

strongly interlarded with physiology of an elementary type, and any observations on comparative anatomy as seemed to be even remotely relevant to the structure which was being described.

In the year 1839 Hilton was made a Fellow of the Royal Society, chiefly for his work on the superior

Wax model of skeleton made by Joseph Towne.

laryngeal nerve of man; from his dissections of this and other nerves in man he evolved Hilton's law—which states that a nerve supplying the muscles which control the movement of a part also supplies the skin or other sensory surface which overlies that part. In later work he elaborated this theory in a most important relation when he showed that the nerves, supplying the muscles controlling a joint and sensation to the skin over the joint also supply the structure of the joint itself. He writes: "The same trunks of nerves, whose branches supply the groups of muscles moving a joint, furnish also a distribution

of nerves to the skin over the insertions of the same muscles; and the interior of the joint receives its nerves from the same source."

Hilton does not appear to have thought of pursuing this idea or to have been alive to the obvious deductions arising out of this discovery—for it is not until 1876 that Ferrier's work on monkeys established the presence of cortical centres. This led ultimately to the conception that the association of motor and sensory tracts could be carried much further back to the cerebral cortex where it has been shown that the centres for associated functions are in close anatomical relationship.

Hilton's work "On the Cranium" is less well known than his other anatomical writings, but in some ways it is even more worthy of notice. Part of this book, which is founded on his anatomy lectures delivered at Guy's, appeared in the *Guy's Hospital Reports* just before their temporary demise in 1853.⁸ This interruption was the reason for their separate publication.

Its opening paragraphs disclose the foundation of his anatomical beliefs—the dependence of structure upon function or, as Hilton himself puts it, "Nature's universal precision in adapting means to ends." The capacity of the author to extract points of interest, even from dry bones, is apparent in every line—thus the frontal sinuses act as a natural protection to the brain in adults which is absent in children. The superciliary ridges, with the eyebrows,

serve the purpose of diverting the "sweat of the brow" of the working man from passing over the eyeball when it would obstruct his vision. Frequent attention is drawn to physical signs of surgical importance—e.g., the meaning of a depressed or raised anterior fontanelle in a baby. To our generation Hilton's unceasing endeavour to explain the form and position of every structure by its alleged function is somewhat tiresome, but allowance must be made for his teleological views.

He disposes of phrenology by pointing out the dissimilarity between the exterior of the skull and the surface of the brain, and makes observations upon the function of the cerebro-spinal fluid, though it will be noticed that he had no conception of its purpose save as a purely mechanical buffer for the brain or as a substance which could replace, or be replaced by, an equivalent volume of blood. To establish this belief he performed a series of experiments on the cadaver and showed that when he forced blood into the cranial cavity there was "an afflux of cerebro-spinal fluid into the spinal canal."

He is in doubt whether the clear fluid which escapes from the ear of a boy with a fractured base is cerebro-spinal fluid, so he compresses the jugular veins to promote intracranial congestion, and is convinced that the increased flow of fluid from the ear is conclusive evidence that it is cerebro-spinal fluid.

He is much interested in the various ridges of compact bone which pass in all directions along and across the base of the skull; he attributes to them the function of transmitting vibrations from falls on the vertex or those carried upwards from the spine, and devises an experiment which confirms his view that the petrous portion of the temporal bone plays a very important part in collecting these vibrations and diverting them from any deleterious influence which they might exert upon the brain. Hilton's teaching inculcates the value of observation; for on a visit to Gloucester Cathedral he finds "similarity in a portion of its structure to the position of the vomer in the nasal cavities."

From 1845 to 1853 Hilton lectured every weekday at 2 P.M.; in the same year as he began to lecture on anatomy Dr. Gull was appointed the first lecturer on physiology in the Guy's medical school. Hilton's interest in topographical anatomy is evidenced by his teaching in the dissecting-room, and by the actual dissections which he prepared for Towne, but in addition the scientific aspect of anatomy attracted him. So his lectures, like those of all his contemporary anatomists, lean markedly towards teleology, which, strengthened by the recent publication of the Bridgewater treatises, reigned supreme in the London schools of his day.

John Hilton as a Surgeon

The sudden death of Aston Key, senior surgeon to Guy's Hospital, of cholera, in 1849, made John Hilton a full surgeon at the age of 44—in current parlance "gave him his beds," for in those days the assistant surgeons at Guy's had charge of out-patients only.

At that time Lister had not yet given his message of hope to suffering humanity. Primary union rarely occurred—a ligature was left long with its ends hanging out of the wound; dry lint and strapping were the first dressing. Moreover, anaesthesia was in its infancy, for the use of chloroform as an anaesthetic by inhalation had been advocated by James Simpson only two years previously.

⁸ A new series began in 1855.

Hilton held the post of surgeon to Guy's until 1870, there being no age limit at that date.⁹ He gained the reputation of being a cautious scientific surgeon—not prone to any operation which did not promise well for his patient. It is unlikely that he acquired any degree of dexterity or brilliance, for, as has been noted, he had no operative experience as a young man—the smaller hospitals which now abound in and around our large cities and which provide welcome nurseries for the young surgeon of to-day being at that date unheard of. Nevertheless, his attitude towards surgery is demonstrated by his ability to introduce a new method for opening a deeply seated abscess; in his own words, “cut with a lancet through the skin and cellular tissue and fascia . . . then push a grooved director . . . into the swelling.” “A blunt instrument such as a pair of dressing forceps is then run along the groove in the director into the swelling, when by separating the handles you may ‘so tear open the abscess.’”

He is of opinion that such a “lacerated track” will not close prematurely. This is still known as Hilton's method.

In Jacobson's opinion² his imperishable claim to be remembered as a great scientific surgeon rests on the sound blending of anatomy and physiology in his teaching. For it was as a clinical teacher that John Hilton made his surgical reputation; he brought to this task the same spirit of inquiry as had characterised his earlier scientific work. “However chronic and uninteresting, however trite and trifling seemed the case, he had the power of getting information out of it.” He was constantly inquiring the reason for symptoms and signs, and allotting to each a significance which did not appear obvious to others, yet, when mentioned by the master, seemed to be peculiarly apt.

“Rest and Pain”

In the years 1860 to 1862 Hilton was professor of anatomy and surgery to the Royal College of Surgeons; in this capacity, known after 1868 as Arris and Gale lecturer, he delivered annually six lectures, which, in book form, became his classic¹⁰—familiarily known as “Rest and Pain.”

Hilton's classification of Rest as Mechanical and Physiological, clearly defines two distinct and separate conditions not necessarily of similar aim or of equal value. Physiological rest does not imply immobility; for instance, the heart or stomach obviously cannot be brought to rest, yet rest for both these organs may be attained by the acquisition of a state of eased function favourable to recuperation and repair. He points out that repair can only occur satisfactorily when the part affected is in complete repose and that pain is the common danger signal that rest is necessary.

In these days of scientific instruments of precision, the practitioner of medicine is apt to fail to attach due importance to those features of a sick patient which are open to his own observation. Yet Hilton's dictum that every pain has its distinct and pregnant significance if we will but carefully search for it, still remains “the whole truth,” and every medical man, however small his experience, must realise that pain is, above all other symptoms, the one for the

relief of which a doctor is consulted. Therefore, it is scarcely possible to overrate the clinical value of pain. Keith¹¹ writes: “If Hilton's first service to surgery was to give ‘rest’ a foremost place in the means of treatment, his second was to give ‘pain’ its rightful place in the means of diagnosis.”

Hilton's teaching showed the way in which the clinical value of pain may be assessed—i.e., by careful and precise observation. He draws a tragic picture of our first parent ejected from the Garden of Eden, confronted by “his first wound, his first experience of pain,” with the recent denunciation “Thou shalt surely die” still ringing in his ears. He shows that all life needs periods of rest, and quoting John Hunter as an authority on this matter in relation to plants, asks, “What would have been the condition of man on earth had it pleased the Creator to withhold from him this power of repairing his injured tissues?”

He emphasises the value of sleep as a therapeutic agent, especially for children. One of Hilton's most valuable clinical observations was in relation to the fixation in flexion of an inflamed joint. To quote his own words: “When the interior of the joint is in a state of inflammation or of irritation, the influence of this condition is carried to the spinal marrow, and thence reflected to the various muscles of the joint, through the medium of the associated motor nerves, the muscles being supplied by the same nerves that supply the interior of the joint.” A fixed joint is thus produced and this fixation is only relaxed under anaesthesia. He writes further: “the flexors by virtue of their superior strength, compel the limb to obey them, and so force the joint into its flexed condition”—the joint thus becomes rigid and flexed.

Here Hilton made a pathological observation of considerable physiological importance; his was a forecast or original thought upon a subject which was as yet imperfectly or only partly understood. It is true that in 1833 Marshall Hall¹² had described “excito-motor” (reflex) actions, but his hypothesis embraced only the muscular response to the excitation of a sensory surface. To Hilton must be attributed the originality of the conception that abnormal stimuli from a joint—the seat of injury or disease—can influence the position of the limb through the action of muscles which owe their innervation to the same nerve trunks as those which supply the joint.

Again, in the same paragraph he notes that the skin over an inflamed joint is very sensitive; thus he describes the condition which we now know as cutaneous hyperaesthesia and considers it to be a result of the distribution of the same nerves to the joint and to the skin over it. He shows that the distribution of the auriculo-temporal nerve leads to the association of earache and toothache with unilateral furring of the tongue—a “functional and structural deterioration depending upon nerve influence.”

As was only to be expected Hilton's explanations or conclusions in relation to the causation of many affections have not stood the test of time. It is more amazing that much of what he wrote still seems true, and that his foresight in regard to function was so accurate. His trend is always to supply a mechanical reason for a physiological or pathological process. This is only natural in the latter case as he

⁹ The minutes of the general court of governors of Guy's Hospital show that the regulation making 60 the age limit of the members of the staff was passed in 1853. This would, of course, not apply to those members of the staff elected before that date.

¹¹ Keith, Sir A.: *Memoirs of the Maimed*. London, 1919, vol. x., p. 29.

¹² Hall, M.: *On the Reflex Function of the Medulla Oblongata and Medulla Spinalis*, 1833.

did not foresee the rôle of bacteria in the causation of disease; for instance, he answers the question, "Why does a surgeon open an abscess" by the statement "To give its internal surfaces rest," and insists that such an opening must be situated "at its lowest part."

He was much interested in the case of John Carter, a man of 21, who had fallen from a tree when in the pursuit of young rooks. He had sustained a "crush fracture" of the bodies of the fifth, sixth, and seventh cervical vertebræ and a complete transverse lesion

of the spinal cord at the same level, with the result that he had total loss of power and sensation in his legs, trunk, and arms. He lived for fourteen years after the accident and earned his livelihood by drawing with a pencil or pen held between his teeth. A reviewer in the *British Medical Journal* of 1863 wrote of "Rest and Pain": "that Mr. Hilton's lectures are perhaps the most considerable contribution to surgical literature furnished by any of the professors of surgery who have occupied the Chair of the College of Surgeons since Sir James Paget's celebrated lectures on 'Inflammation' in 1850." It is open to question whether Hilton's lectures

A vertical section of John Carter's spine.

have not had the more lasting influence on surgical progress. In regard to style, Hilton has no superior among medical writers: his characteristics are the simplicity, purity, and vividness of his English.

Sir Arthur Keith's opinion of the work of Hilton is shown in his book "Menders of the Maimed," of which the first chapter is devoted to John Hunter and the second to John Hilton. He shows how the practice of Hilton's principle of rest has helped humanity. Surgeons are slow to learn lessons. In the late war one of the commonest causes of death after gunshot fracture of the thigh bone was shock. It was not at first realised that this was due to defective immobilisation during transport, yet this factor disappeared or at least dwindled into insignificance so soon as the Thomas's knee splint—itsself an apparatus well known for many years—was restored to favour. Here was merely an illustration of the old lesson which Hilton taught.

His deductions from his physiological experiments on pain led him to advocate certain lines of treatment. Such a sequence of thought should be the scientific basis of all therapeutic measures.

John Hilton and Modern Surgery

John Hilton's thesis that the surgeon should rely on nature's ability to secure healing of many lesions provided that the injured part has been put under the favourable conditions of absolute physiological rest is necessarily followed by the corollary that the surgeon should be satisfied with the minimum of active interference:

Hilton did not and could not be expected to foresee the impetus to surgery which Lister's work has

afforded—shortly to be multiplied a thousandfold by the advent of aseptic surgery which was a logical outcome of Listerism.

Modern surgery has not abandoned the principle of physiological rest—rather has it recognised its value and has increased the number and complexity of the procedures by which that state may be attained. It would be instructive to discover how far those who were responsible for the introduction of the various short-circuiting operations—such as gastro-jejunosotomy, that for the production of a pneumothorax, or the fixation of a limb in plaster for the resting of paralysed muscles—appreciate that they were merely following the principle laid down by Hilton when he insisted on the therapeutic value of physiological rest.

Reference has already been made to the value of anatomy in surgery, and while operative dexterity depends upon anatomical exactitude in most operations rendered possible by recent advances, it must be admitted that the dissecting-room is no longer as it was in Hilton's day the sole or in fact the most important path to surgery. A comprehensive knowledge of physiology, not only in theory, but also by experimental methods, has become essential to the surgery of progress. It is perhaps strange that Hilton should have gained the reputation of being the best anatomist in London, whereas if John Hunter must be regarded as the first British physiological surgeon, Hilton has supreme claims to be ranked as his immediate successor.

John Hilton as Hunterian Orator

In the year 1867 John Hilton delivered the Hunterian oration; he was at that time the senior vice-president of this College.

In his oration Hilton postulates that Hunter's trustees—Matthew Baillie and Everard Home—in establishing the oration, had a much higher object in view than the mere laudation of Hunter . . . "their main object," he writes, "was to perpetuate in our profession the mind that was in Hunter . . . to inspire Hunter's successors with the same ardour of professional pursuit." He goes on to inquire what "manner of mind" Hunter was possessed of, and is of opinion that its essential and outstanding attributes were its industry, inquisitiveness, and common sense.

Hilton emphasises an aspect of Hunter's position which does not appear to have been given its due weight, and that is "the solitariness of his pursuits—the want of a single mind to sympathise with his large and exalted view of the grandeur of animate nature—which must have had a chilling influence on his enthusiastic temperament. We shall fail to appreciate the full measure of Hunter's mental stature if we do not recognise the difficulties under which he toiled."

Hilton's Hunterian oration deals chiefly with sympathy—which would, in modern scientific language be termed referred pain—and gives as an example the pain at the end of the urethra occasioned by a stone in the bladder; he contrasts the theories of Darwin and Hunter in explanation of such phenomena and attempts to prove that they harmonise with his own work on the physiology of pain. He points out that Hunter had observed that in affections of the hip or the loins, "the sympathising pain is felt in the knee before it is felt in the original seat; he shows that accurate knowledge of the distribution of the obturator, anterior crural and sciatic

nerves to the hip and knee joints sufficiently explains what Hunter was driven to veil under the covering of sympathy." He passes on to make several original observations upon the reflex sympathies of which the 5th cranial nerve provides the afferent and efferent paths, and remarks in explanation of Hunter's observation that in diseases of the liver pain is referred to the right shoulder—"the shoulder sympathises with the liver but the liver never sympathises with the shoulder." He explains this sympathy on the assumption that the right phrenic arising from the 3rd and 4th cervical nerves (which also supply the skin over the point of the shoulder) gives off a branch into the porta of the liver.

Hilton further reminds us that nature has a remarkable power of recuperation; if we do not prevent her she can bring about the patient's recovery; at times it may be that she needs our aid, and when this is so he endeavours to point out the lines upon which this assistance should be based. This is, after all, only what Hunter taught. Keith¹¹ writes: "Were I to cite the most important contribution Hunter ever made to surgery, it would be his clear recognition of the fact that restoration is effected by powers inherent in the living tissues of the patient; the surgeon can only help recovery by tending these powers."

Hilton had advanced in outlook and breadth of knowledge in the years between his "Rest and Pain" and his Hunterian oration, yet apparently he does not dream of bacterial activity in disease when he accepts the Hunterian idea of sympathy as a large factor in the causation of tetanic spasms, although he admits that the pathology of this disease "is still indefinite."

When Hilton thought and wrote about matters of supreme importance he showed a disbelief in Darwinian evolution. His views may be gathered from a sentence in his oration¹³ before the members of the Hunterian Society. "When we approach the consideration of life itself or the spirit we are restrained by our finite reason. All is darkness to the human understanding." "... These are mysteries ... as inscrutable alike to the sage and to the savage ... they are left in doubt purposely to make us set a right value upon all human science."

Here is the faith of this successor to Hunter, whose work for surgery and influence upon surgical thought have seemed worthy of our remembrance upon a day dedicated to the homage of his master.

¹¹ Lond. Med. Gaz., 1844, xxxiii., 673.

HOSPITAL COÖRDINATION IN LANCASHIRE.—The Lancashire public assistance committee has appointed a special subcommittee to consider whether the control of public assistance hospitals should pass from the committee and be given to the county council public health and housing committee.

Dr. F. de B. Pim, whose death was announced at the end of January, retired from practice in the Barrowford and Nelson districts some two years ago. He was prominently associated with the St. John Ambulance movement and was a Knight of Grace of the Order of St. John. For over 50 years he worked for the Ambulance Association becoming the foremost figure in the district, and to commemorate his 50 years' service a presentation of money and plate was made to him. One cup he gave to be held as a challenge cup between ambulance centres of Lancashire, and another for competition among police ambulance centres.

EXPULSIVE FORCE OF THE UTERUS DURING LABOUR*

By CHASSAR MOIR, M.D., F.R.C.S. Edin., F.C.O.G.
READER IN OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF LONDON

"My father, who dipped into all kinds of books . . . had found out, that the lax and pliable state of a child's head in parturition, the bones of the cranium having no sutures at that time, was such,—that by force of the woman's efforts, which, in strong labour-pains, was equal upon an average, to the weight of 470 pounds avoirdupois acting perpendicularly upon it,—it so happened, that in 49 instances out of 50, the said head was compressed and moulded into the shape of an oblong conical piece of dough, such as a pastry-cook generally rolls up in order to make a pie of.—Good God! cried my father, what havoc and destruction must this make in the infinitely fine and tender texture of the cerebellum! . . . But how great was his apprehension, when he further understood, that this force acting upon the very vertex of the head, not only injured the brain itself, or cerebrum,—but that it necessarily squeezed and propelled the cerebrum towards the cerebellum, which was the immediate seat of the understanding!—Angels and ministers of grace defend us! cried my father,—can any soul withstand this shock?—No wonder the intellectual web is so rent and tattered as we see it; and that so many of our best heads are no better than a puzzled skein of silk,—all perplexity,—all confusion within-side."—("Tristram Shandy," Book II.)

THUS wrote Laurence Sterne nearly two hundred years ago, and in this revelation of obstetrical mysteries he presumably reflected the beliefs which were at one time held regarding the expulsive power of the uterus during parturition. The proposition that the foetal head is subjected to a force equivalent to 470 lb.—the weight of three ordinary men—was indeed calculated to awaken a lively interest. We can well understand the doubts and fears which assailed Tristram's father, and can sympathise with him when he enlisted Dr. Slop's aid and planned by exercise of obstetric art to circumvent these destructive forces, and to bring a less vulnerable part of his future offspring's anatomy to bear as Nature's battering-ram.

With the lapse of time more rational views came to be held regarding the expulsive powers of the uterus, and there is no doubt that the magnitude of the forces at work was enormously over-estimated. Many endeavours have been made to measure the precise force exerted by the parturient uterus. Matthews Duncan¹ tested the bursting strain of foetal membranes and from it deduced the expulsive power of the uterus. In more recent times various workers have measured the tone of the uterine wall by an external apparatus and from this have calculated the intra-uterine tension. Most direct and convincing of all the methods is the introduction of a hydrostatic bag into the uterine cavity itself and the measurement of the changes of pressure which are transmitted to this bag. As far back as 1872 Schatz² obtained a mechanical recording of the uterine contractions of labour by this means, and his records give an indication of the true intra-uterine tension. Some years ago Bourne and Burn,³ by a similar method, carried out a systematic investigation of uterine activity during labour, and studied the response of the uterus to drugs and anaesthetics. It will be recalled that they used a small uterine bag which could be inserted between the foetal membranes and the uterine wall high above the presenting part. This bag was connected by water-filled tubing to a mercury manometer which traced the variations of intra-uterine pressure on a slowly

* From the department of obstetrics and gynaecology of the British Postgraduate Medical School, incorporating work previously done in the obstetric unit of University College Hospital, London.

revolving drum. The records obtained by this method showed clearly the characteristics of the first and second stage labour pains and their approximate force.

Findings Obtained by the Intra-uterine Bag Method

I have repeated much of Bourne and Burn's work on the uterine forces during labour, and can corroborate their findings.⁴ During the contractions of the first stage of labour the intra-uterine tension is increased by a pressure equivalent to 35-60 mm. of mercury; 45 mm. mercury may be regarded as an average figure (Fig. 1). During the second stage of labour the contractions continue as before, and their magnitude, as a rule, is not greatly altered. In exceptional cases as, for example, after injection of pituitary extract, the tension may increase by as much as 90 mm. of mercury. A prominent new feature can be seen in the tracings obtained during the second stage: large, sudden increases of intra-uterine tension occur with the acme of each uterine contraction, and are the result of the bearing-down efforts of the patient. This "secondary expulsive power" is extremely important because, although intermittent and of short duration, it has the effect of doubling the previous intra-uterine tension. To be more exact, the additional pressure produced is the equivalent of 40-50 mm. of mercury (Fig. 2).

It is a curious fact that similar experiments made before the onset of labour pains will show the presence of uterine contractions equal, or almost equal, in magnitude to those of parturition. While these painless contractions of late pregnancy appear to differ from those of true labour only in their less frequent occurrence, it may well be that subtle differences of quality are also present, such as altered neuromuscular mechanism or retraction of the fundus uteri, which the method of recording does not reveal. It is interesting to recall that rupture

FIG. 1.—Tracing made with intra-uterine bag showing first stage labour contractions. Pressures in mm. Hg.

of the uterus occurring in the weak scar of a previous Cæsarean-section wound is an accident which happens, as a rule, not in the late stage of labour, but in the early first stage, or even during the last few weeks of pregnancy before recognisable labour pains start. This fact is readily explained by the findings just mentioned.

One small refinement in the method of recording must be mentioned. In the experiments described the deflated bag is inserted into the uterus, and the fluid pressure in the recording system is then raised to a level sufficient to cause the bag to be comfortably filled to its normal capacity of 10 c.cm. of fluid (I have always used a pressure of 25 mm. of mercury for this purpose). Recording can now begin and, as already indicated, the force of the uterine contrac-

tions above the resting tension can be measured with reasonable accuracy. Thus far, however, no allowance has been made for this resting tension of the uterus. For various reasons it cannot be measured directly. During the rest intervals the level of the tracings—i.e., the fluid pressure in the recording system—is maintained (1) by the support given to the fluid by the stretched rubber walls of the bag itself; (2) by the intra-uterine tension acting on the

FIG. 2.—Tracing made with intra-uterine bag showing second stage contractions. The dark upstrokes showing the uterine contractions are due to the bearing-down efforts of the patient. (Note: the zero level of pressure was not determined in this case, and the pressures are in consequence measured from the resting tension of the uterus.)

bag. Only the last mentioned is of interest, and it can be measured by subtracting the first; this is done by withdrawing the bag *still fully distended* from the uterus and marking on the recording chart the level to which the pressure then falls. This zero mark is shown in Fig. 1, and from it the measurements of tension are taken.

It can now be said that the pressures recorded are, on the average, as follows:—

Resting tension	15 mm. mercury.
First stage contractions plus resting tension	60 mm. "
Second stage contractions plus resting tension plus secondary expulsive force ..	105 mm. "

These measurements may be accepted as giving a generally satisfactory answer to the problem of intra-uterine pressure during labour. Certain objections, however, have been raised to the method. In particular, it has been said that the presence of a foreign body in the uterus acts as an irritant, and so produces an abnormal uterine activity. For these and other reasons an alternative method of measuring uterine powers is desirable.

A New Method of Measuring Intra-uterine Tension

The possibility of using a method which would dispense with the need for an intra-uterine bag occurred to me when watching a patient during the third stage of labour. As usual in such circumstances, each uterine contraction caused the clamped stump of the umbilical cord to become tense with blood forced into it from the squeezed placenta. Here, surely, was Nature's own intra-uterine bag with tubing presented ready for connexion to a recording manometer. Experiments soon showed that while records of uterine contractions could be obtained by these means, the observations were often marred by the partial or complete expulsion of the placenta from the fundus uteri. It was, however, an easy step to apply the new method to

a twin pregnancy and to use the placental end of the cut cord of the first delivered fœtus to record the pressures acting on the second fœtus in utero. The method is as follows:—

After delivery of the first fœtus the cord is clamped and cut as usual. The umbilical vein of the placental portion of the cord is then opened and a few c.cm. of blood allowed to escape. A small quantity of sterile sodium citrate solution is then injected into the vein in order to prevent clotting. The volume of the injected fluid should be rather less than the amount of blood which previously escaped. A glass cannula is now tied into the umbilical vein and connected by thick rubber tubing containing citrate solution to a mercury manometer which stands at the side of the bed level with the patient's uterus. The mercury column of the manometer carries a small float which presses on a slowly revolving drum in the usual

FIG. 3.—Record made by umbilical-cord method, showing pressures acting on the second fœtus of a twin pregnancy.

manner, and which thus records in graphic form the variations of intra-uterine pressure.

After setting up the apparatus a mark is made on the chart to indicate the resting position of the mercury column or zero pressure. The clamp on the rubber tubing is then released, and at once the mercury column rises to a level which represents the resting uterine tension. With each uterine contraction the mercury column rises and records a wave which is precisely similar in type to those recorded by the intra-uterine bag (Fig. 3).

The tracing which is reproduced shows the highest pressures which have been registered by this method. The resting pressure is equivalent to 25 mm. of mercury, and the uterine contractions increase this by 75 mm. of mercury, thus causing, in all, a pressure of 100 mm. of mercury to be recorded. It will be seen that the tracing is typical of first stage contractions, and, inasmuch as the second fœtus was still above the pelvic brim, this was indeed the stage of labour to which the patient had reverted at the time the recording was made. It is not usually possible to record second stage contractions because the fœtal head is then in the pelvic cavity, and the umbilical cord consequently compressed. This happened with the rupture of the membranes in the example shown.

Certain minor criticisms may be made of this method of determining pressures. (1) The pressure in the umbilical vein is, in part, the result of the tension of the fœtal vessels themselves. This causes the measurement of the resting uterine pressure to be exaggerated. The error is, however, probably small, and can be lessened by allowing the blood which escapes from the cord to be a few c.cm. in excess of the injected citrate solution. It is obvious that the method will give accurate measurements only when the circulations in the two placentas do not communicate—i.e., a binovular pregnancy. This can be ascertained after completion of labour. (2) The pressures

recorded are those produced by a partly retracted uterus acting on the second fœtus, and are not necessarily the same as those which obtain when the uterus is fully distended, for the following reasons: (a) the reduced size of the uterus makes its spherical curvature greater, and this, if other things remain equal, would result in a higher internal pressure; (b) added to this, the walls of the uterus are now thicker, and can presumably exert a greater contractile force per unit area than they could in the thinned-out condition. It is a common clinical observation that, whereas the uterus often shows a state of comparative inertia during the birth of the first of twins, it will, when it resumes activity after retraction, show a more vigorous behaviour during the delivery of the second fœtus and cause its expulsion in a very short time. The possibilities just mentioned under headings (a) and (b) give a reasonable explanation of this, and they also explain why, in the example shown, the pressures recorded were distinctly higher than those obtained by the intra-uterine bag method used in cases of single pregnancy.

The two methods of recording pressures thus provide data for an interesting comparison and, if we bear in mind the different circumstances in which the records are obtained, the results are substantially in agreement. It is particularly important to note that the main objection which has been made against the intra-uterine bag method—namely, that it provokes an abnormal activity of the uterine muscle—is proved to be without foundation, for similar, or even greater, contractions are found to occur when the uterus is not disturbed by a foreign body inserted into its cavity.

The Uterine Thrust on the Fœtus

It is now possible to make an estimate of the propulsive force transmitted to the fœtus by the intra-uterine pressure.

The part of the fœtal head which is thrust against the pelvic tissues during the second stage of labour, and dilates or canalises these structures, is limited first by the sub-occipito-bregmatic plane, and later by the sub-occipito-frontal plane. For the present purpose it will be sufficient to regard this area as being circular in outline and having a diameter of 4 in. (10 cm.). A simple calculation may then be made.

Diameter of fœtal head exposed to pressure	= 10 cm.
Area of fœtal head exposed to pressure	$= \left(\frac{10}{2}\right)^2 \times 3.14$ (area = πR^2)
	or 78.5 sq. cm.
Each sq. cm. supports a pressure equivalent to 60 mm. mercury (average).	
1 c.cm. mercury weighs	13.6 g.
∴.6 c.cm. ,, ,,	$13.6 \times 6 = 81.6$ g.
Weight supported by head =	81.6×78.5 g.
	= 6406 g., or 14 lb. (approx.).

If to this figure is added the extra pressure caused by the bearing-down efforts of the mother (equivalent on the average to 45 mm. mercury), a similar reckoning will show that the total pressure acting on the fœtal head is the equivalent of approximately 24½ lb. Similarly, if the pressures registered in exceptional cases are taken into account, as, for example, those seen after injection of pituitary extract, the total thrust exerted on the fœtal head is found to equal the weight of 32 lb.

Comparison with Other Methods

It is interesting to compare these figures with the estimation of uterine force obtained by other means. Matthews Duncan, to whom reference has

already been made, determined the pressure required to rupture foetal membranes in 100 cases. From this he deduced that the uterine contractions transmitted, on the average, a propulsive force to the foetal head of not less than 16 lb. The highest figure he obtained in this series was 37.58 lb.†

There is still another means of estimating the power exerted by the parturient uterus. This is the simple procedure of measuring the pull required to effect delivery of the foetal head by the obstetric forceps. The method is more direct, but for obvious reasons less accurate than those already described. Matthews Duncan⁵ states that a pull not exceeding 80 lb. may be required. Wylie⁶ in a recent publication gives tables of figures showing the traction required under different conditions. He states that 35 lb. is an average figure (for primigravidæ), but that his most difficult case required a pull equivalent to the weight of 74.8 lb. It must be added that Wylie measured the traction on the obstetric forceps at a time when the uterus was also contracting, and, although the uterine powers were probably considerably modified by anæsthesia, this complicating factor makes it impossible to use his figures as more than a rough estimate for comparison with those already discussed. It will be seen, however, if we accept Wylie's figures, that the force exerted during an instrumental extraction is, on the average, at least one and a half times that which is estimated to be transmitted to the foetus by the expulsive powers of normal labour. During a difficult extraction the force employed may be more than twice that which is estimated to be transmitted to the foetal head by the maximum uterine and abdominal pressures of spontaneous delivery.

THE TOTAL THRUST TRANSMITTED TO THE FŒTUS: SUMMARY OF ESTIMATIONS BY DIFFERENT METHODS

By Intra-uterine Bag Method

(a) Resting tension plus uterine contractions (average) ..	14
(b) Resting tension plus uterine contractions plus secondary expulsive powers (average) ..	24½
(c) As in (b) but after pituitary extract injection ..	32

By Fatal Cord Method

Resting tension plus uterine contractions	23½
---	-----

By Bursting Strain of Foetal Membranes †

Average measurement	16
Greatest measurement	37.58

By Traction on Obstetric Forceps

Average traction (for primigravidæ)	35
Greatest traction	74.8

Conclusions

1. Various methods are described by which the intra-uterine pressure during labour may be measured.
2. A new method of measuring intra-uterine tension and of recording uterine activity without use of intra-uterine apparatus is presented.
3. The intra-uterine resting tension is equivalent to a pressure of about 15 mm. mercury.
4. First and second stage uterine contractions cause a pressure equivalent, on the average, to 60 mm. mercury.
5. Contractions of nearly equal magnitude can be recorded before the onset of true labour pains.
6. During the second stage of labour the bearing-down efforts of the patient bring an extra pressure of about 45 mm. mercury to bear on the foetus.

† Matthews Duncan assumed that the area of head in contact with the pelvic tissues measured 4½ in. in diameter; on the same basis my own figure would read 18 lb., 32 lb., and 41 lb. instead of 14 lb., 24½ lb., and 32 lb.

7. From these pressures the total thrust transmitted to the foetus during parturition can be estimated.

WHAT IS SCARLET FEVER FOR THE CLINICIAN?

By F. G. HOBSON, D.S.O., D.M. Oxon.,
F.R.C.P. Lond.

PHYSICIAN TO RADCLIFFE INFIRMARY AND COUNTY
HOSPITAL, OXFORD

IN 1899 "The Infectious Diseases (Notification) Act" became law throughout England and Wales, and included in the schedule of compulsorily notifiable diseases is the disease "Scarlet Fever." The penalty for failure to notify a case of this disease is 40s.

Upon the clinician in charge of a case rests the responsibility for diagnosis and notification, and it is pertinent therefore to review a situation in which he is placed not once but many times each year.

Reference to any text-book of medicine will show that the disease "Scarlet Fever" is defined in such terms as these: "An acute infectious disease due to a streptococcus characterised by inflammation of the fauces and a punctate erythematous rash followed by desquamation, and associated with a special liability to nephritis and otitis media." However much an individual clinician may recast or amplify these terms, it is impossible to omit "the punctate erythematous rash" which is the "scarlet" feature of the fever, and of diagnostic and therefore of notifiable significance. Every clinician after a few years of practical experience must ask himself certain questions:—

1. If the above definition in truth describes accurately the picture presented by a relatively small group of patients suffering from streptococcal infections, has it any merit other than its "classical attribute"?

2. If the notification of "Scarlet Fever" is confined to cases of the "classical" type, would it not be as rational to confine the notification of meningococcal fever to those cases which are "spotted"?

3. If the purpose of notification is to identify and segregate those liable to disseminate an epidemic disease, is the incidental and relatively unimportant development of a punctate erythema to be the only criterion?

4. Is it of any value to retain the name "Scarlet Fever" in the schedule of notifiable diseases, from the clinical or epidemiological point of view?

This is the problem, and before considering the clinical evidence it will be valuable rapidly to review the historical, bacteriological, and clinical aspects.

HISTORY AND EPIDEMIOLOGY

Rolleston, among many others, has remarked that "Scarlet Fever was very mild a century ago, fifty years ago it was extremely malignant, and now again it is a mild infection, although its prevalence cannot be shown to have diminished."¹ If this is true and "Scarlet Fever" was and is a specific disease, the alteration in its clinical character is due to an alteration in the virulence or prevalence of the specific causal organism or the constitution and composition of the population affected.

Bacteriology lends no support to the view that the specific causal organism has altered its character; indeed there is no specific organism, although there are erythrogenic streptococci of many types.

Epidemiological research has shown that the spread of disease is a function of the environment, and changes in social, sanitary, economic, industrial, and domestic conditions may have an important effect on the population, influencing the prevalence and spread of infection.

Absolute and statistical proof or disproof of the statement that "Scarlet Fever" has changed its clinical characteristics is impossible because of the indefinite name, and the entire absence of bacteriological data over the period covered.

The strongest inference that can justly be drawn from the records is that the *erythematous* feature has varied in epidemics of different malignancy.

The "scarlet" feature was giving trouble some forty years ago when "Scarlet Fever" was generally a severe disease, as is shown by the question raised by Dr. Clement Dukes, "Is there a Fourth Disease"? The Fourth Disease (Duke's disease) was in time succeeded by a fifth disease, Erythema Infectiosum, and eventually by a sixth disease, Exanthema Subitum.²

BACTERIOLOGY

In 1923 the Dicks isolated a strain of *Streptococcus hæmolyticus* which produced typical cases of "Scarlet Fever" in the susceptible, and demonstrated that after an attack a Dick-positive patient became Dick negative. The hope that the mysteries of the origin, infectivity, and clinical features of the disease had been removed proved false when further work revealed 27-30 strains of this streptococcus, *hæmolytic* but not necessarily associated with an erythema. There appear to be instances of the association of *non-hæmolytic* streptococci with a typical erythema and the clinical features and sequelæ of "Scarlet Fever."

The Schulz-Charlton reaction, at first regarded as "specific," is now known to be specific only in the identification of an erythema as due to a strain of streptococcus identical with the strain employed in the production of the antitoxic serum used in the test. This reaction regarded by some clinicians as of value in both prognosis and therapy finds this application only in approximately 50 per cent. of cases diagnosed as "Scarlet Fever" of the "classical" type.

The most that bacteriology can offer may be summarised as follows:—

1. Many strains of streptococci produce an exotoxin containing, among other noxious properties, an erythrogenic factor, this factor being most characteristic of the highly toxigenic hemolytic strains, which are associated with the more virulent infections of the throat, skin, connective tissues, and uterus.

2. The development of an erythema depends not solely upon the erythrogenic factor but also upon the susceptibility of the infected individual to it.

Bacteriology has rendered a signal service to clinical medicine by proving that all cases of "Scarlet Fever" (in the classical sense) are due to a streptococcus, most frequently of the hæmolytic type.

Bacteriology confirms clinical experience in demonstrating that the "Scarlet" feature is no more than a partially specialised reaction, depending for its development upon two factors, the bacterial strain and the susceptibility of the patient.

"Scarlet Fever," though essentially bacterial in origin, flouts all the postulates of Koch and is barely

able to support the dignity of a syndrome, yet it is a notifiable disease in an age in which the identification and classification of diseases is a striking feature of the progress of medical thought.

CLINICAL MEDICINE

It is the clinician who has to face this grave and difficult problem with its many absurdities, when he has to treat not only his patients but also their neighbours as contacts.

In the interests of medical practice and public policy a reconsideration of the whole position is long over-due.

In one sense the position is clear: when the clinician notifies an identified erythema, and segregates the patient under suitable conditions, his legal responsibility is discharged, the public conscience is satisfied, quarantine is observed by all contacts, and the erythematous patient is tended with all the care and devotion that the disasters of previous experience have shown to be necessary. The public is prepared for complications by the reputation of the disease. But what of the patient who develops no erythema? Many clinicians experienced in the subject have noted that in epidemics of streptococcal infection—

1. A hæmolytic streptococcus has been demonstrated in many cases which could not be called "Scarlet Fever."

2. The liability to serious complications appears to be slightly greater *without an erythema*. If there is a rash a *negative* Schultz-Charlton reaction is an unfavourable sign.

3. In household infections of streptococcal sore-throat, an erythema develops in only a few cases.

4. The infectivity is identical *with or without an erythema*.³

In other words the erythema is a favourable sign, and yet notification and strict isolation is reserved for those cases alone. "It is well known that, in so far as controlling an epidemic is concerned, the rigid hospitalisation of every case of 'Scarlet Fever' has completely failed."

The position which the later clinical evidence will illustrate is that streptococci pathogenic to man, with a strong invasive tendency, give rise to a wide complex of pathological states, which have a close consequential relationship one with another.

There may be a toxæmia, from the absorption of exotoxin from the organisms in a primary focus, or there may be dissemination of the actual organisms from such a focus with secondary lodgment in distant organs, by a transitory bacteriæmia, or lastly the organisms may enter and multiply in the blood stream giving rise to septicæmia.

From a primary focus there may develop one or all of these sequelæ, the path of dissemination being by the lymph stream, or by the blood stream, or by both. Each of these states may develop *with or without an Erythema* even when due to a streptococcus of the Hæmolytic type. There are cases in which an Erythema develops apparently in association with a Non-hæmolytic Streptococcus, and the clinician is tempted to wonder whether there is not a bacterial no-man's land in which there are to be found strains of streptococci possessing the Erythrogenic but not necessarily the Hæmolytic factor.

If it can be shown that streptococci of various types can, *with or without an Erythema*, produce pathological lesions strictly comparable from the clinical and epidemiological standpoints the case for the abolition of "Scarlet Fever" from the clinician's vocabulary is proved.

The cases are drawn from personal, hospital, or private practice, and are not in themselves dramatic or unusual. From medical literature the evidence could be amplified a hundredfold.

TERMS USED IN CLINICAL REPORTS

1. The erythema or rash—the “classical” fine punctate erythema, which is supposedly characteristic of “Scarlet Fever,” is implied where this term is used without qualification.
2. Desquamation and the appearance of the tongue are (usually) noted.
3. In most instances differentiation of the streptococcus involved has been carried no further than the distinction between “hæmolytic” and “non-hæmolytic.”

CASES OF TONSILLITIS OR PHARYNGITIS WITH AND WITHOUT ERYTHEMA

1. Mrs. J-J, Miss M. J-J, and Miss E. J-J stayed with friends suffering from “sore-throats.” Sept. 11th, 1934.—Miss M. J-J developed an attack of acute tonsillitis with no rash; no sequelæ. The family returned home on the 16th. 19th.—Mrs. J-J (scarlet fever as a child) developed a very severe and acute tonsillitis; no rash and no sequelæ. 26th.—Miss E. J-J developed an acute tonsillitis and on the 27th a rash, later a typical strawberry tongue and desquamation; no further sequelæ.

Comments.—Swabs from all throats had hæmolytic streptococci. Miss M. J-J (the original case) still showed hæmolytic streptococci on Oct. 15th. By law, only Miss E. J-J was notified. Similar family groups are met with again and again.

2. A small epidemic in a school of 95 boys (Table I.).

TABLE I

Admissions to sanatorium.	
March 5th, 6th, 7th, 1933	6 boys with acute pharyngitis and acutely inflamed glands of neck.
March 14th	1 boy with the same clinical features.
March 28th, 31st	5 boys
April 4th	2 boys

Comments.—Each of the 14 boys had a tonsillectomy before entering the school; no one with intact tonsils was involved. The clinical picture presented by each was identical, the onset being acute with high fever and severe toxæmia. Five boys were discharged 10–12 days after admission; nine boys were ill for 21–35 days. Hæmolytic streptococci were demonstrated in the swabs taken from one member of each group.

Boy No. 1 was a case of acute and severe illness with high remittent fever for five weeks, a rigor with a temperature of 104° in the fourth week (presumably a

transitory bacteriæmic shower) and acutely inflamed lymphatic glands. The glands eventually subsided without suppuration.

Boy No. 12, admitted with acute pharyngitis and lymphadenitis, on the second day developed an acute otitis media (left) with instantaneous perforation; on the fourth day a general rash with subsequent desquamation. Operation later for left mastoiditis.

By law, only No. 12 was notified.

3. A small epidemic in a school of 75 boys (Table II.).

TABLE II

Admissions to sanatorium.		Throat swab.
1. Ev.	June 1st. Acute tons.; vomit ..	Not done.
2. D.	3rd. Ditto; erythema on second day.	Hæm. strept.
3. B.	8th. Acute tons. ..	Non-hæm. strept.
4. C.	14th. Acute gran. pharyngitis; no rash; no sequelæ.	Hæm. strept.
5. H.	29th. Acute tons.; vomit	Non-hæm. strept.
6. V.	30th. Ditto.	
7. R.	1st. July. Ditto; erythema on second day.	
8. Ed.	9th. Acute tons. ..	

Tons.=tonsillitis. Hæm. strept.=hæmolytic streptococcus.

Other admissions to sanatorium in the above period consisted of minor sepsis and trauma.

The swabs were all taken personally on the first day of admission to the sanatorium (temp. 102–103°) and were examined for K.L.B., hæmolytic, and non-hæmolytic streptococci.

Boy No. 2 produced a typical erythema, tongue and subsequent desquamation without sequelæ, the infection being due to a hæmolytic streptococcus.

Boy No. 7 produced a typical erythema well developed over the back, lower abdomen, groins, and thighs—“bathing drawers” type—but lasting only 24 hours, the infection being due to a non-hæmolytic streptococcus. In all cases the attacks were mild and recovery rapid. No. 2 and No. 7 showed no feature other than the erythema to distinguish them from the remainder. The urine in no case showed any albuminuria during the third week, after the initial tonsillitis.

4. An epidemic in a school of 371 boys.—The material for this report has been kindly submitted to the writer by a colleague who, with the M.O.H., supervised the epidemic. The school is residential, and there are 338 boarders and 33 day boys. The boarders live in “houses” and have a common dining-room and the boys also mix in the house dormitories and day-rooms. The history of the epidemic is shown in the chart.

In the first half of February there was an outbreak of "influenza" with sore-throats, temperatures, coughs, and profuse nasal catarrh.

Difficulty was experienced in controlling the epidemic for the following reasons:—

(a) The cases were not confined to any particular house, dormitory, classroom, or dayroom, and as the boys mixed in all four places, practically the whole school had been exposed to infection. Isolation and detection of contacts was impossible.

(b) The original cases were missed because of an epidemic of sore-throats, cough, and coryza, possibly influenzal, and the rashes might have been the result of influenza.

The Dick test was unreliable in this epidemic of type V. (Franklin) hæmolytic streptococci; and too much reliance was placed on a negative result in the presence of an atypical symptom.

(c) The catarrhal symptoms in the "influenzal" epidemic would tend to increase the danger from normal carriers.

The Schultz-Charlton reaction was reliable in the presence of a good rash, but the reaction was sometimes delayed for 48 hours.

The endemic cases of scarlet fever in the town at this time were due to type I. hæmolytic streptococci (Table III.).

The typing of the streptococci was carried out by Dr. F. Griffith of the Ministry of Health.

TABLE III

Cases Analysed According to Type of Erythema

Remarks.	Erythema.			
	"Class-ical."	Atypical and trans-sient.	"Sur-gical."	Absent.
55 cases	34	14	1	6
Streptococcus type V. ..	19	5	—	4
type XI. ..	—	—	—	1
Untyped	15	9	1	1
Complications	18	3	1	3

Analysis of Complications

Total=25 (approximately 1 in 2)

	"Class-ical."	Atypical and trans-sient.	"Sur-gical."	Absent.
Rhinitis	5	—	—	—
Adenitis	2	—	—	1
Otitis media (operation) ..	—	—	—	2
Mastoiditis (operation) ..	3	—	—	—
Quinsy	1	—	—	—
Carditis	—	1	1	—
Carditis and arthritis ..	—	—	—	—
Carditis and rheumatism ..	—	1 (D)	—	—
Adenitis and rheumatism ..	3 (1*)	—	—	—
Rheumatism	2	—	—	—
Sinusitis; cerebral abscess ..	1	—	—	—
? Mesenteric thrombosis ..	1 (D)	—	—	—
Total	18	3	1	3
Streptococcus type V. ..	16	3	—	2
type XI. ..	—	—	—	1
Untyped	2	—	1	—

* Developed a late albuminuria. D=death.

Comments.—In the six cases "erythema absent" the diagnosis was established as follows:—

- 1 case (No. 2); tonsillitis, Feb. 3rd, 1935; desquamation, March 6th, 1935.
- 1 case (No. 45); otitis media-paracentesis type V. streptococcus.
- 1 case (No. 39); temperature; headache; type V. streptococcus.
- 1 case (No. 44); tonsillitis; type V. streptococcus.
- 2 cases (Nos. 32, 43); mastoiditis; operation; type V. streptococcus.

These six cases without erythema almost certainly do not represent the true total in this group when it is recognised (see diagram) that there were 48 cases of "sore-throat and temperature" and 77 cases of "influenza."

In the next term there were nine further cases of scarlet fever, the streptococcus type III. being demonstrated in two cases and an untyped hæmolytic streptococcus in one case (Table IV.).

TABLE IV

Remarks.	Erythema.			
	"Class-ical."	Atypical and trans-sient.	"Sur-gical."	Absent.
9 cases	6	2	1	—
Streptococcus type III. ..	1	1	—	—
hæmolytic ..	1	—	—	—
Untyped	4	1	1	—
Complications	1	2	—	—

Analysis of Complications

Total=3 (1 in 3)

Measles; pneumonia ..	1 (D)	—	—	—
Vincent's angina	—	1	—	—
Measles; mastoiditis; bilateral operation ..	—	1	—	—

D=death.

Comments.—1. "Surgical" mosquito bite June 18th, 1935; sore-throat; rash June 21st.

2. Atypical cases.

1 case (No. 59); Vincent's angina June 24th; faint "bathing drawers" rash June 28th.

Subsequent desquamation.

1 case (No. 62); measles, atypical rash ? mixed infection; double mastoid operation; type III. streptococcus.

3. 1 case complicated by measles, pneumonia, and death, showed type III. streptococcus.

The conclusions which can be drawn from these epidemic groups are as follows:—

- 1. The appearance of an erythema was fortuitous and without special clinical importance.
- 2. It was significant only in that it was evidence that an erythrocytic streptococcus was involved.
- 3. The early cases of each group which from the epidemiological point of view should have been isolated had no erythema. To notify only the cases with a rash gave a false impression of the extent or virulence of each epidemic.

Bacteriological research is proving that certain strains of streptococci cause epidemics in which severe complications are pronounced *with or without an erythema*, and early recognition of prevalence of these strains in the community would be valuable. To the clinician in charge of a school or family this information would be of special value. Precautionary measures can be exercised such as isolation and appropriate prophylaxis against dissemination can be adopted. The serious or fatal complications of streptococcal epidemics in the community in general and in schools in particular present a problem as urgent and important as that of diphtheria or any other epidemic disease.

SEPTIC SCARLET FEVER AND SURGICAL SCARLET FEVER

The classical case from which the Dicks isolated and proved the infectivity of the scarlatinal streptococcus may well be quoted:—

The patient was a nurse who was attending an ordinary case of scarlet fever. For two days before the onset of her own attack she had a sore finger. The pus from which the Dick cultures were obtained was taken from the finger on the second day of her scarlatinal attack. It is now a matter of history that it was by swabbing the throats of volunteers with these cultures that the Dicks produced two typical cases of scarlet fever.

Another case referred to by Dr. C. R. Box 4:—

A superintendent medical officer at the London Fever Hospital, when dressing a suppurating gland in the neck of a scarlet fever patient, infected an abrasion on his finger. The axillary glands rapidly swelled up accompanied by high fever and a rapid pulse. A hæmolytic streptococcus was grown from the blood and in a few days he was dead from streptococcal septicæmia. *In this case no scarlatinal rash was seen*, but there was no doubt as to the source of the infection.

An Erythema is unusual in septicæmia due to a Hæmolytic Streptococcus. (Compare Case 2 in next clinical group, where the portal of entry was in the tonsils.)

G. B., aged 30, engineer. July 8th, 1935.—Small abrasion right thumb, dressed with iodine; scabbed over. 12th.—Scab knocked off; iodine applied; on the same day he dropped a heavy weight on toes of right foot. 14th.—Vivid lines of acute lymphangitis covered with vesicles extended from thumb abrasion to axillary lymph glands which were acutely inflamed and tender. 15th.—Vivid lines of acute lymphangitis covered with vesicles extended from injured toe to right inguinal group of glands which were acutely inflamed. 16th.—*Typical general scarlatiniform rash*; throat injected; a superficial dermatitis of the foot which developed from the infected toe clefts took some three weeks to clear up.

Comment.—The history suggests that the infection from the original wound on the thumb was inoculated while dressing the foot. The whole illness was strikingly mild, the temperature on one day reaching only 100° F.; apart from the dermatitis of the foot convalescence was uneventful.

CASES OF TONSILLITIS WITH A BACTERIEMIA OR SEPTICÆMIA WITH AND WITHOUT ERYTHEMA

1. Mrs. D. D., aged 22. July 3rd, 1935.—Delivered by midwife; small perineal tear; two stitches. 4th.—Rash noted by patient; two or three attacks of shivering. 5th.—Admitted to hospital: typical scarlatiniform rash, acute tonsillitis, pharyngitis, and local adenitis (confirmed by M.O.H.), labia tender and oedematous; uterus involuting normally; lochia normal and copious. 6th.—Antiscarlatinal serum 40 c.cm. 7th.—Antiscarlatinal serum 40 c.cm. 8th.—Typical strawberry tongue, rash fading, fauces injected; swab from fauces—*non-hæmolytic streptococcus*. 11th.—Blood culture positive, *hæmolytic streptococcus*. 12th.—Human serum intravenously from 80 c.cm. of whole blood. 14th.—Human serum intravenously from 50 c.cm. of whole blood. 17th.—Blood culture negative; swinging pyrexia. 23rd.—Fluctuant swelling over sacrum and trochanter (left) freely incised; nil found; branny desquamation. 26th.—Pyrexia continued; blood culture negative. August 6th.—Swelling over sacrum again incised; fluid pus containing streptococcus (untyped); fever subsided. Convalescence uneventful.

Comment.—Two possible portals of infection—fauces associated with a non-hæmolytic streptococcus; perineal tear associated with hæmolytic streptococcus. Classical picture of "Scarlet Fever," associated with a bacteriæmia due to hæmolytic streptococcus, metastatic abscess, and recovery.

2. V. S., aged 42. Nov. 9th, 1932.—Sore-throat. 11th.—Acute tonsillitis; T. 103° F. 14th.—Fauces clear; two tender glands in posterior triangle of neck (left). 15th.—Fauces clear; acute rhinitis; glands less tender; rigor; T. 104° F. Blood culture: hæmolytic streptococcus in all tubes in 12 hours. 16th–20th. Daily. Antiscarlatinal serum intravenous, 50 c.cm. Antiscarlatinal serum intramuscular, 15 c.cm. 21st.—Death. There was no rash.

Comment.—Acute tonsillitis, lymphadenitis, septicæmia due to hæmolytic streptococcus without a rash followed by death.

3. S. F., aged 12. 23 out of 75 boys were admitted to the school sanatorium between April 29th and July 25th with tonsillitis, all with mild attacks and without erythema

or complications. The streptococcus involved was not typed.

July 1st–5th, 1934.—Acute pharyngitis (tonsils had been removed). 5th–13th.—Pharynx clear; acute adenitis. 14th.—Consolidation left apex, small area; acute arthritis, left hip aspirated; (report—polymorphs and endothelials). Culture negative. Blood culture positive—*non-hæmolytic streptococcus*. The boy was very acutely ill and in the course of a few hours' sleep developed a sacral bedsores. 15th.—Effusions into right knee, wrist, and shoulder and left hip. 16th.—Effusions into right and left knees and left hip, right and left ankles, right shoulder and wrist. 17th.—Left apex clear; effusions subsiding. 20th.—Effusion into interphalangeal joints, right forefinger; a soft apical systolic murmur became evident about this time, and subsequently signs of a definite myocarditis, which involved a prolonged convalescence.

Comment.—Acute tonsillitis, lymphadenitis, bacteriæmia due to *non-hæmolytic streptococcus*, multiple arthritis, carditis, without a rash. The case is quoted to emphasise the similarity with a clinical picture not uncommon in "Scarlet Fever" associated with arthritis and carditis.

DISCUSSION AND SUMMARY

The illustrative clinical cases quoted above prove that:—

1. An erythema is inconstant in infections due to a hæmolytic streptococcus.
2. It may be a feature of those due to a non-hæmolytic streptococcus.
3. Though it is more frequent in infections due to hæmolytic streptococci, it is a poor guide to the course, prognosis, or infectivity of the disease in a given patient.
4. Infections due to hæmolytic streptococci *with or without an erythema*, are generally highly toxic, highly infectious, and have a striking association with sequelæ of all kinds. *The appearance of an erythema is probably a favourable sign.*
5. An infection due to a non-hæmolytic streptococcus may have sequelæ in no way distinguishable from those due to a hæmolytic strain, whether there is an erythema or not.

If these statements and conclusions are sound it is pertinent to consider what alterations or modifications of clinical practice and teaching should be introduced.

Firstly, the executive and primary object of notification is to segregate those liable to spread an epidemic disease, and to effect this, suitable hospital accommodation is provided which must be used when the home conditions cannot ensure proper isolation.

It is admitted by every medical officer of health that strict hospitalisation in cases of streptococcal fever that develop a rash has completely failed to control epidemics, and this is supported by clinical evidence.

The notification of "Scarlet Fever" as at present practised serves no useful purpose; indeed, it is probably of disservice from the executive standpoint because it confines valuable hospital accommodation to a selected group. The accommodation could be better employed for cases of streptococcal infections selected on clinical grounds or for domestic reasons, rather than by an Erythema. A much higher standard of isolation is essential because the inmates are not all suffering from the *same disease*.

Secondly, the public is still prone to regard tonsillitis as a trivial complaint, and is still uninformed of the disasters which may follow the neglect of simple precautions; the profession has, in this respect, neglected its educational function.

Isolation of the patient in the home, the use of separate feeding utensils, and masking or gargling by the attendants, is generally neglected and should be enforced. To confine patients to bed for a minimum of 7–10 days, and to examine the urine in the

third week are two measures of obvious clinical value.

Thirdly, the use of a swab as a public health measure could, with value to the clinician, be used not only to identify the Klebs-Löffler bacillus but also the Hæmolytic or Non-hæmolytic Streptococci. To know the type of streptococcus present in a given case would be of real value to the clinician in charge.

Fourthly, an increasing number of experienced clinicians believe that it is of proved value to give so-called antiscarlatinal serum in the early therapy of infections due to Hæmolytic Streptococci to relieve symptoms and to prevent complications. The public health services should therefore provide the serum for use in hæmolytic infections on the same basis as it provides serum for the treatment of Diphtheria.

CONCLUSIONS

1. "Scarlet Fever" even if descriptive of a clinical entity has no claim to retention in the clinician's vocabulary of diseases.

The dermatological or more accurately the vascular manifestations of an infection due to a streptococcus or a meningococcus are in themselves of minor clinical importance.

2. The term "Spotted Fever" has been expunged from scientific medical nomenclature, and the time has come for "Scarlet Fever" to suffer a similar fate.

The retention of the term "Scarlet Fever" in the schedule of notifiable diseases is of no service to the patient, the public, or the profession.

The writer wishes to record his thanks to Dr. G. C. Williams, Dr. J. Frankland West, and Dr. A. D. Gardner for valuable assistance.

INTRAVENOUS ANÆSTHESIA WITH PENTOTHAL SODIUM

BY RONALD JARMAN, D.S.C., M.R.C.S. Eng., D.A.
ANÆSTHETIST TO THE CANCER HOSPITAL; SENIOR ANÆSTHETIST
TO THE PRINCESS BEATRICE HOSPITAL, GORDON HOSPITAL,
AND WOOLWICH WAR MEMORIAL HOSPITAL; AND

A. LAWRENCE ABEL, M.S. Lond., F.R.C.S. Eng.

SURGEON TO THE PRINCESS BEATRICE HOSPITAL AND THE
GORDON HOSPITAL FOR RECTAL DISEASES; ASSISTANT
SURGEON TO THE CANCER HOSPITAL AND TO
THE WOOLWICH WAR MEMORIAL HOSPITAL

It is natural that there should be some hesitation about injecting into the circulation a drug which cannot afterwards be withdrawn, and therefore objection is sometimes taken to the intravenous use of barbiturates for anæsthesia. Against this, however, we have the fact that they are used in extreme dilution and katabolised extraordinarily rapidly, leaving no ill-effects behind them. In our opinion this makes them less obnoxious than ether, chloroform, or any form of inhalation anæsthetic except nitrous oxide-oxygen. The avoidance of a sense of suffocation and of almost all psychic shock, the remarkable freedom from vomiting, and the absence of delayed poisoning, together with the complete safety of intravenous anæsthetics in our hands in many thousands of cases, have encouraged us to continue this line of clinical research and extend it to the use of Pentothal, which we met in America

sixteen months ago and introduced into this country by the kindness of Messrs. Abbotts, while it was still in its experimental stage as "8064."

The barbiturates used for intravenous anæsthesia fall into two groups: heavy and light. The heavy, including Nembutal, Pernocton, Sodium Amytal and Di-dial, are slowly broken down and are found in excretions up to 72 hours after administration; accordingly we prefer to use them as narcotics and not as general anæsthetics. The light barbiturates, Evipan sodium, Eunarcon, and Pentothal sodium are broken down so fast that barely a trace can be found in excretions after 12 hours. For all practical purposes their effect has passed off in from 3 to 30 minutes, according to whether a minimal or normal dose has been used. Provided reasonable precautions are taken they appear to us to be quite safe for all minor operations, and as a means of induction or total anæsthesia for a very large proportion of major operations.

ADMINISTRATION

For minor operations—e.g., dental extractions, the opening of boils and whitlows, the removal of nails, and the setting of fractures—no preliminary medication is needed and only the minimum dose required to produce surgical anæsthesia should be used. Usually 3 c.cm. of evipan or pentothal are sufficient. For major operations on patients in an institution we use premedication with omnopon and scopolamine.

The intravenous anæsthetic may be administered in one of three ways:—

(a) *As a single dose.*—This is used for an operation which is likely to last from 10-20 minutes—e.g., cesophagoscopy, bronchoscopy, cystoscopy and cysto-diathermy, sigmoidoscopy, and dilatation and curettage.

(b) *Repeated doses.*—If the effect of the anæsthetic begins to pass off, a second or even third dose may be administered by the intravenous route.

(c) *By continuous intravenous infusion.*

Any operation which is found to take longer than was anticipated may have its anæsthetic supplemented either by a further intravenous dose as described above, or by an inhalation anæsthetic.

Pentothal sodium* is supplied in ampoules each containing 1.0 gramme, together with a separate ampoule containing 10 c.cm. of sterile distilled water. It is a yellow crystalline powder and when 1.0 g. is dissolved in 10 c.cm. of water it produces a gaseous solution which takes a moment or two to clear and is then ready for use. The gas given off during the mixing is of the H₂S type. It is important to see that there is no precipitate. We have now used it in more than 1000 cases, and may briefly describe its effects as follows.

EFFECTS

The *induction period* is as dramatic, smooth, and pleasant as with evipan. Most patients go to sleep without yawning, but occasionally they yawn as with evipan.

Respiration.—One of the most important points to note is that in using this drug for surgical anæsthesia the respirations become shallow, but their rate and rhythm remain unchanged. If the anæsthetic is injected too quickly, the respirations may

* Thio-barbiturate pentothal sodium has been known under the name of thio-barbiturate 8064. Messrs. Abbotts, of Chicago and Montreal, kindly allowed us an unlimited supply of this as well as a small quantity of the closely allied drug thio-barbiturate 8076. In view of the excellent results obtained by our friends, Dr. A. L. Tatum and Dr. R. M. Waters, both of Madison, Wisconsin, we decided to use it in this country, and this was done in collaboration with Dr. J. S. Lundy, of the Mayo Clinic.

become imperceptible, and it is therefore advisable to allow a double safety pause during the administration of this drug. When it is carefully injected the respiratory depression is not great, and in any case is rapidly overcome by healthy young adults. In older people the return to normal is delayed.

The *airway* is of vital importance, and an appropriate dental prop must be inserted before the anæsthetic is given. If the respiration becomes too depressed oxygen or CO₂ and oxygen may easily be administered via the Hewer's airway, which may with advantage be replaced by a Phillips's airway as soon as the patient is unconscious. Throughout the injection the angle of the jaw must, of course, be supported, with the head on one side or partially extended.

Colour.—Often the patient becomes slightly cyanotic, older patients more than younger. A well-maintained airway, with or without a little oxygen, soon restores the colour.

The *pulse* quickens as soon as the first two or three cubic centimetres have been given. It gradually loses some of its volume, but returns to normal within a few minutes. If strict attention be paid to the patient's colour, the pulse does not become weak.

The *pupil* first dilates, but soon becomes normal. The corneal and conjunctival reflexes are lost for the whole time that the drug is acting as a surgical anæsthetic. As soon as it starts to wear off, the reflexes return to normal.

No *tremors* have been seen except where the minor operation had been started before complete surgical anæsthesia had developed. In this case, tremors started and took two or three minutes to disappear.

Recovery.—Most patients recover a little more quickly than with evipan, and their minds are clearer. We have observed no case of post-operative restlessness and no cause for anxiety, provided the airway has been properly maintained. Varying degrees of post-anæsthetic drunkenness occur, but this passes off more quickly than after evipan.

Accidents.—If a small or greater part of this solution is injected into the subcutaneous tissues there will be a little local reaction. It is of course important that the syringe and needles are free from all spirit. If the drug is given too quickly there is a dangerous depression of the respiratory centre.

ADVANTAGES AND DISADVANTAGES

The only drug in use as an intravenous anæsthetic with which we can compare pentothal is evipan, and we have no small difficulty in comparing and contrasting these. The main differences which we have noticed are:—

1. Induction with pentothal is a little smoother.
2. Pentothal scarcely ever produces the twitching or jactitation which we have occasionally seen with evipan.
3. The fall in blood pressure is less noticeable than with evipan.
4. The main disadvantage of pentothal is that it is more depressant to the respiratory centre, and for this reason we always like to have a McKesson apparatus at hand to administer oxygen and carbon dioxide under pressure if required.
5. A few patients have complained of a sulphurous taste or smell for a short time after the administration of pentothal.

CONTRA-INDICATIONS

Liver.—These light barbiturates are metabolised in the liver very rapidly, and any gross hepatic disease or the presence of jaundice is a definite contra-indication.

Low blood pressure.—General feebleness of the patient and low blood pressure make it inadvisable to use doses liable to cause a definite fall in blood pressure.

Posture.—Owing to the fall in blood pressure with all intravenous barbiturates, the recumbent posture is the safest for the administration of these anæsthetics. Several untoward effects have been encountered in the dental chair even with healthy patients.

Space.—Lack of available space applies only to institutions where a large number of patients are to be dealt with and where enough room is not available to allow all of them to recover sufficiently to return home.

Other barbiturates.—As a general rule it is not advisable to give any barbiturate intravenously after other barbiturates have been given as premedication.

ANTIDOTES

The antidotes to pentothal do not differ from those of any other form of general anæsthetic, nor are they more often needed. Coramine is by far the most reliable drug for collapse and it should be used liberally. Five cubic centimetres are the average dose, and 10 c.cm. may be given for severe collapse. It may be given subcutaneously or intramuscularly, or, in a case of emergency, intravenously. It has a stimulating effect on the heart and respirations. Alpha-lobeline is a direct respiratory stimulant and is used in doses of gr. 3/20, or 3/10, either subcutaneously or, in urgent cases, intravenously. Another direct respiratory stimulant is carbon dioxide. It is given, of course, by mouth, preferably under pressure in the proportion of 5 or 7½ per cent. CO₂ in oxygen. A cylinder of this mixture should be in every operation-room and in every recovery-room.

Though it has proved possible to kill animals with pentothal no pathological changes could be discovered in their organs post mortem apart from signs of respiratory failure.

AFTER-EFFECTS

In our series of over 1000 cases there have been no deaths following the use of pentothal sodium, nor does any pathological process appear to have been aggravated. No patient who has had pentothal alone has vomited after an operation. Vomiting has occurred in a very small proportion of those cases that have had premedication in addition to pentothal, but the proportion was no greater than after taking an opiate alone, and was much less than after an ordinary inhalation anæsthetic.

We regard pentothal sodium as a worthy addition to our list of safe and satisfactory intravenous anæsthetics.

PRINCESS ELIZABETH OF YORK HOSPITAL, SHADWELL.—Mr. Meyerstein has promised to pay £5000 for the 25 acres of hillside at Banstead which face the site where the new hospital is to be built. This will keep the prospect open for ever. Mr. Meyerstein is also giving £10,000 towards the cost of the new building.

NEW HOSPITAL FOR SCARBOROUGH.—When the new hospital is opened at Scarborough, additional maintenance costs will have to be met and the authorities have decided to launch a contributory scheme under the British Hospitals Contributory Scheme Association. The new building will have 140 beds, the present hospital has 70, and the annual expenditure it is estimated will be between £12,000 and £15,000. Under the scheme it is proposed that the weekly contribution shall be 3*d.* for adults and 2*d.* for those over sixty and under twenty-one.

TREATMENT OF PSYCHOSES BY PROLONGED NARCOSIS

By D. N. PARFITT, M.D., M.R.C.P. Lond., D.P.M.

DEPUTY MEDICAL SUPERINTENDENT, WARWICKSHIRE AND
COVENTRY MENTAL HOSPITAL

The treatment of psychoses by prolonged narcosis has been popular on the continent for some years and has proved so effective in manic-depressive states that a diagnosis of mania or melancholia is considered doubtful if no improvement follows prolonged narcosis therapy.

After careful physical investigation and the administration of an enema, the patient is put to bed in a single room and every effort made to ensure absolute quiet. The most favoured drug is Somnifaine given in 2 c.cm. doses by intramuscular injection in sufficient quantity to ensure continuous sleep for 10-12 days, feeding with fluids being carried out before each injection and at intervals when possible. Poisonous symptoms are unfortunately very common and have prevented the more general adoption of the treatment. Thus early collapse, or a condition similar to "veronal pneumonia," or great difficulty in swallowing combined with oedema of the throat and an excessive secretion of mucus, may occur, and other less serious or less common symptoms are muscular incoördination, irregular and sometimes high pyrexia, a fall of blood pressure, hyperidrosis, various rashes, albuminuria with or without casts, oliguria, anuria, and epileptiform convulsions. Added to these is a liability to contract pulmonary infections.

Investigations at the Cardiff City Mental Hospital by Quastel and Wheatley¹ and Quastel and Ström-Olsen² having shown that narcosis interfered with the carbohydrate metabolism of brain cells, it was suggested that a similar action on the heart, liver, and other organs might be responsible for some of the poisonous symptoms of prolonged narcosis. Ström-Olsen³ found that 70 per cent. of patients undergoing this treatment showed acetone in the urine, while glucose tolerance was lowered and glycosuria common. He consequently treated his patients by giving glucose and 10 units of insulin with each 2 c.cm. of somnifaine and reported that extreme drowsiness, cyanosis, coldness of the extremities, and vomiting remained in abeyance; though pyrexia, albuminuria, oliguria, and leucocytosis still occurred, the dangers of prolonged narcosis were in general greatly reduced. Ström-Olsen includes a comprehensive review which it is unnecessary to repeat and says that the average death-rate had been 4 per cent. without insulin, whereas his series of 46 treatments was without a death. Contra-indications are emaciation, cardiac weakness, renal affections, and pulmonary diseases, while tachycardia, a severe fall in blood pressure, high pyrexia, persistent vomiting, and a dusky complexion with shallow breathing and extreme drowsiness are indications for the cessation of treatment.

In a later communication Ström-Olsen and McCowan⁴ report that of 49 schizophrenics 8.1 per cent. recovered and 38.7 per cent. improved; of 45 manic-depressives, 37.7 per cent. recovered and 29 per cent. improved; and of 13 psychoneurotics 61.5 per cent. recovered and 15.4 per cent. improved.

The present report deals with 60 treatments by prolonged narcosis given to 56 female patients between January, 1934, and June, 1935, 45 treatments being carried out with insulin and glucose as well as somni-

faine, and 15 with somnifaine and glucose only. Four patients had two courses of treatment, one each with and without insulin, two being given insulin during the first course and two during the second. There were 3 deaths in the series, 2 while receiving insulin—a death-rate of 5 per cent. Before discussing the toxic effects further, a brief summary of the results will be given.

RESULTS OF TREATMENT: DOSAGE

Psychoneuroses.—Anxiety states, 8 patients. Of these, 4 showed no change; 1 showed slight improvement, but soon relapsed; 1 showed slight improvement which was maintained; and 2 showed marked improvement, which was maintained. Exhaustion states, 2 patients. One showed no change and the other slight improvement which was maintained. One case of hysteria was unaltered by treatment.

Mania (11 patients).—One chronic mania remained unchanged. Of the acute cases 1 died; 3 others all showed immediate benefit but all relapsed. Of these, 2 relapsed quickly and have remained hypomanic for over a year, while the other remained well for a few months, after which an acute relapse was treated by somnifaine narcosis with a very excellent result; the patient has been perfectly well for over a year. The remaining 6 were acute manic types with superadded confusion. Two showed no response, 2 improved but relapsed, and 2 improved in a very striking manner and were discharged from hospital in one and two months respectively.

Melancholia (11 patients).—Of 3 cases of the involuntional type, none showed any response to treatment. One was discharged later. Of the others one died and one showed no change. Three improved but relapsed, and 3 improved considerably and were later discharged; but the duration in hospital was not strikingly reduced.

Schizophrenia (19 patients).—In 8 cases there was no improvement, and 2 of these had a further course, again with no benefit. Three patients improved and were discharged from hospital but later returned. One of these returns had a second course without benefit. Three improved, were discharged, and remain well. One of these was a voluntary patient aged 26, who had been a certified patient at 22 and had been in hospital for two years, afterwards remaining well for nearly two years. When seen at an out-patient clinic she had been away from work for two months with apathy and odd conduct. She was given a 10-day treatment and returned to work a week later.

The last of this group was a chronic patient subject to manic episodes of great intensity and duration. One of these acute phases was treated with marked success, and she was out on parole a few days after the treatment finished.

Paraphrenia (3 patients).—Two menopausal paranoid women, aged 44 and 47, whose prognosis was considered unfavourable, improved in a very remarkable manner. One had been completely stationary for nearly three months but after treatment was discharged in less than a month, while the total duration in hospital of the other was less than two months. A third case, aged 55, improved but soon relapsed.

The last case of this series was a young but chronic epileptic, who had been in a state of continued excitement for two months. A severe toxicosis resulted in death.

Altogether, in 60 treatments, definite improvement was shown 33 times, and in 16 cases it was maintained at least for a considerable period. The average duration of treatment and dosage was as follows:—

	Days.	Dosage per day.
Under 45 with insulin	.. 9.3 5.7 c.cm.
.. 45 without 10.5 5.3 ..
Over 45 with insulin	.. 8.0 4.2 ..
.. 45 without 6.9 6.3 ..

The average dosage is similar to that reported by Ström-Olsen. If cases whose treatment was abandoned after two or three days were excluded, the duration would read appreciably longer.

20 c.cm. of 30 per cent. alcohol hourly for four doses, as recommended by Carrière, Huriez, and Willoguet,⁸ and this produced profuse sweating and a stronger pulse, but failed to delay the end. In the first case recovery took place without lumbar or cisternal puncture, and cisternal puncture was performed once in a fatal case and once in a case that recovered. In all these 6 cases consciousness was restored, but the toxic process in the liver, kidneys, or heart was too advanced for treatment to be successful in 2 of them.

Epileptiform convulsions.—One patient had a convulsive seizure 4 days after the termination of a 12-day course. The narcosis was without incident, and there was no personal or family history of fits.

THE DEATHS

The first death occurred in a case of mania.

The patient, aged 32, developed a temperature of 102° F., with albumin, abundant casts and sugar in the urine on the eleventh day. Treatment was stopped and the patient soon began screaming ceaselessly. Rectal paraldehyde and numerous stimulant drugs were tried but profound exhaustion set in and the patient died on the 13th day with a terminal hyperpyrexia of 107°. Sections of the heart, liver, and kidneys were examined by Dr. J. Gough of Cardiff, who found that the kidneys showed evidence of damage to the epithelium of the convoluted tubules, many of the cells of which showed necrosis and were desquamated. The liver showed cloudy swelling and some small areas of early necrosis.

The second case was of the pneumonic type, referred to above, in an epileptic aged 16. Toxic damage to the liver and kidneys was evident. The third death was also of the pneumonic type. Material from the liver and kidneys was sent to Dr. Gough and careful

examination failed to show any evidence of toxic change. The lungs at autopsy were greatly congested and œdematous but not pneumonic, and since consciousness was restored before death, acute toxic myocarditis was probably present. Unfortunately no microscopic examination of heart muscle was made. The patient was aged 47.

The first fatal case received 80 c.cm. of somnifaine in 11 days, the second 12 c.cm. in 3 days, and the third 38 c.cm. in 6 days.

CONCLUSIONS

Prolonged narcosis often produces definite improvement—sometimes dramatic improvement—in psychotic cases. The use of insulin with glucose is an advance in treatment, but this form of therapy remains dangerous.

I wish to thank Dr. H. B. Leech, superintendent of the Warwickshire and Coventry Mental Hospital, for permission to report these cases, and Miss Ring, of the nursing staff, for her skilful supervision of the nursing details, the importance of which cannot be over-estimated. I am also very grateful to Dr. Gough, of the pathology department of the Welsh National School of Medicine, for his reports on post-mortem material.

CLINICAL AND LABORATORY NOTES

THE IMPERFECTLY MIGRATED TESTIS

SOME STATISTICAL DATA

BY PEARSE WILLIAMS, M.D., M.R.C.P. Lond.

PHYSICIAN TO THE CHILDREN'S HOSPITAL, PADDINGTON GREEN,
AND THE WILLESDEN GENERAL HOSPITAL, LONDON

A RECENT article by Spence and Scowen in THE LANCET¹ has brought out the possibility of success from treating the undescended testicle with gonadotropic hormone. A factor of importance in deciding whether to recommend injection treatment will be, no doubt, the age of the patient. This was brought out by Denis Browne in a subsequent communication.²

In Spence and Scowen's records of 33 boys treated by this method, 25 were under 14 years of age, and I believe that in a good proportion of these the testicle would have descended naturally without hormone therapy. This is not, however, to deny the value and importance of the work of Spence and Scowen in showing us that we have a new and potent means of treating these patients. For some years I have been responsible for the health of boys attending a large secondary day-school in central London and have, in my notes, recorded all cases of undescended testis and noted each year the progress made. The figures obtained are instructive and I record them as a contribution to the subject. They give some indication of the age at which stimulatory treatment should be begun. In studying the figures we must not forget

that a number of boys probably had had undescended testes which had reached the normal position before my first observation.

The records of 2104 boys were examined. Of these, 38 had one testicle undescended (1.8 per cent.); 21 had both testicles undescended (1.0 per cent.). The majority were observed up to the age of 16 and a very few up to the age of 18. The ages at first observation were as follows:—

Age in years.	Cases.	Age in years.	Cases.
8-9	1	12-13	11
9-10	2	13-14	8
10-11	6	14-15	11
11-12	20		

Of 38 boys in whom only one testicle was undescended there was natural descent in 24 (63 per cent.); of 21 boys in whom both testicles were undescended there was natural descent in 14 (67 per cent.). In examining my data however I am able to make further observations and corrections. Ten boys were not seen by me over a sufficient number of years for adequate observation, and six boys fell into the second group of Denis Browne in that the lack of descent was complicated by the presence of a hernia or hernial sac, or operation for such abnormality had already taken place. This leaves 43 boys fully observed, and if the figures are thus revised we find that—

Of 27 boys in whom only one testicle was undescended and no complicating factor was present there was natural descent in 24 (87 per cent.).

Of 16 boys where both testicles were undescended and no complicating factor was present there was natural descent of both in 14 (87 per cent.).

¹ THE LANCET, 1935, ii., 1335.

² Ibid., p. 1484.

The ages at which natural descent occurred were as follows:—

Age in years.	No. of cases.	
	One testicle.	Both testicles.
11-12	2	2
12-13	5	3
13-14	4	1
14-15	7	5
15-16	5	3
16-17	1	1

I have not analysed specifically the age of descent of each testis in the bilateral cases, but from my records can state that up to two years may elapse before one testis follows the other into the scrotum, or one may descend and the other fail to descend. Can we infer therefore that some other factor is present other than a lack of gonadotropic hormone?

I feel justified in concluding from my observations that treatment is not required in these cases until puberty is well advanced, and that up to the age of 16 natural descent is probable. We do not know as yet the full implication of injecting powerful hormones into the growing boy, and I believe it will be wise to refrain from advising their use except from the experimental standpoint until it appears evident that at a reasonable age—e.g., 16 years—natural descent is not occurring. Those boys in whom a complicating factor is present require the advice of a surgeon as soon as the abnormality is discovered.

GADGETS IN PLASTER WORK

By W. GRANT WAUGH, M.D., F.R.C.S. Edin.

SURGEON TO THE MONKWEARMOUTH AND SOUTHWICK HOSPITAL; ASSISTANT SURGEON TO THE ROYAL INFIRMARY, SUNDERLAND

THE use of plaster-of-Paris is becoming rapidly more widespread in this country with the adoption of Böhler's methods and the introduction of the standard Cellona bandage. The removal of the plaster cast at the end of the appropriate period, however, still entails the waste of much muscular effort, time, and temper, usually on the part of some unfortunate ward nurse. Patients with fracture themselves say that removing the cast is the most painful part of the Böhler technique. I have used this treatment for the last six years, after a course of study in Vienna, and it may be of service to describe a few methods which, in my experience, make the manipulation of a plaster cast less of an ordeal to both parties.

FIG. 1.—The hinged lid.

1. *Cutting a window.*—A window in the plaster is often necessary, for example when compound fracture has been closed by operation, and it is easily cut out if the wound is covered by the lid from a cocoa or other tin and the plaster applied over it. The lid and overlying plaster are excised before the latter has set and the free edges pressed in. A brass lid with a rolled edge, and hinged in the centre to fit the contour of the limb, has been made for me by the Medical Supply Association (Fig. 1).

2. *Cutting instruments.*—In addition to the usual plaster scissors, two curved cobbler's knives, with external and internal cutting edges respectively,

are serviceable, while the discarded scalpel from the theatre is indispensable; but let me utter a warning against the use of the Bard-Parker type, the blade of which is too fragile and may break and lacerate the operator's fingers. The gadget known as the "jigger knife," which carries the Gillette type of razor blade, is, however, safe and very useful; the blades are

FIG. 2.—The pins.—(a) The head of the left-hand member from the left, and (b) from the right. (c) The tapering end to fit the fixing plate. (d) The heads interlocked; anterior view and (e) posterior view. (f) The fixing plate.

The pins with the fixing plate attached are bent roughly to the shape of the limb and foot, and the plaster is applied over them. When the plaster is drying it is split down the groove between the pins, which are disengaged and lifted out. The pins are made from brass wire (No. 8 S.W.G.), the heads from 1 in. round brass (size of each, 1/4 x 1/4 in.). The pins are conveniently 2 ft. long. The plate is of brass (No. 16 Imp. W.G.), and the tubes loosely fit the ends of the pins. The whole instrument is hand soldered.

sharp and the supply of ammunition is unlimited. The small electrically driven circular saw of German origin is an ideal cutting instrument—apart from the expense. Fretsaw blades are too brittle and usually too short, but the old-fashioned bow saw, with a 1/16 in. blade and 18-24 in. long, can often be used to remove old casts. The blade, covered with a soft metal guard, is "wangled" between the limb and the cast, the bow attached to the ends, and the cast is sawn diagonally outwards.

3. *Splitting the plaster.*—"In every case where a plaster cast is applied before the swelling has disappeared, the cast should be split directly after its application."¹ This is often necessary, and to simplify it I have placed two metal knitting needles on the fleshy part of the limb, bending them to fit the curves and plastering over them; the drying plaster is then cut down the ridge between the pins. As knitting needles of suitable length and calibre are not readily obtainable I have elaborated these into an instrument, the details of which are illustrated (Fig. 2). The pins are 2 ft. long, with interlocking heads, and a slot into which the lower ends fit to prevent spreading. These pins I find of great help, and I use them as a routine in every cast application. They render the splitting of a plaster a rapid and safe procedure.

I am indebted to the Medical Supply Association, who first made a set of Böhler's equipment for me in 1930, for the skill with which they have interpreted these ideas.

A CASE OF HÆMOPHILIA TREATED WITH RUSSELL VIPER VENOM

BY GEOFFREY A. BAKER, M.B. Durh.

HOUSE PHYSICIAN AT THE TORBAY HOSPITAL, TORQUAY

AND

PAUL C. GIBSON, M.D., M.R.C.P. Lond.

PHYSICIAN TO THE HOSPITAL

THE patient, aged 11, a fat boy with a fair complexion, was admitted to the Torbay Hospital on Oct. 11th, 1935. He has one brother who is said to be hæmophilic and two sisters who are healthy; no family history of blood disease could be obtained from either of his parents. He had been bleeding for ten days from the gum round an upper incisor tooth.

On admission he was collapsed and pale. His mouth was in a septic condition, the gums were inflamed, and he had several carious teeth. A blood examination showed: red cells 4,020,000 per c.mm.; hæmoglobin, 45 per cent.; platelets, 500,000; bleeding time, 3½ min.; coagulation time, 7½ min. No other physical signs were noted.

With an acriflavine mouth-wash (1 in 1000) the gums improved and the bleeding stopped, but it recurred a few days later; and permanent improvement seemed unlikely until the tooth was removed. This and an adjacent tooth were extracted on Nov. 23rd under local anaesthesia. There was no serious bleeding for about eight hours; oozing then began and continued steadily in spite of plugging with, alternately, adrenaline, turpentine, and tannic acid. The blood collected in the receiver was clotted, but the clot was soft and friable. On Oct. 24th a blood transfusion of 200 c.cm. was given, his father acting as donor. Difficulty arose from the fact that the boy's veins were obscured by subcutaneous fat, except in the neighbourhood of the wrist. An attempt to get into one of these veins with a needle failed and so an incision was made just above the wrist. The vein was found to be too small to admit even the smallest cannula, and another incision was made in the antecubital space and the transfusion effected. Both wounds were firmly sutured and a pad tightly applied. In spite of this, oozing began from both incisions; there were now, therefore, three oozing points instead of one. He became steadily exsanguinated, but, owing to the impossibility of getting blood into his vein without making another incision, further transfusion was impracticable.

On Oct. 26th we decided to try to obtain some snake venom. We wired to a firm in London, confirming the order later by telephone, when we were informed that the order would be executed immediately. At midnight a package arrived, but to our dismay it was found to contain a supply of antivenin. By this time the boy's condition was getting desperate. At 9.15 the following morning we telephoned to the pharmacist of St. Bartholomew's Hospital for help. He most kindly undertook to see if any venom could be obtained, and, if not, to send some of their own supply. At 10 a.m. a telegram arrived from Messrs. Burroughs Wellcome and Co. saying that some Russell viper venom, which had been supplied from the experimental stock at the Wellcome Physiological Research Laboratories, Beckenham, Kent, was being put on to the 10.30 train for Torquay. It arrived at 2.30 p.m. and was applied immediately. From that moment we had no further anxiety. Bleeding stopped at all three points and did not recur to any serious extent. The venom was applied, soaked in plugs of gauze, in a dilution of 1 in 10,000; to ensure proper access the stitches were removed from the two wounds in the arm. During the first 24 hours the venom was frequently reapplied and at first there was some slight oozing from the incisions. I think this was because the only way of stopping the bleeding before the arrival of the venom was

by applying continuous pressure, enough to obstruct the circulation; when pressure was released there was considerable hyperæmia for a time. In the tooth sockets, immediately after the venom was applied, a firm elastic clot formed. The wounds healed by granulation in about three weeks.

On Jan. 20th, 1936, some bleeding started round the left lower canine. The tooth was extracted and the socket plugged with venom. There was some slight oozing but this was never serious, and it had completely stopped by Jan. 23rd. He was discharged from hospital on Feb. 3rd.

Special points of interest are: (1) The immediate hæmostasis in the tooth socket. (2) The effectiveness at a site where application was not easily sustained; the tooth socket was shallow and could not be packed very efficiently. (3) The firmness of the clot; this was particularly noticeable in the socket, where the clot felt to be of the consistency of rubber. (4) The complete absence of any undesirable effects, although a considerable amount of the venom had to be used on the arms.

All these satisfactory effects could be expected from the published results of Macfarlane and Barnett,¹ to whom medicine owes this valuable remedy.

We would express our most sincere thanks to the pharmacist of St. Bartholomew's and to the director of the Wellcome Physiological Research Laboratories for the promptness with which they came to our help.

AN UNUSUAL TERMINATION OF CIRRHOTIC SPLENOMEGALY

BY J. F. PATERSON, M.R.C.S. Eng.

CASUALTY HOUSE PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL

SPONTANEOUS rupture of the splenic pedicle is so unusual that the following case is reported even though no elaborate investigations were made.

The patient, a man aged 27, was riding a motor-cycle, when he was seized with a sudden attack of upper abdominal pain, felt faint, and dismounted. He vomited his previous meal. He was seen by a doctor at the roadside who diagnosed a perforated peptic ulcer and had him taken to the Norfolk and Norwich Hospital. On examination there he was found to be severely shocked and pale. The temperature was subnormal and the pulse rapid. The abdomen was not rigid, but was generally tender and doughy. The spleen was easily palpable and was firm and smooth. There was dullness in the flanks, but the anterior area of liver dullness was diminished. There were no enlarged veins on the abdomen and the superficial lymph glands were not palpable and he was not jaundiced. Intra-abdominal hæmorrhage was diagnosed and the patient died shortly after admission.

Past history.—At the age of 5 he was in hospital complaining of languor and drowsiness. The cervical, axillary, inguinal, and right iliac lymph glands were enlarged, painless, fairly soft, movable, and discrete. The spleen was enlarged down to the umbilicus and the liver was palpable ½ in. below the costal margin with a regular and smooth surface. Blood examination showed hæmoglobin 60 per cent. and a leucocytosis of 16,000. No differential count was done. He stayed in hospital for three months during which time he developed chicken-pox, and on discharge the spleen had apparently decreased in size. He remained apparently well until a few months

¹ Macfarlane, R. G., and Barnett, B.: THE LANCET, 1934, ii., 935.

before his death when he began to complain of vague upper abdominal discomfort. He was stated always to be pale and yellowish.

At autopsy a large quantity of blood lay free in the peritoneal cavity. There had also been a massive hæmorrhage into the retroperitoneal tissues, which had apparently come from the pedicle of the spleen and blood had burrowed under the splenic capsule. The capsule was not ruptured and the splenic artery appeared normal. The spleen was diffusely enlarged and weighed 42 oz. The liver was greatly shrunken

and weighed only 30 oz.; it showed advanced cirrhosis of the hob-nail type. The other organs appeared normal. The lymph glands were not enlarged and there was no evidence of external compression or thrombosis of the portal vein. It was concluded that the hæmorrhage was the result of spontaneous rupture of one of the veins in the pedicle of the enlarged spleen.

My thanks are due to Mr. J. M. Ridley Thomas and Dr. G. P. C. Claridge for their permission to publish the case.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF PSYCHIATRY

At a meeting of this section held on Feb. 11th the chair was taken by Dr. H. J. NORMAN, the president. Dr. E. T. C. SLATER read a paper on the

Inheritance of Manic-Depressive Insanity

Reviewing the history of work in this field, he mentioned E. Rüdin's studies on the siblings of manic depressives, as yet unpublished, and Hoffmann's work on the children of manic depressives, which still remained the basis of much that was taught and written on the subject. Hoffmann had found the enormous incidence of 30 to 60 per cent. of manic depressives among the children of victims of this form of insanity. His work was open to criticism, largely because of the impossibility of knowing what criteria of diagnosis had been used. Hoffmann had regarded cyclothymia and hypomanic and depressive temperaments, even including "quiet humorists," as tainted with manic-depressive heredity, taking an extreme Kretschmerian attitude. His figures were swelled by a tendency to exaggerate normals into abnormals, and abnormals into lunatics. The only other work of importance was that of Banse on the cousins of manic depressives. The value of his work was limited by the large use made of records. Among 1586 cousins he had found between $2\frac{1}{2}$ and $3\frac{1}{2}$ per cent. manic depressives, $1\frac{1}{2}$ per cent. cycloid psychopaths, and 5 per cent. persons likely to carry the hereditary factor. Dr. Slater said that his own research had been done in the same institute and on the same sort of material as Rüdin's and Hoffmann's. He had selected only cases showing some degree of phasic recurrence; at least one clear manic and one depressive attack, or at least three separate depressive or manic illnesses starting before the age of 50. The Kraepelin diagnosis had been taken, concentrating on the course rather than the symptoms. A surprising feature had been the number of schizophrenics among the children. The figures had been corrected to allow for the factor of increasing incidence of the illness with increasing age. Those under the age of 20 were neglected as having yet had no opportunity of developing psychosis, and those between 20 and 50 were reckoned as half. The results showed an incidence of 15 to 20 per cent. of manic-depressive insanity among parents and children of manic depressives. The higher percentage was obtained if a number of cycloid children were included; these might or might not prove to be manic depressive in later life.

The inadequacy of the material, and the difficulties of ascertainment and of obtaining irreproachable statistics had prevented authors from putting for-

ward theories of the genetic basis of manic-depressive insanity. Hoffmann had suggested the existence of three independent factors each carrying different weights, a total weight being required to precipitate psychosis while a lesser weight made the patient a cycloid or cyclothymic. Rosanoff, Handy, and Plessett proposed two independent factors: a cyclothymic autosomal factor and an activating factor in the X-chromosome, both dominant. Rüdin proposed one autosomal dominant and two autosomal recessives. Luxenburger favoured a theory involving one recessive and one dominant.

These theories were quite premature and served no useful purpose. One thing was more or less certainly established: that the psychosis was inheritable and that the inheritance followed a dominant type. The simplest possible theory depended on a single dominant autosomal gene. Until this theory was shown to be inadequate, no other could be even provisionally accepted. On this theory the expectation of manic depressives among parents, siblings, and children of manic depressives would be 50 per cent. All investigations, however, showed a much lower figure. The reasons for the discrepancy were many. A study of manic-depressive twins had shown that only about 70 per cent. of the uniovular twins developed the illness; this gave a direct measure of the influence of environment, expressed as 30 per cent. The expectation among nearer blood relatives was thereby reduced from 50 per cent. to 25 per cent. Another factor was inadequacy of investigation, probably involving considerable failure of ascertainment; another was the genotypic milieu. The genes had to work, not only in an external environment, but also in an internal environment made up by all the other genes which constituted the hereditary structure. In uniovular twins this milieu was the same for both. Genes, moreover, varied in their manifestations, some requiring quite special circumstances for a hundred per cent. influence. The degree of manifestation bore no relation to dominance, and weakly manifesting dominant genes were very common. Probably in manic-depressive insanity the investigator was dealing with a weak dominant gene that manifested itself in only a proportion of its carriers. The psychosis would not appear unless there were present all the genetic factors necessary to allow a hundred per cent. manifestation of the manic-depressive gene. There was also the external environment, the influence of which was illustrated by the greater incidence in women. The great symptomatic variability would be partly caused by the inclusion of what were not really manic-depressive psychoses. No other possible theory would give anything like this same percentage of manic depressives among parents, siblings, and children; it also fitted in with Banse's $3\frac{1}{2}$ per cent. for cousins—i.e.,

just about a quarter of the empirical expectation for the others. Possibly more than one genetic factor could bring about manic-depressive insanity; this was known to be true for other inheritable abnormalities.

A number of observations pointed to a special relation between manic-depressive insanity and schizophrenia, and the relationship could not be altogether explained away on grounds of mistaken diagnosis. In 10 out of the 15 cases where manic-depressive subjects had been found by Dr. Slater to have schizophrenic children, he had been unable to find schizophrenia in other members of the patient's family or in that of the husband or wife. Another curious thing was that manic depressives were scarcer than might be expected among the relatives of schizophrenics, so that the correlation was in one direction only. Manic-depressive insanity did not stand alone in this peculiar relationship to schizophrenia; the relatives of general paralytics and epileptics also showed an increased incidence of schizophrenia. It did not seem likely or desirable to assume that there were common factors in each and all of these cases. Probably a number of genetically different conditions were included under the term "schizophrenia," but in the great majority of cases it was a destructive process affecting the whole personality. It seemed possible that the gene or genes responsible for the development of the schizophrenia would find it easier to manifest themselves in a genetic milieu which included other hereditary factors predisposing to psychic disorder, whether those other factors had actually manifested themselves or not. There was in genetics no very hard-and-fast line between dominance and recessivity. It was quite possible that the presence of a manic-depressive gene might lend the schizophrenic gene a semi-dominance. Some process like this might be responsible for the strange atypical psychoses halfway between manic-depressive insanity and schizophrenia. If the manic-depressive gene had an activating influence on the schizophrenic gene, the majority of the schizophrenic children of manic-depressives ought to be, so to speak, masked manic depressives. In one family where this point had been studied, a woman had a perfectly typical recurrent manic-depressive psychosis; her mother at the age of 34 had had an acute illness with many manic features which had passed on into chronic hallucinosis with many paranoid ideas, and finally into a chronic schizophrenic state in which she had remained until her death at the age of 79. Her mother, the patient's grandmother, had been four times in a mental hospital with recurrent melancholia, and her mother, the great-grandmother, had had one or more psychotic illnesses. Here were four generations showing a typical dominant inheritance with a schizophrene suddenly appearing in the middle but capable herself of continuing the manic-depressive line. Such facts as there were seemed to indicate that there was not an indefinite series of gradations between the normal and the psychotic. If English psychiatrists adopted the view that there was such a gradation, they should be clear about their grounds for doing so.

DISCUSSION

The PRESIDENT said that he saw scope for increased knowledge of the transmissibility of the manic-depressive psychoses in the daily work of psychiatrists, particularly when they were considering the marriage of their patients. Interesting studies could possibly be obtained from historical records of royal houses,

the conduct of whose members was largely public and whose record of intermarriage was clear. The emperor Nero was a case in point: his uncle Caligula had been insane; Drusus, another uncle, had been epileptic; his grandfather had been a man of great arrogance, prodigality, and cruelty; his father had been brutal and reckless of the lives of others; and his mother, Agrippina, had been a prodigy of immorality. Nero himself had been epileptic and had committed suicide in the early thirties.

Dr. AUBREY LEWIS regarded Dr. Slater's paper as the most important contribution to the subject that had yet been made. It was difficult to regard manic-depressive illnesses as accounted for in any single way, whether by a single dominant factor or otherwise. In a certain series he had found that children with one manic-depressive parent had shown a large percentage of cyclothymic and manic-depressive conditions, whereas children of two manic-depressive parents had shown nothing. It was not impossible that a dominant was sometimes present and sometimes not. Whether there was a recessivity was another matter. He had not been entirely convinced by Dr. Slater's reasoning about the relationship between the schizophrenia occurring in the families—the ascendants or descendants—of manic depressives, and the manic-depressive conditions occurring in the propositi. It was useful to consider Kahn's view that the important factor was not so much the presence of schizophrenia as the kind of schizophrenia. If it were the recurrent kind, one might be dealing with a factor common to both conditions which was responsible for periodicity and recoverability, and this factor might be found in schizophrenic strains also.

Dr. C. P. BLACKER hoped that the paper would be regarded by the genetic historians of the future as a piece of pioneer English research. Dr. Slater's hypothesis of a genotypic dominant which was prevented from manifesting itself as a phenotypic dominant through various intrachromosomal, environmental, and physiological factors was ingenious. It was, he thought, difficult to obtain any precise information concerning the genotypic milieu, but some evidence might be forthcoming about the environmental milieu. He asked whether Rosanoff or anybody else had been able to point towards an environmental factor which might have operated in those cases in such a way as to bring out the latent genotypic disposition in one pair of twins as against the other pair—i.e., whether the manifestation of the disease in the affected twin was in any way traceable to environmental strain, shock, or episode. He also asked whether Dr. Slater had been led to suppose that the indubitable cases belonged more to the pyknic type of bodily formation which Kretschmer had stated to characterise manic-depressive persons.

Dr. T. A. MUNRO said that it was possible to get surprisingly accurate information about families in rural areas, provided that one asked at least two and preferably three informants. Country people were anxious to give information about their relatives, and pleased to think that attention was being paid to the insane person in the mental hospital.

Dr. MEYER-GROSS saw more hope than Dr. Lewis and Dr. Blacker of an ultimate explanation of the meaning of the genic milieu. This was not only an interior milieu but might manifest itself in various ways. The different components of the character might one day show the milieu which existed in a single person or a number of persons, so that it

could be judged according to the character components. It might then be possible to say something about the influence of the genic milieu upon the special gene which was being sought.

Dr. H. CRICHTON-MILLER stated that he had recommended a colleague, who had contemplated marriage with a lady whose heredity was suspected of a manic-depressive taint, to read "Chances of Morbid Inheritance." From Dr. Slater's paper it appeared that all the data in this book were founded on erroneous statistics. That was the kind of experience which clinicians had when they came to scientific meetings. The moral was obvious: they should keep away.

Dr. C. W. J. BRASHER considered that statistics could only be valuable if carefully corroborated by personal interviews and clinical experience.

Dr. SLATER denied any implication that he wished to destroy the standing of Hoffmann or anyone else. The great fault of Hoffmann's work had been that he was so Kretschmerian; he would take people of a more or less cyclothymic character and say that they had a manic-depressive taint; this, though possibly correct, was premature. Dr. Slater had found his manic depressives definitely above the social level of their population. Manic depressives tended to be somewhat more pyknic than other people. German workers had frequently neglected the influence of environment, but he doubted whether any information would be forthcoming in the near future on what special environmental factors had an effect on the illness.

SECTION OF MEDICINE

At a meeting of this section held on Feb. 18th the chair was taken by Sir CHARLTON BRISCOE, the president.

Dr. OTTO LEYTON opened a discussion on the morbid conditions which cause

Progressive Hyperglycæmic Glycosuria

and the circumstances which modify its course. Several organs in addition to the pancreas, he said, were involved in impairment of carbohydrate metabolism; hyperglycæmia might be caused by over-activity of the adrenal glands brought about by anxiety, or hypertrophy associated with basophil tumour of the anterior pituitary. Dogs could survive removal of the pancreas if the nerves of the adrenal glands were cut or the pituitary gland removed. Insulin seemed to need something to activate it; an appreciable quantity of insulin might be found in the pancreas of a patient dead from diabetes. If the blood of one animal, A, were led to the brain of another animal, B, and the blood from the pancreas of B conducted to a depancreatized animal, C, B's head being connected to its body only by the vagus nerve, it had been shown that when sugar was added to the blood of A the blood from B to C contained insulin. The complementary experiment showed that injection of insulin into A caused a rise of sugar in the depancreatized C. Some stimulus therefore passed down the vagi to the pancreas. The brain centre which could stimulate the production of insulin could also perhaps inhibit it. Section of the splanchnic nerves seemed to make the body more sensitive to insulin. Sodium chloride might to some extent replace cortical extract in Addison's disease and insulin in diabetes mellitus. Occasionally a case of basophilism lost glycosuria after deep irradiation of the pituitary gland. The posterior lobe of the pituitary also elaborated a

substance which neutralised insulin. Trauma as well as tumours might lead to hyperglycæmia. The thyroid encouraged glycogenolysis, and therefore hyperglycæmia, as long as there was glycogen in the liver.

The question arose whether insulin was essential to the metabolism of carbohydrate. There might, weight for weight, be more insulin in the kidney than in the pancreas of a healthy animal. The experiments reviewed, said Dr. Leyton, suggested that insulin was not essential, or that other cells than those in the pancreas could make insulin. Pancreatic cells were very sensitive to toxins, including those of the common cold, and to over-stimulation. The essential treatment of diabetes, it was now recognised, was to rest the pancreas and give it a chance of rejuvenating. Amelioration was most probable if the sugar content of the patient was kept low. Little success had been obtained from pancreatropic hormone, but cure had been ascribed to pancrealytic serum. A very small number of cases were benefited by irradiation of the pituitary. Partial thyroidectomy and section of the splanchnic nerves might reduce the number of doses of insulin, but did not modify the course of the disease. The number of injections required could be reduced by giving a suspension of insulin in castor oil, or protamine insulinate. Both preparations had a delayed effect. They would, however, only act in certain cases. Reduction in dosage of insulin might also be possible with a glucose diet.

THE CONTRIBUTION OF THE "SOIL"

Dr. J. GRAHAM WILLMORE stressed the necessity for some constitutional fault in the individual to sensitise the soil for the seed. As observed among war pensioners, the "causes" of diabetes seemed to be: mental stress, resulting in chronic progressive endocrine imbalance; retained bits of metal or dead bone in old gunshot wounds with recurrent flares; unbalanced diet, especially excess of fat; arterial degeneration with good living; and hæmochromatosis. In some cases stimulation of the adrenals through the sympathetic nervous system and thyroid caused excessive glycogenolysis, with which the pancreas strove to deal by increased production of insulin. Chronic overwork caused eventual breakdown. The diabetic pensioners all had good war records of constant "front line" work. Gunshot wounds around the pituitary caused endocrine imbalance, but these patients responded to insulin as well as others did, provided there was no intercurrent sepsis to neutralise the effects of insulin. Possibly the pituitary secreted a hormone which acted as a brake on the pancreas; this might be absent in obese young people, and overwork of the pancreas ultimately ended in diabetes. The patients whose old wounds flared up now and again for no obvious reason had a different bacteriology every time. Not infrequently the flare-up was followed by heavy glycosuria and ketonuria requiring temporary or permanent administration of insulin. The blood-sugar must be kept low, under frequent control investigations, and to do this all sepsis must be eradicated. The sugar was more easily controlled if the patient received the first dose of insulin on awaking from sleep, instead of after a little activity. In the diabetic the liver did not seem to know when to stop in producing the glycogenolysis needed for the transition from sleep to waking.

DIFFERENTIAL DIAGNOSIS AND PROGNOSIS

Dr. H. P. HIMSWORTH observed that "progressive hyperglycæmia" had never been observed clinically

or experimentally; he presumed that it meant hyperglycæmia progressing beyond normal limits. If there were several conditions producing "diabetes" there must be varying prognosis and treatment. It was already possible to distinguish certain clinical types of hyperglycæmia which were not diabetes mellitus. It was impossible at the acute stage to distinguish between cellulitis causing glycosuria and mild diabetes complicated by cellulitis. Many cases of hyperthyroidism had difficulty in dealing with sugar. If a patient was mistakenly given a diabetic diet and insulin, not being really diabetic, his blood-sugar might show a suspiciously "diabetic" curve. On an ordinary diet he would show normal curves. It was unsafe to assume that a person took a normal amount of carbohydrate by choice; healthy people rarely took above 300 g. of carbohydrate a day and many people only took 100 g. An increase of carbohydrate often abolished post-prandial glycosuria. Such cases of mistaken diagnosis accounted for reports of the cure of diabetes. If they were given insulin the sugar-tolerance curve was made very much worse. The curve was high in most cases of spontaneous hypoglycæmia. A person who tolerated large doses of insulin was not necessarily a diabetic.

Dr. T. C. HUNT mentioned the prognosis of hyperglycæmic glycosuria as seen in a number of untreated and treated adult cases. Of the untreated, about a third got better and only a half got worse. Of treated cases about 30 per cent. got worse. The factors affecting prognosis might be found in causation or course. Of the improved cases only a few were overweight or neuropathic, and nearly 70 per cent. were over 50 years of age. Of those who did not improve, a third were overweight, a half were neuropathic, and the majority were under 50. If the glycosuria were noticed in the course of an infection

the outlook was usually good; if it were noticed during mental shock, the patient seemed not to do so well. An onset associated with dyspepsia was found in some cases; biliary drainage in two of these had revealed an associated external pancreatic disorder, but, on the whole, stimulation of the external secretion did not affect the internal secretion.

DISCUSSION

Dr. RONALD JONES described experiments he had done on pituitary hyperplasia in hyperglycæmia, which he did not regard as significant. Injection of extracts produced no change in the blood-sugar of dogs or patients. There seemed in fact to be no such thing as a pancreatropic hormone.

Dr. E. P. POULTON asked for details of the patients subjected to deep pituitary irradiation, and observed that Joslin had examined severely shocked men coming back from the front line and had never found glycosuria. Perhaps people reduced their carbohydrate because there was a pernicious doctrine going about that carbohydrates were no good.

Dr. LEXTON recalled a fat patient who used to develop hypoglycæmia when normal saline was injected. Some people had very poor power of storing carbohydrate throughout their lives, and the title had been chosen to exclude these stationary hyperglycæmias. The sugar-tolerance test had been abandoned by him as a diagnostic measure, except for purposes of exclusion. X ray therapy had only been used in cases of basophilism.

Dr. WILLMORE observed that his pensioners had all been normal before the war and had developed diabetes during or soon after it.

Dr. HIMSWORTH said that all over the world since 1900 there had been a progressive change in diet, in the direction of decrease of carbohydrate and increase of fat.

REVIEWS AND NOTICES OF BOOKS

Treatment of Acute Poisoning

BY H. L. MARRIOTT, M.D., M.R.C.P. Lond.,
Resident Medical Officer, Middlesex Hospital;
Assistant Physician, Miller General Hospital,
Greenwich. London: Published for the Middlesex
Hospital Press by John Murray. 1935. Pp. 45. 5s.

The idea of treating a case of acute poisoning conjures up for most of us nightmares of stomach-pumps, of long lists of poisons and their antidotes, of home-made emetics and antidotes, and of the indications and contra-indications of gastric lavage. It is curious that such anachronisms as are embodied in the standard accounts of this important branch of medicine have apparently satisfied the inquirer for many decades, especially when it is realised that for long carbon monoxide has held pride of place among the causes of accidental or suicidal poisoning, at any rate in this country and in America.

Dr. Marriott in this monograph strikes at the roots of the worn-out doctrines repeated from text-book to text-book and builds a new and rational concept based on the treatment of several hundred patients at the Middlesex Hospital. He has assumed reasonably enough that even if the identity of the poison is known, the antidote is either not remembered or is not at hand. The principles underlying the

successful treatment of acute poisoning are found in the three questions which the medical attendant should put to himself in every case: Is the patient asphyxiated or suffering from poisoning by a gas? If the poison was not gaseous, how did it enter the body? Is life endangered by coma, dehydration or dechloridation, pain, or delirium, and convulsions? It is a measure of the success of Dr. Marriott's elucidation of these matters that the substance of his principles could be condensed into small compass, for of all branches of medicine, this is one in which the physician is called to deal with a desperate emergency with little time to think and even less to look up references. But here is not merely a reconstruction of indications; there is supplied, with chapter and verse, the exact technique of the various procedures to be used by the physician. Furthermore, the author has devised a new method of gastric lavage which if adopted as a routine should save many a patient recovered from his poison from death through broncho-pneumonia. Medicine is already indebted to Dr. Marriott and his collaborator, Dr. A. Kekwick, for the method of blood transfusion by the drip method which he published in our columns last year (*THE LANCET*, 1935, i., 977) and which has rapidly gained general recognition as the method of choice in suitable cases. We now have to thank him for a work which reduces to order and reason a section of medicine hitherto disorderly and irrational. This manual is a landmark in the literature of the therapeutics of poisoning.

Diseases of the Chest

By J. ARTHUR MYERS, M.D., Professor of Medicine, Preventive Medicine, and Public Health, Minnesota Medical School. New York: National Medical Book Co. Inc. London: H. K. Lewis and Co. Ltd. 1935. Pp. 385. 13s. 6d.

A GENERATION ago tuberculous infection was considered to be almost universal by the time adult years were reached, and a positive tuberculin reaction was only considered important in quite young children. Prof. Myers takes up an entirely different position. He argues that as the dangerous reinfection type of tuberculosis can only occur after the tissues have been altered by the primary infection, all positive reactors should be kept under careful observation. In such cases an X ray film of the chest should be made at least every year and preferably every six months on persons after the age of 10 years. Heimbeck's observation that amongst young nurses it is mainly those who have escaped a childhood infection who became ill with pulmonary tuberculosis does not fit in with Prof. Myers's theory, and it is a pity that this work is not even referred to. Until more definite evidence is brought forward to show that tuberculous disease is *less* prone to affect those who escape childhood infections, the expenditure of the very large sums of money, which would be required to keep some millions of healthy positive reactors under medical supervision, does not seem justifiable. The remainder of the first section of the book deals with the physical signs and symptoms and treatment of pulmonary tuberculosis; the advantages of early treatment by artificial pneumothorax are stressed and the indications for the various procedures of thoracic surgery are clearly given.

Non-tuberculous diseases of the chest are the subject of the second part of the book. Both serum treatment and artificial pneumothorax receive favourable mention in the treatment of lobar pneumonia; in the latter procedure not more than 200 to 300 c.cm. of air should be introduced at a time; two or more refills may be necessary at intervals of 12 to 24 hours.

In the discussion of the treatment of bronchiectasis, empyema, and pulmonary abscess, conservative measures are first described, but the indications for surgical intervention are also given and a brief account of the methods used. Diseases due to mould-like bacteria, true moulds, and yeast-like fungi are dealt with in a short but adequate chapter illustrated by several skiagrams of these rare diseases. The concluding chapter on diseases due to inhalation of dust brings into association such ill-assorted conditions as hay-fever and silicosis. The book is well illustrated and has a full index as well as a bibliography, mainly American, at the end of each chapter.

Painful and Dangerous Diseases of the Ear

By R. R. WOODS, M.B., F.R.C.S.I., Surgeon in Charge of the Ear, Nose, and Throat Department, Sir Patrick Dun's Hospital, Dublin. London: Humphrey Milford, Oxford University Press. 1936. Pp. 188. 15s.

A DIFFICULTY which confronts the specialist in a teaching hospital is to decide how best to impart a useful knowledge of his subject to the future prac-

itioner. If he attempts to cover the whole of the speciality in the limited time available, the instruction is likely to be superficial and allows far little discrimination between matters of clinical importance and those with which the general practitioner is rarely concerned.

Mr. Woods has written this book to fill the gap between the larger manuals of otology, which contain much material of interest only to the specialist, and the student's handbooks, which tend to treat essential subjects with insufficient detail. He has fulfilled his intention most admirably, and has produced a lucid account of the common forms of suppurative disease of the ear, for his plan amounts essentially to a description of these affections. We could have wished, however, that more consideration had been given to the important point of when to operate in acute mastoiditis. Mr. Woods does say that "it is inadvisable to operate on a case of mastoidism, for the course of the disease after operation may be stormy," but he fails to emphasise the fact that operation for acute mastoiditis is rarely necessary in the first week or ten days from the beginning of the otitis, that a proportion of these cases recover without operation, and that the course after over-early operation is likely to be tempestuous. We have seldom read a clearer exposition of the intracranial complications of aural disease, while the short final chapter on the cerebro-spinal fluid is most valuable. It is wise to have made no attempt to describe details of the major operations, but an account of their after-treatment would have been helpful. There are some good illustrations in the text, and 24 coloured pictures showing the otoscopic appearances of various conditions of the drum.

We recommend this book to the practitioner who wishes to gain a sound knowledge of the more important forms of aural disease that he is likely to encounter.

1935 Year Book of the Eye, Ear, Nose, and Throat

By E. V. Z. BROWN, M.D., Professor of Ophthalmology, and LOUIS BOTHEMAN, M.D., Assistant Professor, University of Chicago; GEORGE E. SHAMBAUGH, M.D., Clinical Professor Emeritus; ELMER W. HAGENS, M.D., Assistant Clinical Professor; and GEORGE E. SHAMBAUGH, Jr., M.D., Clinical Instructor of Otolaryngology, Rush Medical College of the University of Chicago. Chicago: The Year Book Publishers; London: H. K. Lewis and Co., Ltd. Pp. 638. 10s. 6d.

THIS issue of the Year Book, which consists as usual of abstracts from the current literature, discloses this year no notable advances or striking new methods but gives evidence of great activity in the exploration of the fields covered by these specialties, and particularly of research into the intricate physiology of both the hearing and balancing functions of the labyrinth. The abstracts are well chosen and well written and, as in former years, shrewd editorial comments on the more important of these add to their value. The editors plainly show their dislike of early operation in acute mastoiditis. They quote statistics from an article in an English journal of 91 cases, in 73 of which the duration of the otitis media varied from two to eight days; of these cases five died from meningitis, one developed suppurative parophthalmia, and the average time of complete healing with a dry ear was ten weeks; and they very

properly point out that these figures would be very much improved if operation were delayed, when the duration to complete healing is normally about three weeks. This is a convincing argument against early operation in acute otitis, but we believe that the editors are not correct in thinking that early operation is practised frequently in England. A number of articles dealing with malignant disease of the throat and its treatment by surgery, diathermy, and radiation are summarised, and are a useful guide to the present position of the treatment of these conditions. Indeed, the Year Book, with its very full index, is a most valuable book of reference to the newest work.

1. Commoner Diseases of the Skin

By S. WILLIAM BECKER, M.S., M.D., Associate Professor of Dermatology in the University of Chicago. New York: National Medical Book Co. Inc.; London: H. K. Lewis and Co., Ltd. 1935. Pp. 283. 13s. 6d.

2. Common Skin Diseases

Third edition. By A. C. ROXBURGH, M.D., F.R.C.P., Physician in charge of the Skin Department, and Lecturer on Diseases of the Skin, St. Bartholomew's Hospital. London: H. K. Lewis. 1935. Pp. 377. 15s.

1. THE claim advanced by the author that "intensive study of functional diseases in all fields of medicine has tended to clarify and simplify the study of dermatology," does not solve or appreciably lighten the many problems of the therapist, although it opens up new avenues for research.

This is not a book for beginners. A knowledge of histology is presumed, for no microscopic appearances, even of the fungi, are portrayed. A discursive style is adopted throughout, headings and sub-headings are avoided, and the aim appears to be to interest rather than instruct. The subject matter is considered in 26 chapters. The first is given to the care of the skin and scalp, in which the author stresses the differences of response of the ichthyotic and the seborrhœic person. The second chapter discusses the complexities of the eczema-dermatitis group, under the general heading, Toxic Dermatoses of Epidermal Origin, and succeeds in presenting a fairly comprehensible picture of this still somewhat obscure reaction. Infantile eczema is included in this section, and the paragraphs on differential diagnosis, prognosis, and treatment are models of brevity and succinctness. "Stasic" (? static) ulcers of the leg afford the author an excellent opportunity of proving his originality. "Most of our patients with leg ulcers do not have varicose veins, and most of those being treated for varicose veins do not have leg ulcers." Aphorism or epigram—the statement will be substantiated by all who have had much experience in the O.P. clinic, and are not the slaves of text-book assertion. Chapter V., which is constantly referred to in the rest of the text, is essentially a monograph on the neurodermatoses, which evidently have been especially studied by the author. A diagrammatic representation of his conclusions (facing p. 64) will provide the reader with much food for thought, and a commonsense plan on which to base his treatment of an increasingly frequent epidermal syndrome. The following two chapters extend this field of functional skin disease to a degree which to those graduating from the schools of Hebra or Unna may appear somewhat dangerous. Pruritus ani, and pediculosis vulvæ, pediculosis capitis, dyshidrosis (surely a retrograde step?), and "neurotic" excoriations are all included and given pride of place in this group. Beginners

who come across this work should beware of adopting too literally opinions, which to the seasoned observer seem more conjectural than convincing. Succeeding chapters on the papulo-squamous eruptions, physical (e.g., light produced) dermatoses, vascular, pyogenic, mycotic, and parasitic diseases follow more orthodox lines. A chapter on the "skin in industry" and an appendix of simple formulæ conclude a volume which will prove of value to the more advanced student or teacher of an increasingly important branch of medicine.

2. The practitioner will find in this book, which has achieved three editions in as many years, all the information he is likely to need on the practical side of dermatology, and more than he is likely to be able to apply in therapeutics. The illustrations are excellent, and have been increased in number. A new feature, and one that must have given the author much labour, is the duplication of all prescriptions in metric as well as in apothecaries' weights and measures. It is one which is certain to appeal to the continental reader, and maybe, render a translator's task less difficult. The addition of a paragraph on gold dermatitis, now supplied, was badly needed, for it is probably one of the most frequent if not the most troublesome of all drug eruptions at the present time. As an introduction to the study of dermatology there is no better manual in the English language.

Prescription Writing and Formulary

The Art of Prescribing. By CHARLES SOLOMON, M.D., Assistant Clinical Professor of Medicine, Long Island College of Medicine. London: J. B. Lippincott Company. 1935. Pp. 351. 21s.

NEARLY every text-book of prescribing published in the last thirty years has deplored the habit of using ready-made formulæ, particularly those dispensed in compressed form as tablet, pills, and so forth. It has been reiterated that if the physician is to be independent of the complex pseudo-mysteries of the drug factory, he must be able to write a prescription, with the implication that the education of the medical student is defective, in so far as it relates to prescription writing. Dr. Solomon evidently subscribes to this opinion, and has prepared this volume with a view to providing a sound scientific basis for prescription writing. The work is indeed wonderfully complete. The introductory chapter includes a brief account of the history of the prescription, a discussion of a number of important practical considerations, and a useful review of methods of administration. The second part contains everything anyone need know about prescription writing, including dosage and incompatibility. The rest of the book consists of a formulary which contains a very large number of prescriptions of the more commonly used drugs. These are arranged systematically according to the therapeutic effect expected of the drugs, and are printed both in Latin and in English. The author is careful to point out that they are not intended to be set or standard prescriptions, but rather to illustrate the simplicity of rational prescribing. At the same time, the young practitioner will find in them a comprehensive source of information. To add to the usefulness of the formulary, an index of prescriptions according to symptoms and diseases has been included, as well as a general index. The book as a whole perhaps contains too much information for the needs of the medical student, but should prove a handy work of reference for the practitioner.

THE LANCET

LONDON: SATURDAY, FEBRUARY 22, 1936

THE GENTLE SURGEON

OUR readers will be grateful to Mr. FAGGE, Hunterian orator this year, for his scholarly picture of one of the great figures of Victorian surgery. JOHN HILTON was a truly great man, but, lacking perhaps the spectacular personality of many of his contemporaries, he has never received that recognition which his merits demand or his influence on surgical thought and practice would justify. His name is known to every student in Hilton's method of opening an abscess; his lectures on Rest and Pain are familiar in name to the majority, and in substance to the more industrious. But his contribution is more than a technical device and a series of clinical observations, many of which have been disproved by later knowledge. The quotation which heads the oration gives a clue to the spirit that animates all HILTON's writings, a spirit that shows him to have been a scientific and thoughtful surgeon, perhaps the first of a type, which, it is to be hoped, characterises the best of surgery to-day. To say that he was the first implies no disparagement of JOHN HUNTER. HUNTER was an intellectual giant; he moved and thought on a higher plane than other men, and the standards by which we judge them seem to fit him not at all. But his great and restless spirit was engaged upon the problems of disease in general, while HILTON's gentle and practical mind studied the more intimate problems of Nature's own surgery as exemplified in the patients who came under his care. HILTON was no mean anatomist, as his numerous dissections, immortalised in wax by the art of JOSEPH TOWNE, bear witness to-day. But he was very much more. His interest in the body was not confined to the study of its dead framework, and to the discussion of theories as to how structures ought to work which had ceased to do so; he watched these same structures in life, striving to learn for himself how they carried out their duties in health, and how they attempted to repair their injuries. He was the first physiological surgeon, set apart from his fellows by his faith rather than his works. They study attack, he defence; they consider what can be done to an organ, the limits of its endurance, the best approach to it, the instruments and methods of anæsthesia suited to the enterprise they contemplate; he considers how it works in health, how its working has been modified or vitiated by disease or injury, how it is attempting to repair or circumvent the damage it has suffered, how best he himself can aid these efforts, or how imitate the normal function if repair is impossible. His handling is characterised by a regard for the tissues as purposeful, almost sentient agents of repair. Above all things he is gentle.

Many, especially those who have passed through the wards within the last five years, will consider that gentle handling is the aim of every surgeon. That this spirit should be abroad to-day is the greatest monument to HILTON's influence, for it has not always been so. Surgical history indeed contains the names of others who thought as HILTON, of men who have spoken as did AMBROSE PARÉ: "I dressed his wound; God healed him." But most of the older surgeons were men of action rather than of thought, as they had to be before anæsthesia or antiseptics were known. The tales that come down to us are of uncouth choleric men, of retorts whose discourtesy has made them classic, of bold and skilful but brutal manipulations, of blood and agony, of boastful self-assertion, of fierce quarrels, of chicanery and nepotism. It might have been expected that gentleness would come when anæsthesia had abolished the need for speed; but the same agent made more extensive operations possible, so that the need for speed remained. With the coming of asepsis, a whole new field of operative work, as yet unexplored, was thrown open. Bold and untried adventures, such as the early exploration of the abdomen, could only be carried through successfully, at a time when anæsthesia was still understood imperfectly and shock not at all, by surgeons who worked at lightning speed. We therefore find that during the first few years of this century the ultra-rapid operator was undisputed king of surgery, or at any rate of surgical practice. Slashing his way through tissues in a manner that would horrify the student of to-day, he was able to show that the operations which have since been perfected were possible. His patients survived, his ventral herniæ were closed by others; and his methods have since been changed beyond recognition.

It is perhaps unduly optimistic to say that rough surgery is extinct to-day. Human nature, and especially adolescent human nature as exemplified by the medical student, will always prefer the spectacular to the artistic, and the gentle surgeon is often a gentle man. He may find to his chagrin that the best students flock where the blood flows most freely, where the shouts are the loudest, where instruments are thrown about the theatre, where "look and see," the infallible solvent of diagnostic difficulties, ensures an abundant succession of tours de force. Yet he has his reward when the same men, older and wiser, come to him as house surgeons and registrars to learn those details of tissue kindness which are unseen from the gallery. For this Hiltonian surgery is taught and propagated by apprenticeship. Men speak of Halsted technique, Lane technique, Moynihan technique, each meaning the same thing, the standard of work of a great master at whose side he has studied, a standard whose only criterion is that the tissues shall be treated with the greatest gentleness, subjected to the least damage, replaced carefully, apposed accurately—in short, that they shall bear the least trace of the surgeon's passage. Such methods gain adherence by their results rather than their

performance. Their victory is symbolised by the disappearance of the old operating "theatre," suited for the dramatic in surgery, and its replacement by what is almost an operating temple, where the faithful can study essential detail. Their performance is made possible by better anæsthesia and more highly skilled assistance, which have eliminated the need for hurried work, so that only its quality need be considered. Their perpetuity is assured by a new school of young men, trained in the use of their hands at a time when they can acquire the touch of an artist.

The change, like all important changes, has been gradual, but on a ten-year period it is obvious enough. During the last decade operating by the clock has become a bad joke, traumatic muscle cutting and nerve damaging incisions in the abdominal wall have disappeared, hæmorrhoids has become universal, strong antiseptics, purgation and starvation, have been abolished from the surgical ward. If we made the interval of survey 20 years instead of 10, we might have to admit that the surgical registrar of to-day is a better operator than the leading surgeon of 1915. There is still room for improvement, particularly in the technique of those operations which are not considered to be major surgery. Hæmorrhoids are still torn rather than dissected out; the average operation for hernia is still coarse, traumatic, and unphysiological; and even the gentle surgeon is often content to apply his principles to the deeper layers only, forgetting the physiology of the skin and subcutaneous tissues. Yet the day is clearly not far distant when all operations will be done with the unhurried exactness of the surgeon-neurologist, when all scars will be the invisible line of the plastic surgeon. For the beautiful scar is more than a work of art. Wherever placed it is proof of healing, not merely without sepsis but without any recognisable reaction of repair; it is a guarantee of lasting comfort for the patient and of untainted soil for the man who may have to come afterwards. It is the signature of the gentle surgeon.

SHORT-WAVE THERAPY

SINCE J. W. SCHERESCHEWSKY published his first papers on short (wireless) wave therapy in 1926 the subject has become one of clinical and scientific interest, owing to the many reported discoveries and the claims for effective treatment which have been made by research workers and clinicians. While the application of the new therapy requires technique as exacting as that of X ray treatment, it is desirable for all of us to be aware of the principles on which it is based. Short-wave therapy has come to mean treatment with electromagnetic oscillations of very high frequency, corresponding to a wave-length of 2 to 20 metres. The energy is produced by an electronic tube generator or a spark-gap apparatus, the principle in each case being similar to that of the wireless transmitter, with the fundamental difference that the energy so produced is not radiated by an antenna but is utilised in the body

of the patient in the following way. The characteristic feature of a so-called resonance-circuit, consisting of self-inductance coil and condenser, is the fact that when the self-inductance and the capacity bear a certain simple relation to the wave-length the most part of the produced energy is absorbed. It is always possible to satisfy this numerical condition and thereby to bring the resonance-circuit into tune with the generator by suitably adjusting either the coil or the capacity. In short-wave therapy the part to be treated is brought into the condenser field, thereby becoming part of the dielectric and also part of the tuned resonance-circuit. The metal electrodes or condenser plates make no direct contact with the skin, being separated from it by glass or some other insulating material, and whereas in other electrical methods of treatment the electric energy may be regarded as flowing through the body, in short-wave therapy it appears to act directly on each element of the tissue between the plates. The amount of energy absorbed in this manner at a given point depends on a number of more or less independent factors, such as uniformity of field, dielectric constant, high-frequency conductivity, colloidal structure, potential gradient, but to the best of our present knowledge it is practically all converted into heat. Theoretically the choice of wave-length is a critical factor, but experts are not in agreement how this effect of wave-length is to be utilised in treatment. Substances with different physical constants, placed in the condenser field under the same conditions, are heated to different degrees; for each substance there is a definite wave-length with which, for a given field strength, the heat produced is maximal. If a mixture of different substances is brought into a condenser field, one or other of them can be heated differentially, provided the proper wave-length is selected, whatever its position in the field in relation to the other substances.

Now the human body consists of a number of tissues with different physical constants—fat, muscle, bone, blood, and so on, and if the facts just mentioned are accepted it should be possible to heat one tissue differentially whatever its position in the body. This has been done in treatment of the kidneys within the intact body—it was found possible to coagulate kidney-tissue without burning the skin—showing how potent a weapon has been put in our hands with which to influence deep-seated processes. Indeed, the importance of the new therapy lies in the possibility which it provides of introducing large quantities of thermal energy into the interior of the body without unduly heating the skin and the superficial fat. Much research too has been done on the influence of short waves on animals, bacteria, colloids, and other biological substances. One of the chief problems was to find out whether the effects produced were due exclusively to the production of heat, or whether there might be a "specific" effect which cannot be attributed to heat. Opinion is fairly divided on the point, but it seems that the behaviour of bacteria and certain chemical effects can only with great

difficulty be explained without presuming some form of specificity.

Important as these problems are, the practitioner is more anxious to be told what kind of disease can be successfully treated by short-wave therapy and what advantages, if any, the treatment may have over other methods of applying heat. It may, we think, be taken for granted that the possibility of direct heat formation in any deep-seated organ must have important consequences. The range of indications is widened by the inclusion of organs which could not be reached by diathermic treatment; chronic inflammation in bones, joints, tendons, sinuses, and internal organs, including the lung, is known to have responded favourably to short-wave therapy, and sometimes where every other treatment had failed. Striking results are claimed for sciatica and neuritis, and some diseases of the arteries, and whereas diathermic currents cannot be applied with impunity to acute inflammatory processes, short-wave therapy scored its first successes in the treatment of boils, carbuncles, and cellulitis. Those who wish to pursue the subject further will find excellent and detailed information in several books recently reviewed in our columns.¹

SEX AND CULTURE

THE word "sublimation," borrowed from chemistry, has been adopted by psychologists to describe the process by which the energies of sexual impulses which are denied direct outlet can be applied to non-sexual or social ends. In the years immediately following the war, when the writings of FREUD were being actively debated in this country, the conception of sublimation did something to mitigate the harshness of psycho-analytic theory, and it was much stressed by those who desired to reconcile the lessons of medical psychology with the religious and moral aspirations of civilised man. But few attempts were made to bring the idea of sublimation as understood by psychologists into relation with the new science of social anthropology. A noteworthy contribution to this aspect of the subject was made by Mr. J. D. UNWIN, Ph.D., in a long and painstaking treatise² embodying ideas which, previously summarised, had already evoked critical and appreciative discussion. The suggestion, he tells us in a preface, had been put forward by analytical psychologists that, if social regulations forbid direct satisfaction of the sexual impulses, the emotional conflict thus generated is expressed in another way, and that what we call civilisation has been built up by compulsory sacrifices in the gratification of innate desires. His monograph is the result of an attempt to test this hypothesis by reference to cultural data.

The task is one of quite unusual difficulty and complexity. The first and perhaps the most formidable difficulty which confronted the author was to devise satisfactory criteria of what respectively constitutes cultural progress and sexual

opportunity. The available evidence fell under two main headings—historical and anthropological. The historical evidence was found to be too unwieldy, partly because of its bulk and partly because of the cultural stratification which exists in all civilised societies and makes it impossible to generalise about the cultural stage reached by any civilised society taken as a whole. Dr. UNWIN therefore confined himself to anthropological data. When we talk about the cultural stage reached by an uncivilised society, what do we mean? The following restricted definition is presented: "We can sum up the matter," he writes, "by saying that to the members of every uncivilised society a certain power . . . manifests itself . . . in the universe, and that steps are taken to maintain a right relation with it. . . . The evidence is that different societies conceive of these powers in different ways and adopt different methods in their efforts to preserve a right relation with them. The manner in which the powers are conceived, and the steps which are taken to maintain this relation, constitute the cultural condition of a society in the sense in which the phrase is used throughout this thesis" (our italics). Uncivilised societies are then divided into three groups—described as deistic, manistic, and zoistic—depending on whether they build temples—which are carefully defined (deistic), whether they pay post-funeral attention to their dead without building temples to them (manistic), and whether they do neither. Much careful thought and writing is devoted to describing and differentiating these three cultural conditions. But a definition of what is meant by sexual opportunity is no less necessary to the argument. Dr. UNWIN found it necessary here to limit his discussion to the prenuptial opportunity afforded to females; evidence of an objective, or, as Dr. UNWIN prefers to call it, a behaviouristic character, is only available here, and he points out that the limitation is not as arbitrary as might at first appear, because the sexual opportunity afforded to males in a given society is a reflection and corollary of that afforded to females. First, young women (and therefore young men) may be sexually free, being checked in no way from any sexual activity or play; secondly, prenuptial intercourse may be limited, for a young woman, to a certain man (the restriction imposing correlative restrictions on the males in her community); lastly, the girl may be compelled to maintain her virginity until she is married, it being required that tokens of virginity be required on the nuptial mat. In assessing these groupings, the existence of certain specific exogamic relations and prohibited degrees are always taken into account and no notice is taken of the compulsory continence inflicted by these. The remarkable conclusion emerges that the correlation between the cultural stage attained by a given society and the degree of prenuptial restraint imposed upon its females is complete. Throughout the 80 societies of which the required information was available it was found that each of the three types of sexual opportunity was invariably accompanied by one of the three types

¹ See THE LANCET, Nov. 16th, 1935, pp. 1125-26.

² Sex and Culture, London: Humphrey Milford, Oxford University Press. Pp. 676. 36s.

of cultural behaviour. Societies which permitted prenuptial freedom were in the zoistic condition; those which inflicted an irregular or occasional continence were in the manistic condition, and those which insisted on complete prenuptial continence were in the deistic condition. In each society the converse obtained; the correlation found indeed was so complete as to astonish the author, who, in his preface, declares that if he had realised, when he embarked on his task, how greatly he would have to revise his social philosophy, he might have hesitated to begin it.

At a recent meeting of the medical section of the British Psychological Society Dr. UNWIN's conclusions³ were keenly though sympathetically discussed. Their extraordinary importance, if true, for all departments of human aspiration and endeavour was acknowledged by Prof. J. C. FLUGEL, who described their implications as at once hopeful, startling, puzzling, and depressing. Hopeful because the work implied a new phase in coöperation between anthropology and clinical psychology. Startling because the definiteness of the results was without parallel within the domain of the purely human sciences. Puzzling because they went too far; for, if the correspondence between sexual limitation and cultural achievement was so complete, psychologists must all have been wrong about the existence of other factors. Depressing because of the unpleasing clarity with which the ethical alternatives of pleasure or progress

³ Dr. Unwin's address at this meeting has since been published as a brochure, "Sexual Regulations and Cultural Behaviour" (Humphrey Milford, pp. 62, 2s. 6d.), which is a summary of the evidence and conclusions contained in his treatise.

as the summum bonum were put before the human race. "To puritans of all denominations," he said, "as well as to the more fanatical enthusiasts for progress, Dr. Unwin's views should be most welcome, since they seem to provide at once ample 'scientific' justification of the demand for purity and abstinence together with a sure recipe for further cultural advance. These same views, however, are likely to cause consternation in bohemia." And at the same meeting Mr. R. E. MONEY-KYBLE, Ph.D., questioned the validity of the causal relation which might be thought to subsist between compulsory sexual continence and social progress. They might both be collateral effects of some other cause.

Dr. UNWIN's book is the product of ten years of industrious research. It marshals a wealth of carefully digested facts. It is written with a clearness and conciseness very rare in works of this length. The author is acutely conscious of how, in anthropology as well as in psychology, loose thought can be embodied in a loose usage of words. The precision with which he defines his terms and phrases, while making difficult reading of some of the chapters, will provide intellectual pleasure to many critical readers. Some no doubt will extend the field of comparison to other manifestations of sex and to other aspects of culture. Some will analyse the same data to see whether they cannot be interpreted in other ways. Whatever may be the outcome Dr. UNWIN has shown himself a pioneer in a new and very interesting branch of statistical sociology, and his book may well exercise an important though unobtrusive influence upon social and moral thought in the next generation.

ANNOTATIONS

THE WORD "VENEREAL"

A CHANGE in the title of the *American Journal of Syphilis and Neurology* to the *American Journal of Syphilis, Gonorrhoea, and Venereal Diseases* for discussion, in the January number, on the meaning of "venery" and "venereal." Strictly speaking the terms refer to the worship of Venus, and so their connotation covers the art of love in wedlock as well as outside it. But the "Oxford English Dictionary" brands them with the stigma of lust in quotations as early as 1610; and there is no doubt that popular feeling for centuries has limited their meaning to illicit intercourse and the diseases that arise therefrom. The six generally recognised as venereal are syphilis, gonorrhoea, chancroid, lymphogranuloma inguinale, scabies, and pediculosis pubis; and it will at once be observed that most of them can be acquired without any suggestion of venery. It is therefore natural that well-meaning people should wish to drop a word which casts a slur on the good name of many innocent people. With this in mind attempts have been made from time to time to suppress altogether the word venereal as an "offensive outworn relic of the Victorian age." Indeed it has been said that the association in the lay and medical mind between venereal disease and sexual guilt is so close that no great advance in control is likely to take place until the name has been changed.

Now it is a common weakness of human nature to try to substitute a new or more respectable word

for one that has lost its character. Sometimes the effort is successful, especially if it is a new word such as Fracastor's "syphilis" for *Morbus Gallicus*. Sometimes it is tolerated, as when we substitute hospital for infirmary or asylum. Sometimes it is just stupid, as when we say "officer" for policeman. A recent manifestation of this futility is the suggestion that venereal diseases should be called "social diseases." If such an attempt were made all we should succeed in doing would be to degrade a comfortable pleasant word like "social" without making any difference to the public outlook on the conditions in question. For our part therefore we are not in favour of suppressing the word venereal, covering as it does a well-defined group of diseases, several of which can be acquired together. Instead we think that it will survive, because of its age and usefulness. One regret, however, may nevertheless be associated with this belief. Those of us who have strong feelings about the marriage of Greek and Latin might be tempted even to sacrifice venereal if we could thus guarantee to slay the barbarous hybrid "venereologist."

DEATHS ATTRIBUTED TO ANÆSTHESIA

The second Emsley memorial lecture delivered at Melbourne in September last¹ gave Dr. Z. Mennell, its deliverer, an opportunity for expressing his views on several questions both of the physiology of anæ-

¹ *Med. Jour. Australia*, 1935, **xxii**, (2), 801.

thesia and of matters germane to the practice of anæsthetics, such as coroners' inquiries. After paying due attention to Embley's well-known work in connexion with the cause of death from chloroform, the lecturer gave interesting and valuable examples of causes of death during anæsthesia which are probably often overlooked because they are not sought for with the microscope, by which means alone they can be detected with certainty. Two causes, of which he cited examples and in illustration of which he showed slides, are fat embolism and air embolism. The symptoms exhibited by a patient who died on the operating table were so unlike those attending other fatalities which Dr. Mennell had seen associated with anæsthesia that he found himself unable to give the coroner any opinion as to the cause of death; nor was this demonstrable from the post-mortem inquiry until days after, when slides had been prepared by Prof. Dudgeon. These showed fat embolism to such a degree that, the lecturer said, "there must have been several pounds of liquid fat present." It is not very unusual for deaths during anæsthesia to be unexplained by the naked-eye post-mortem examination, and the conclusion is commonly drawn that the death resulted from a fatal effect of the anæsthetic, presumably on heart or respiration, which is not demonstrable after death. Dr. Mennell has done a service if he has enforced on all concerned the need for more searching inquiry into the causation of these "anæsthetic" fatalities.

TREATMENT OF ENLARGED PROSTATE WITH MALE HORMONE

THE thesis that some kind of endocrine dysfunction is responsible for benign enlargement of the prostate has attracted much attention from experimentalists in recent months, and was briefly discussed in our columns as recently as Feb. 8th (p. 321). The general opinion is that the hyperplasia is a response elicited by œstrogen compounds, but McCullagh and Lower^{1,2} elaborate a contrary view that it results from imbalance between two separate normal testicular hormones, secreted by the seminiferous tubules and by the interstitial cells. It will be recalled that Dr. Paul Niehans accepted this view in his paper recommending treatment by "Steinach's ligature II"; but it must be admitted that the evidence in favour of the existence of two such hormones is still somewhat indirect. Gonadectomy in both male and female rats leads to enlargement of the pituitary and to enhancement of its gonadotropic powers. If two rats, the one castrated the other normal, are experimentally combined in parabiotic union, the accessory reproductive organs of the normal animal become hypertrophic, presumably because its gonads are stimulated by the excess of gonadotropic hormone elaborated by the castrated animal's pituitary. If, however, enough male hormone is injected into the castrated animal to save its prostate from hypertrophy, its pituitary does not become over-active, and the accessory reproductive organs of the normal member of the parabiotic pair do not enlarge. These observations show that testicular hormone influences both the accessory reproductive organs and the pituitary, and the presumption is that while its effect on the accessory organs is to increase their activity, its effect on the pituitary is an inhibitory one.

McCullagh argues that two distinct substances,

with sharply different functions, are responsible for these separate effects. This opinion is founded chiefly on changes observed after irradiation of rats' testes with X rays. Such irradiation leads to degeneration of the tubular elements, while the interstitial tissue remains normal and the accessory reproductive organs hypertrophy. The pituitaries of the irradiated animals also become over-active, in the same way as the pituitaries of castrated animals. Thus a single experimental procedure enhances one testicular function (promotion of growth of the accessory organs) and depresses another (inhibition of pituitary hyperactivity). Indications of similar differential changes in testicular function are provided by other experiments, and McCullagh therefore concludes that the interstitial tissue of the testis elaborates a hormone which governs the well-being of the accessory reproductive organs, while the tubular system produces a hormone which prevents the pituitary from becoming gonadotropically hyperactive. As he himself points out much remains to be done, not only in the provision of new data, but also in the confirmation of older findings and in the resolution of conflicting observations, before this hypothesis can be regarded as sound. Despite these uncertainties, however, McCullagh and Lower advance the following conception of the ætiology of benign enlargement of the prostate. The condition, they suggest, is due to insufficient production by the testes of a hormone—to which they give the name "inhibin"—which normally prevents the hypophysis from secreting too much of its gonadotropic principle, and to a consequent hypophyseal over-activity which stimulates excessive production of the testicular hormone concerned with the growth and maintenance of the accessory reproductive organs, including the prostate. If this view of the ætiology of enlarged prostate is correct, the obvious treatment for the condition is administration of the testicular substance "inhibin." This substance, however, has never been isolated; and accordingly, in his investigation of 76 patients, Lower had to compromise by giving each the equivalent of 60 grammes of fresh beef testicular material daily. Some of the patients at the beginning of the trial suffered from complete retention of urine, while others had nocturnal frequency and varying amounts of residual urine. Nevertheless as many as 48 reacted favourably, the improvement of symptoms being usually manifest within a week or ten days after treatment was started, and the maximum being reached within 4-6 weeks. But unfortunately the improvement was almost entirely symptomatic, for the size of the prostate, as determined by rectal examination, had as a rule not altered, nor had any histological changes been induced.³

Although he does not favour it, Lower is alive to the possibility that his therapy may actually have been an unimportant factor in the symptomatic improvement of his patients. This is undoubtedly the safe view to take in the absence of any knowledge of the efficacy of crude testicular extracts when given by mouth. In any case, even assuming that the treatment was of value, it is obvious that the material administered may have been useful not because of its problematical inclusion of a substance "inhibin," but because of the male hormone proper which it almost certainly contained. The ætiological hypothesis postulated by McCullagh and Lower is in no way supported by whatever success their treatment

¹ McCullagh, D. R.: Cleveland Clin. Quart., January, 1936, p. 3.

² Lower, W. E.: *Ibid.*, p. 11.

³ Lower does not state how histological material was obtained.

may have gained, since male hormone is also indicated in the management of benign enlargement of the prostate on the view that the condition results from the prolonged activity of oestrogens. It is idle, however, to speculate, in the present state of knowledge, on these various issues. One thing only is plain. Several hypotheses regarding the aetiology of enlarged prostate have implied that male hormone would be of use in the treatment of the condition. Information about the chemistry and biology of male hormone compounds has also multiplied rapidly in the past year. It is time, therefore, that male hormone was given a fair and adequate clinical trial in those conditions which experimental work suggests may benefit from its use.

WHOOPIING-COUGH AND THE PUBLIC

IN spite of unanimous medical opinion, and the evidence of statistics to the contrary, the public of most countries continues to regard whooping-cough as a disease of little account. Dr. F. Barbary, of Nice, in a communication¹ to the Paris Academy of Medicine, deplors the indifference shown in the rural districts of France. Evidently an optimist then, he is disappointed now, seeing that since he drew attention to the matter ten years ago nothing has been done. Dr. Barbary alludes to the well-known fact that the actual numbers of cases and deaths from whooping-cough far exceed those known to the sanitary authorities. From personal inquiry he found that, although very few cases had been notified voluntarily, several hundreds of children had been attacked by the disease in the district he surveyed and of these many had died from pneumonia or broncho-pneumonia, the true cause of which, namely whooping-cough, had not been revealed on the certificate. Dr. Barbary advocates the education of the public by means of addresses and handbills. In his view, it is essential to explode the legend of the efficacy "du fameux changement d'air," since removal of the child results not in the amelioration of the attack but in the spread of infection to a fresh locality. He deprecates, too, the practice of permitting children suffering from the disease to play with others in the street. At intervals, games are interrupted while the sufferer, during a paroxysm, sprays his playmates with infection. It should be impressed upon the public that a few minutes' contact with an infective child are sufficient for the transmission of a disease which, far from being trivial, may result in fatal complications. Dr. Barbary declares for compulsory notification in order that specific measures may be taken for the detection of suspects and the protection of contacts. Early diagnosis is facilitated by the cough-plate method and should be followed by isolation. For the contacts Dr. Barbary advocates either passive immunisation by means of convalescent serum or active immunisation by means of vaccines.

The problem of the control of whooping-cough in rural France presents the same features in urban England. It is true that in the large cities a commencement towards its solution has been made by hospitalisation upon a fairly large scale; at the present time, for example, not far short of 700 children suffering from whooping-cough are in the wards of the infectious diseases hospitals of the London County Council. Since, however, as is the case in measles, patients are removed to hospital only when the phase of maximum infectivity has passed, hospitalisation is mainly a curative measure.

Vaccine prophylaxis, when adequately attested, may provide the real solution of the problem if the public, as the result of education, agrees to the necessity.

A PIONEER OF ACTINOTHERAPY

A MEMORIAL to Albert Jesionek in the *Münchener medizinische Wochenschrift* of Jan. 31st is a worthy tribute to the work and personality of an outstanding dermatologist of modern times. In this country he will be remembered chiefly for the remarkable results he obtained in all forms of cutaneous tuberculosis by purely "natural" means—viz., diet and sunlight—at his Lupusheilstätte at Giessen. In this achievement his clinic was probably unique, for his energies were concentrated on the dermatoses; neither pulmonary nor articular cases, as in many other "biological" institutes, shared the available space and facilities. Jesionek was a long way ahead of his time in formulating his problems and visualising them broadly as biological. He was no slave to this or that type of diet, lamp, or local application, and he was rarely seen at medical congresses with some new gospel of cure or prevention. He preferred the quiet atmosphere of his now famous institute at Giessen, and consistently refused the offer of larger and more important spheres of scientific activity. He will be remembered with Finsen, Rollier, and the other pioneers for his services to actinotherapy and the management of cutaneous tuberculosis.

ASPIRATION FOR MAMMARY ABSCESS

DISSATISFIED with the results of incision and drainage in a carefully controlled series of 42 cases of abscess of the breast, Mr. R. J. V. Battle and Mr. G. N. Bailey resorted to aspiration and lavage of the abscess cavity.¹ As irrigating fluid they used at first "bouillons vaccins," and later Dakin's solution, and they report results from aspiration which compare favourably with those of incision. To their recommendation of aspiration as a routine treatment there are exceptions—notably the very large abscess that results from neglect of a small, localised one, and the diffuse cellulitic type of infection which shows poor localisation and severe constitutional reaction from the start. The combination of a virulent infection with a poor physical condition probably accounts for the incidence of this type of breast infection. In general, Battle and Bailey believe that the cause of breast abscess is engorgement followed by infection of the stagnant secretion by organisms present in the ducts or gaining access to them by way of the nipple. Cracks of the nipple increase the liability to infection in so far as pain leads to curtailment of suckling and hence to engorgement. Aspiration is most successful when infection remains localised, but watch must always be kept for multiple infection. Where the suppurative process is of the cellulitic type it is better to incise and explore with the finger until all pockets have been opened into one main cavity. Before starting aspiration, the baby is taken off the affected breast, which is emptied by a pump. Battle and Bailey use a 25 c.cm. syringe and a needle of 2.5 mm., and they have two or three of such needles in readiness. They prefer a syringe with a Luer fitting instead of the Record, which is too narrow in calibre. The breast surface is cleansed with ether, and a point with definite fluctuation, or, in patients seen before this is present, a point of maximum tenderness, is selected. Novocain (2 per cent.) is injected through the tissues down to the abscess cavity. The wide-bore needle is inserted, the pus aspirated, and an equal quantity injected

¹ Bull. Acad. de Méd. de Paris, 1936, cxv., 192.

¹ Brit. Jour. Surg., January, 1936, p. 640.

of Dakin's solution, diluted half and half with water. A sling supports the breast and the patient is re-examined in 24 hours. Further aspiration and injection is undertaken if pain returns from increased tension in the breast, if tenderness persists or returns, and if the temperature does not fall satisfactorily. Two or more areas of tenderness can be aspirated separately and the Dakin's solution washed to and fro between the cavities. Repeated aspiration is required in most cases. Incision is necessary if, in spite of repeated aspiration and careful search for hidden loculi, the condition fails to settle.

"Bouillons vaccins" were given a fairly extensive trial and the results were satisfactory. The method used was that described by V. Riche and E. Mourgue-Molines, except that non-specific vaccines were employed in some cases, and, incidentally, with results superior to those with the "bouillon vaccin No. 31" recommended. Special permission from the Ministry of Health is required to import these products and customs duties have to be met. Dakin's solution was found to be more practicable and to give good results, hence it was preferred. Weaning of the baby and the provision of extra nourishment and of general ultra-violet radiation proved useful in some of the more severe cases.

RESPIRATORY EFFICIENCY TESTS FOR EACH LUNG SEPARATELY

MENTION has already been made in these columns of the bronchoscopic methods devised by Jacobæus and his colleagues whereby the vital capacity and other measurements could be obtained individually for the right and left lungs. Bezançon and his associates recently reported¹ to the French Academy of Medicine their experiences with a modification of the original scheme. To avoid any risk of injury they have employed a standard bronchoscope of normal calibre (7 mm.) and catheterised the lungs consecutively rather than simultaneously as in the method devised by Jacobæus. Once the bronchoscope is in the main bronchus insufflation of a rubber bag round its end blocks all exit of air except through the tube, and the expired air can be collected and analysed so as to give exact data on pulmonary ventilation. The present communication is based upon the examination of 30 patients most of whom suffered from pulmonary tuberculosis. A close connexion was usually found in this condition between X ray findings and the measurements of pulmonary ventilation, but the functional activity of a diseased lung sometimes turned out to be higher than radiography had indicated. This could either mean that this lung was less damaged than appeared, or, alternatively—since figures obtained were not absolute but relative for the two lungs—that the apparently sound side was not contributing to the total pulmonary ventilation as large a share as radiographic and physical examination would suggest. Interesting comparisons are made between pulmonary and renal disease as estimated by efficiency tests. For example, in pulmonary tuberculosis lesions apparently limited to a relatively small area have been found to be associated with a substantial decrease in functional activity, whereas patients with lung abscesses apparently involving a large area of tissue may show comparatively little change in the proportion of pulmonary ventilation carried out by the diseased and the normal lungs. The same thing happens in the kidney, where non-tuberculous suppuration causes less interference with renal efficiency than a

tuberculous lesion. An extreme example of interference was seen in a patient with a neoplasm of the lung in whom respiratory function was almost suppressed on the affected side.

More work is required to clear up the many unsolved problems. For instance, separate study of the ventilation of each lung often shows that elimination of carbon dioxide and intake of oxygen are diminished in different proportions, and the question arises whether there can be a different respiratory quotient for the two lungs.

AMBULANCE SERVICES IN ETHIOPIA

THE British Red Cross Society's second ambulance unit, destined for Gondar on the north-western front, landed at Port Sudan on Feb. 16th. The officer-in-charge is Dr. Percy James Kelly, C.B.E., and he is assisted by Dr. Robert Blackwood Robertson. Three non-commissioned officers, formerly R.A.M.C., accompany the unit and two Indian sub-assistant surgeons are proceeding from Kenya to join them, as well as nine native dressers. Captain Strudwick, the transport officer, is already in the Sudan making all transport arrangements—a vital and extremely difficult task. It is expected that the unit will have reached Gondar and be ready to begin work early in March. Meanwhile the first unit,¹ under Mr. John Melly, has moved from Dessie, where it was originally stationed, to Waldia, and treated 2000 cases in the fortnight following its arrival. It is now preparing to move some sixty miles further north to Quorem on Lake Ashangi to work as a clearing station for wounded from the Makale front. Mr. Melly reports that the unit is working smoothly, in spite of rains and almost insuperable transport difficulties. Unfortunately, however, it is found that the very severely wounded, being unable to walk, never reach a dressing station at all, and either die from their wounds or have their sufferings ended by their comrades. The wounds of those who reach the unit—many of them caused by bombs—are always in an advanced state of sepsis and immediate amputations are often necessary. The civil population are beginning to bring in their sick at the rate of some 90 new outpatient cases a day, and the members of the unit are called upon to treat many types of tropical disease. The varied equipment with which the unit is furnished is standing them in good stead, but a portable X ray set has been found to be a necessity, and a set which is being specially manufactured will be dispatched within a few weeks in the charge of an experienced radiologist. Public response to appeals for funds, including a broadcast address by the Very Rev. H. R. L. Sheppard, has covered the expenses already incurred in dispatching the two units, but money is still urgently needed to ensure that their work shall be adequate and uninterrupted throughout a campaign which at best is bound to cause widespread suffering for many months to come. This work is carried on under difficult and dangerous conditions and the units have to depend entirely on supplies sent from this country, so that the British Red Cross Society has to find at least £3000 a month for their maintenance in the field.

It is also announced that a party of British nurses is being formed under the leadership of Gertrude Lady Decies to join the Ethiopian Red Cross in the war zone. This is separate from the British Red Cross units (composed only of men) and no general appeal for funds has yet been made; but a sum of £2000 is

¹ The first unit is composed of the following medical men: Mr. John Melly, F.R.C.S., Dr. A. C. W. Barkhüus, Dr. C. E. Bevan, Dr. W. S. Empey, Dr. J. W. S. Macfie, and Dr. John Perverseff.

¹ Bezançon, F., et al.: Bull. de l'Acad. de Méd., 1936, cxv., 12.

needed, of which a quarter has already been subscribed. Among other voluntary efforts of the same kind we may lastly mention the veterinary unit organised by the R.S.P.C.A., which has lately sailed with all that is necessary to staff and equip a field hospital for 250 sick animals.

A PIONEER ALMONER

Miss Anne Cummins died on Feb. 8th, 1936; her life's work remains vigorously alive. In the future she will be remembered, not as the first almoner, for the profession was actually ten years old when she was appointed at St. Thomas's Hospital in 1905, but as the first almoner with imagination vivid enough to realise the potentialities of hospital social work and in large measure to turn her vision into reality. She saw the work not as a series of sporadic acts but as an essential hospital service ancillary to medicine and nursing and for the benefit of all patients. So quickly did she inspire others with her belief that in 1909, only four years after she had started her work at St. Thomas's Hospital among the out-patients, she was able, thanks to the newly formed Northcote Trust, to carry systematised social work into the wards and into special departments, finally creating in the hospital a complete system of medico-social service which still remains in many ways unique. This success was largely due to the enthusiasm for the work and loyalty to her ideals that she was able to kindle in successive generations of her staff. Those who came to her for wise advice, whether patients, fellow-workers, nurses, or doctors, always left her fortified and stimulated. Her influence extended far beyond the bounds of the hospital. Since 1905 Miss Cummins has played a part in almost every big movement touching the health of the people. Very early she stressed the special importance of social work for the patients suffering from tuberculosis and venereal disease, and was responsible for starting the special hostel connected with St. Thomas's and for the liberal and educational lines on which it has been run. The development of maternity and infant welfare centres owed much to her; and it was she who arranged that fathers as well as mothers came to classes and lectures at the little welfare centre near the hospital. Miss Cummins had nothing parochial in her outlook; she saw the hospital as part of a larger whole. She worked continuously for coöperation and understanding between State and voluntary organisations, and knew how to give as well as to get the best from societies and individuals for the patient in need. From the first she strove for the adequate training for almoner's work, and her own preparation for the work at St. Thomas's Hospital was both long and arduous. In 1907 she was instrumental in forming the Institute of Hospital Almoners for the selection and training of students and for maintaining professional standards of work, and after her retirement from St. Thomas's Hospital in 1929 her work for the institute was perhaps her greatest interest. She lived to see the profession of hospital almoner spreading over the whole of Great Britain, not only in voluntary, but in municipal and mental hospitals, and the development in at least one of our dominions of an institute for training on the English pattern.

SERUM TREATMENT OF TYPHOID FEVER

LAST year Mr. A. Felix, D.Sc.,¹ and Dr. C. J. McSweeney² reported in our columns the results of early trials of a new antityphoid serum prepared by Dr. Felix, and at a meeting of the fever hospitals

group of the Society of Medical Officers of Health on Jan. 31st the same workers gave an account of their further experiences. Felix's investigations with Weil on the H- (flagellar) and O- (somatic) antigens have long been familiar, and more recently he has identified in *Bacillus typhosus* a third antigenic component which he calls the Vi-antigen. While O-antigen is chiefly responsible for toxic symptoms, the Vi-antigen is specially associated with virulence, and he maintains that a therapeutic serum to be of value must contain effective amounts of both O- and Vi-antibodies. Clinical trials of his new serum in Palestine and Egypt have been "definitely encouraging"; both toxæmia and pyrexia were favourably influenced. Comparative trials by Dr. Samy Bey Sabongi of Cairo of commercial serum containing O-antibody in low titre, special serum with O-antibody in high titre, and a third serum containing both O- and Vi-antibodies are held to have demonstrated the superiority of the last. The same kind of serum, at first unconcentrated but later concentrated and of very much higher Vi- and O-titres, has been used by Dr. McSweeney in Dublin in 19 cases of typhoid fever. Although in 10 of these there was unequivocal evidence that the period of pyrexia was shortened, McSweeney found that the effect of the serum upon toxæmia was more striking and more constant than its effect on temperature. Indeed he considers it so potent a weapon in combating toxæmia that its routine use is justified, especially if toxæmic features are in evidence. In the course of the discussion Dr. E. W. Goodall recalled the use of Chantemesse's anti-exotoxic serum (1906) and MacFadyen and Hewlett's anti-endotoxic serum (1908); the latter he had used with good results, and he had also seen benefit from the injection of vaccines. From the examination of 66 case-records he concluded that in 25 instances Felix's serum had proved beneficial, but whether the Vi-serum was superior to the O-serum he was not sure. Dr. A. Joe, who had also examined the records, said he thought that, on the whole, the results were encouraging and that a good case had been made out for extensive clinical trials of the new serum, which, he added, might now be obtained commercially. Hitherto the serum has been injected intramuscularly, but Dr. Stanley Banks suggested that still better results might be obtained from intravenous or intraperitoneal injection. Dr. McSweeney, who admitted to less courage, did not share this view.

WE regret to announce the death on Feb. 7th of Dr. Priestley Leech, consulting surgeon at the Royal Halifax Infirmary, and medical officer in charge of the Venereal Diseases Clinic.

ON Thursday, Feb. 27th, and on the following Tuesday at 5 P.M. Dr. E. L. Middleton will deliver the Milroy lectures to the Royal College of Physicians. He will speak on industrial pulmonary disease due to the inhalation of dust, with special reference to silicosis.

Sir Lenthal Cheatle will deliver the Hunterian oration of the Hunterian Society at the Mansion House at 9 P.M. on Monday, Feb. 24th. His subject will be John Hunter's Time and Ours.

AMIDOPYRIN, after May 1st next, will not be on sale to the public except on medical prescription. That is the day on which the new Poisons List and Rules come into force, and the decision was announced last week by the Home Secretary in reply to a question in the House of Commons (see p. 456).

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXXXIX.—PROGNOSIS IN ENLARGEMENT OF THE SPLEEN*

THE spleen is a composite organ, composed of several tissues which are also to be found elsewhere in the body, and the diseases which involve the spleen affect these tissues not only in the spleen but wherever else they occur. The main tissues which make up the structure of the spleen are:—

1. The *hæmopoietic or blood-forming tissues*—occurring in the bone-marrow and spleen-pulp and (in conditions of disease) elsewhere as well, e.g., the liver.

2. The *lymphoid tissues*—occurring in the spleen as the Malpighian bodies, and elsewhere as the lymphatic glands and lymphoid nodules abundantly scattered through the organs.

3. The *reticulo-endothelial tissues*—occurring as the cells lining the splenic sinuses, as the Kupffer cells of the liver, in the bone-marrow, and elsewhere.

4. The *vascular structures*—arteries with their peculiar endings in "ellipsoids," veins, blood-sinuses. The spleen is in direct connexion with the portal venous system, and is of necessity involved in diseases and abnormalities of that system.

5. The *supporting tissues*—capsule, trabeculæ, and reticulum of the pulp.

Thus the real problems of prognosis arise in diseases affecting other parts or tissues of the body, but in which the same tissue in the spleen takes a share. It may be, and often is, that splenic enlargement is the most obvious clinical sign, but the prognosis is that of the whole disease. The real crux of prognosis is accurate diagnosis, and this may be excessively difficult. I have, in association with various co-workers (Cashin, McMichael, Salah), investigated a large number of spleens removed in Great Britain by operation or at necropsy, and have published accounts of attempts to classify them on a pathological basis. Many of them have been enormously enlarged, but some have been normal in size. So far it has been found quite impossible to make any clinical classification of real value to physicians, and in only a minority of splenic conditions can an accurate diagnosis and a name be given.

In practice, however, prognosis can conveniently be considered under three headings—namely, what happens: (1) when the spleen is left alone; (2) when splenectomy has been performed successfully from the surgeon's point of view; (3) when other treatment, such as by X rays or drugs or other measures, is employed. The conditions in which the various essential tissues of the spleen are involved, and the prognosis in each, will be considered in relation to these three lines of treatment.

Hæmopoietic and Lymphoid Tissues

It is convenient to consider the hæmopoietic and lymphoid tissues together. Here we are concerned with prognosis in all the leukæmias, and certain of the anæmias. It is perhaps easiest to include acholuric jaundice in this group also, but no one at present knows the real causation of this fairly common disease.

The prognosis in all the varieties of *acute leukæmia* is bad, and no treatment applied to the spleen or elsewhere is of any avail. In the *chronic leukæmias* (both myeloid or spleno-medullary and lymphatic),

treatment applied to the spleen has a notable effect on prognosis. We have seen in the last decade an enormous improvement in the results of X ray therapy in these diseases. Everyone is agreed that the prognosis as regards the general health of the patient is vastly improved; not everyone is agreed that the span of life is actually prolonged. The problem is difficult because of the great variation in the expectation of life in untreated patients, particularly those suffering from chronic lymphatic leukæmia. I am convinced myself, from my own observations, that in chronic myeloid leukæmia life is actually prolonged, in addition to good health being temporarily restored, by radiotherapy. As to chronic lymphatic leukæmia, an individual physician does not see enough cases to enable him to form a proper judgment. Instead of being anæmic invalids patients may now hope to continue active work for five, six, or even seven years in the myeloid variety, and still longer in the lymphatic. My longest case of myeloid leukæmia is still alive at the end of seven years. Nevertheless, it must be admitted that in all chronic cases of leukæmia the *ultimate* prognosis is bad, and the onset of hæmorrhages generally shows when the end is approaching. A point of interest is that it seems to be treatment by X rays *to the spleen alone* which is of value in myeloid leukæmia, although so far as we know the actual disease is chiefly in the bone-marrow. It does not seem to matter much whether the spleen becomes shrunken to nearly normal size by the therapy, or remains large—the good result is the same. In chronic lymphatic leukæmia, of course, the position is different, and here X ray therapy should be applied both to the spleen and to every lymphatic gland found to be enlarged.

Hodgkin's disease is a difficult problem in prognosis, for if left untreated it may run an acute or a very chronic course. Its ætiology and even its nature are still obscure. In the spleen it involves the lymphatic elements (the Malpighian bodies), and elsewhere the lymphatic glands and all lymphoid structures. How does X ray therapy affect the prognosis in this disease? Opinions vary, but my own is that in the more chronic cases well-applied X ray therapy, carried out in the closest association with the clinical laboratory, is of great value in prolonging life. This close correlation, with regular blood counts, is essential. Care must be taken, when treating the enlarged glands and the spleen, that the blood-destroying effects of X rays are not carried too far, to produce both severe anæmia and leucopenia, and actually hasten the end. In the past most of us have made mistakes in this way.

Splenectomy has no influence on the prognosis either in the chronic leukæmias or in Hodgkin's disease.

Erythræmia (Osler-Vaquez disease) is a disease associated with great splenic enlargement. In this condition splenectomy is valueless, X ray therapy offers little help, and blood-destroying agents such as phenyl-hydrazin are uncertain and at times even dangerous because of our difficulty in knowing when the hæmolytic action of the drug will stop. Symptomatic treatment by repeated venesection is the only method which has proved regularly helpful in my hands, and I believe improves prognosis in that it tends to prevent well-known complications.

* Enlargement of the spleen associated with tropical diseases is not discussed in this article.

Acholic jaundice (congenital or, rarely, acquired) may be dealt with here for convenience. We know that clinically these patients suffer from periodic attacks of blood destruction, resulting in hæmolytic anæmia and hæmolytic jaundice, and that the spleen is enlarged. We know too that in a test carried out under entirely artificial conditions the washed red blood corpuscles, deprived of their plasma, are unduly "fragile" when compared with the red blood-cells of normal people. Whether the red cells are unduly fragile, in the same sense, within the body, and when bathed in plasma, is quite a different problem, no matter how important the test may be for diagnostic purposes. We also know that splenectomy breaks some link in the chain, and prevents, nearly always, the return of the sudden "blood crises," with blood destruction and jaundice. I formerly believed that splenectomy was an absolute cure for these blood crises, but a single case still under observation has shown me that the rule is not invariable. For practical purposes, however, splenectomy is a true clinical cure for this disease, although when tested after the operation the red cells remain throughout life as fragile as ever.

Prognosis as regards life when splenectomy is not carried out is more difficult to assess, but it is known that many cases of untreated acholic jaundice live long lives. Various complications, however, such as gall-stones, may ensue at quite an early age. Broadly speaking, the view is now held that splenectomy is indicated, and that when it has been successfully carried out a prognosis of continued good health can be predicted.

The problem of the prognosis of *purpura hæmorrhagica*, in its relation to the spleen, may also be considered here. I have examined the spleens removed by operation from a number of these cases, and in none was the organ enlarged, nor could any microscopic abnormality be made out. Here, if we see aright, is a disease involving the blood-platelets, and their production or destruction, in some unknown way. Splenectomy generally raises the platelet count, and it is for this reason that splenectomy has been used in severe and recurrent cases of purpura. It seems true to say that in purpura hæmorrhagica splenectomy may be a truly life-saving measure; but it is also true that splenectomy does not, in all cases, prevent the recurrence of a low platelet count, and a return of the disease.

Reticulo-Endothelial Tissues

Diseases involving these tissues, in the spleen and elsewhere, include the abnormalities of lipid storage, described by Gaucher, Pick, and Niemann, and also the lipid splenomegaly sometimes associated with diabetes. The spleen is here involved merely as part of a much more generalised abnormality in function of the reticulo-endothelial system of the body. The prognosis, except in diabetes, is on the whole bad, and is certainly, in my experience, uninfluenced by any treatment, even splenectomy.

Vascular Structures and Supporting Tissues

This includes the largest group of splenomegalies met with in Britain, and nomenclature is almost as difficult as prognosis. This is the group formerly referred to in our literature as Banti's disease, or splenic anæmia, but a better pathological description would be hepato-lienal fibrosis. The origin of the splenomegaly is quite unknown, but it seems evident that changes in the vascular structures of the spleen are of great importance. In one group of cases of

this kind, indistinguishable clinically from others, the vascular lesion is actually outside the spleen, and complete thrombosis of the main splenic vein or even of the portal vein is found at necropsy. In most cases, however, the vascular changes are within the spleen itself, and are associated with a gradually progressive diffuse fibrosis. The crucial point in the prognosis is the fact that the liver also tends to be involved, developing fibrosis and ultimately a true cirrhosis. The question of whether the spleen changes come first and the liver changes second is obviously of great importance. It is generally believed that this is indeed the order in most, if not all, cases, and this influences both treatment and prognosis. So far as we know at present, our only chance of preventing the progressive changes in the liver is to remove the spleen, and it is generally impossible in the earlier stages to know, without surgical exploration, whether the changes in the liver have begun. There are two schools of thought at present, one favouring splenectomy and one against it. The only alternative to operation is X ray treatment, and my personal view is that this is valueless.

How can a reasonable decision be made as to whether splenectomy should or should not be performed? Only a very extensive experience could help, and few people see, throughout their clinical life, sufficient cases to enable them to formulate definite rules. It is certain that astonishing results have followed splenectomy in the most unpromising cases, when the liver has been proved to be cirrhotic, and even when ascites has set in. On the whole, however, it must be said that at present the prognosis in this group is poor as regards duration of life, and the average expectation under any treatment is no more than five years.

Prognosis of the Operation of Splenectomy

Obviously a physician is more concerned with the results of successful splenectomy than with the operation itself. Of the operative technique, therefore, I need say little except that shock in the anæmic patient may be considerable, and that a blood transfusion while the patient is on the operating table is, in my view, highly desirable. Two surgical risks are worth mentioning here. Very rarely the splenic vessels in the pedicle are abnormal in their distribution, and instead of one splenic artery and one main splenic vein, there are several. This greatly increases the surgical risks unless the surgeon is aware of it. The only other problem is due to perisplenitis and adhesions, especially to the under surface of the diaphragm, and when these are extensive fatal oozing of blood may ensue, in spite of the most careful surgical precautions. It is in these cases that the simple operation of tying the splenic pedicle, without removing the spleen itself, is to be recommended. This operation has already been carried out with success, and a simple atrophy of the spleen results.

The most frequent and serious post-operative risk is thrombosis of veins, and no operation on the spleen should be attempted when the blood-platelet count is much above the normal 300,000 per c.mm. Following splenectomy the platelet count tends to rise, and if it reaches 700,000 per c.mm. or more the possibility of thrombosis in any vein, but particularly in intra-abdominal veins, at once arises. The thrombosis, if extensive, may be fatal in itself, or lead to hæmorrhage from increased pressure in neighbouring veins.

SPECIAL ARTICLES

MEDICINE AND THE LAW

"Psychic Pain"

INJURY entitling a workman to compensation need not be physical and visible injury. In a recent Manchester case a porter, while moving a bale of cloth weighing about 50 lb., had fallen and strained his back nearly a year ago. He was in bed for three weeks and then attended hospital until December. He complained of great stiffness in the lower part of the back; he walked in a very bent position and very stiffly and always used a stick. Examination disclosed no injury; X ray photographs showed a completely normal condition. The employers refused to pay compensation after Nov. 18th. The workman asked the court to order renewal. A medical witness, called by the employers, said he thought the workman had made up his mind he would never get better; the man himself was the greatest obstacle to recovery; he had got the habit of expecting pain whenever he moved his limbs; it was a "psychic" pain. The judge said there had been a persistent complaint of pain and there was no accusation of malingering; the "psychic" pain was the result of a physical pain, and the physical pain was the result of the accident in the course of the man's employment. An order was made for compensation from the date of discontinuance last November.

It is nowadays too late to contend that a workman cannot have compensation if his disability is due merely to the state of his nerves or to his loss of will-power. In another recent case, heard at Langport county court in Somersetshire, a gardener had slipped on some stone steps while carrying two buckets and had received injury to his back and ribs. When the visible effects had disappeared the workman still complained of pain and loss of sleep. His doctor advised him to try light work in his garden. The man found he could pull up a few weeds but could do no digging. The Medical Referee, acting as assessor, advised the court that it was a case of true neurosis. No fracture was shown by the X ray photographs. The physical disability had passed off, but the fact that the man had both the accident and the pain seemed to make him quite honestly associate the one with the other. The Medical Referee thought the pain would gradually disappear. The man ought to put in as much work as he could in his garden; if he did so, he ought not to suffer at all in three months' time. The judge held that the man was suffering from a nervous result of the accident which, so long as it existed, incapacitated him from work. "I think he has within his own command the power to cure himself; he has no need to wait till some sympathetic employer finds him

(Continued from previous page)

Just as in hepatic cirrhosis of the ordinary kind, hæmatemesis from rupture of veins in the wall of the stomach, or in the œsophagus, is by no means infrequent in cases of chronic splenomegaly, quite apart from operation. It must be stated that splenectomy does not entirely remove this risk, and that hæmatemesis has been known to occur at intervals for years after successful splenectomy.

J. W. MCNEE, M.D., D.Sc., F.R.C.P.,
Physician to University College Hospital.

a suitable job. He has a garden in which he can do the exact work which will prove his cure." The workman was entitled to compensation and a lump-sum payment of £50 was offered and accepted in settlement. The court thus went as far as it could in the direction of advising the man to take up work again. There are decisions which prevent a court from reducing the award of compensation (in the absence of misconduct) in order to put pressure upon a workman to exercise his will-power and to tackle a job of work once more.

Damages against Dentist

At Chester assizes last week substantial damages were awarded against a dental surgeon in respect of injuries sustained by reason of a tooth passing down the patient's throat after extraction and entering the lung. There was evidence that the method of plugging the patient's mouth was satisfactory and that the teeth were counted immediately after the operation. One tooth was then said to be missing and it was found in the lower jaw. Apparently the count was incomplete. Mr. Justice Lawrence had to consider the relative responsibility of dentist and anaesthetist. He held it to be the duty of the dentist to see that the pack used was a proper pack and one which would prevent a foreign body from passing down the patient's throat. The patient was afterwards seriously ill and eventually coughed the tooth out of the lung. He was now well, but he had suffered displacement of the heart, and his lungs had become hardened and deteriorated. A verdict of £800 damages, with special damages of £280, was awarded.

Fall on Polished Floor

Last July Mrs. Weigall was awarded £2826 damages in Mr. Justice Horridge's court against the Governors of Westminster Hospital for injuries sustained through a mat slipping on a polished floor in the hospital's annexe at Fitzjohn's-avenue, Hampstead. She had been to the premises to visit her son who was a patient. Having seen him, she went into another room to interview the consulting surgeon about him. She said she put her foot on a mat near the fireplace and, the mat suddenly slipping on the highly polished linoleum, she fell and broke her thigh. Her left leg was now an inch shorter than the right. The judge held, last July, that the hospital authorities ought to have known that there was unusual danger in placing the mat unsecured on a highly polished floor; there had been a failure of duty towards the plaintiff; she had not been guilty of any contributory negligence. At the trial in July Mrs. Weigall admitted in evidence that in 1911 all the toes of both her feet were amputated except her big toes; but she denied that on this account she was the less able to keep her balance. The defendants had sought to explain her fall as due to a sheer accident for which they were not responsible. The legal position depended upon the plaintiff's right to be there. Was she invited to be in the place where she met with the accident, or was she merely there at her own risk?

The Court of Appeal dismissed the Westminster Hospital's appeal last week. Two judges held that Mrs. Weigall was an invitee. She was visiting the hospital on an express or an implied invitation. Her son was undergoing treatment; she was paying a fee to the hospital and also to the consulting surgeon; there was a contract under which she had an implied

right to visit her son and to consult the surgeon about him. The hospital was therefore under a duty to take reasonable care to make the premises safe and to prevent danger of which it knew or ought to have known. One member of the court, Mr. Justice Eve, expressed the view that Mrs. Weigall was a mere licensee and not an invitee. The opinion of the majority holds the field.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE THIRD STAGE OF LABOUR

At last week's meeting of the Edinburgh Obstetrical Society Dr. Chalmers Fahmy read a communication on the management of the third stage of labour. After speaking of the normal mechanism of placental separation, he made a strong plea for allowing the third stage to take place spontaneously and without any interference. In the great majority of cases, he pointed out, the placenta separates without difficulty in less than an hour, and even if separation is delayed for two hours or so, there is seldom much bleeding if the uterus is not manipulated. He emphasised the dangers of prematurely employing Credé's method of expression: the uterus should be left entirely alone until the signs are clear that the placenta has separated, and not until these signs are present should any attempt be made to deliver the placenta, even though the third stage lasts two hours or more. Hæmorrhage in this stage is common if early manipulation of the uterus is practised; it is uncommon if nature is allowed to take its course. The indications for expressing the placenta from the uterus are hæmorrhage, and a placenta delayed for many hours. That expression should always be attempted after 50-60 minutes is a view held by many, but Dr. Fahmy believes this plan to be unwise. A placenta which is adherent at the end of an hour, he said, might not be adherent at the end of the second or third hour. If Credé's method fails, there is hæmorrhage to a degree which leads immediately to manual removal. Experiences were cited showing the safety of leaving the placenta in utero for some hours when the patient can be kept under observation by the nurse or doctor. Many examples were given of patients with "adherent placenta" being sent to hospital after frequent attempts by Credé's manœuvre had failed. Such patients were generally shocked and had bled freely as the result of the attempts; as a rule, the treatment adopted in hospital had been one of rest by morphia. The placenta was usually found in the vagina some hours later.

Dr. Fahmy disagreed with the statement, often made, that the mere retention of the placenta frequently causes shock; such a development was rare. Laceration of tissues and frequent attempts at Credé's expression were the common causes of shock in the third stage. He stated his belief that the early adoption of methods to express the placenta was the cause of much postpartum and third-stage hæmorrhage; such would seldom be seen if more patience were exercised after the delivery of the child, whether the delivery had been spontaneous or instrumental. Manual removal of the placenta either at home or in hospital should be avoided if at all possible; if the placenta were left to separate spontaneously, the need for such interference would seldom arise. A policy of patience that is advocated by all for the second stage of labour should be upheld during the third stage also.

PARIS

(FROM OUR OWN CORRESPONDENT)

LES CAUSES PRINCIPALES DU MALAISE MÉDICAL

WHILE most of us get no further in our diagnosis of the present *malaise médical* than to the generalisation that there is something rotten in the State of Denmark, the biologist, Auguste Lumière, has taken us a step onwards by quoting certain illuminating statistics. One reason why the general practitioner now sits twiddling his thumbs for lack of a more constructive occupation is that crowds of potential patients, tuberculous or conceivably tuberculous, now attend tuberculosis dispensaries or take refuge in sanatoriums, preventoriums, and allied institutions. In 1934 there were 834 dispensaries in which more than a million and a half visits were paid. Of the 890,056 persons presenting themselves at these dispensaries in this year, only 335,199 were found to be tuberculous. Further, in the same year, 1,221,955 visits were paid in the patients' homes by visiting nurses. Institutions of the sanatorium class provided 72,561 beds.

Other statistics, produced by the *Phare Médical de Paris* for January, reveals a big leakage of the general practitioner's sources of revenue in quite a different quarter. In 1920 the number of days spent in the hospitals of Paris was 1 million. In 1933 this number had risen to 13 millions—an average increase of 1 million per year. It has been calculated that about half these hospital patients are paid for by the national insurance scheme out of accident insurance funds, or are able to pay out of their own pockets. If the cost of each day in hospital is some 40 francs, it will be seen that the total sum the taxpayers have to contribute towards the treatment of the sick members of the community is thumping big. It is, however, an ill-wind that blows nobody any good, and though the taxpayer bleeds and the general practitioner starves, the sick themselves are almost to be envied.

EUTHANASIA

On Feb. 6th Dr. Thierry de Martel, the brain specialist and chief surgeon to the American Hospital in Paris, was the guest of honour at the weekly lunch of the American Club. He said that euthanasia had many defenders, but was not yet accepted by the legislature of any country. Might not the day come, he asked, when the doctor would be permitted to give death painlessly, and even agreeably, to the sick who asked for it? Even if euthanasia was to become legal, he did not think its benefits would be as often sought as was commonly supposed, for, in his opinion, men cling to life, no matter how little of it remains to them or how painful it may be. Only once in the course of his career had a patient been sincere in his request for death.

THE HIPPOCRATIC OATH FOR DOCTORS OF MEDICINE

Two French universities have recently decided to require the Hippocratic Oath of medical students before they graduate in medicine. The faculty of medicine of Bordeaux adopted this measure from Jan. 1st, 1936. The text of the Oath must be printed at the end of each thesis, and when it is defended, the candidate must read the Oath standing before the jury. The French faculties of medicine which now require the Hippocratic Oath of candidates in medicine are those of Paris, Nancy, Strasbourg, Bordeaux, Montpellier, Marseilles, and Algiers.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

AN ENEMY OF QUACKS

THE American Medical Association announces that Dr. Arthur J. Cramp is retiring after thirty years' service at its headquarters. Born in London in 1872 the first child in a large family, he was educated at Sir Walter St. Johns and became junior clerk in a London steamship office; but at the age of 19 he abandoned that path of fame and emigrated to the United States. After an American college education he became a teacher and occupied his spare time in contributing a weekly newspaper column. He graduated from the Wisconsin College of Physicians and Surgeons in 1906, and after a brief experience of medical practice became attached to the staff of the *Journal of the American Medical Association*. Very soon after that he developed what was first called the Propaganda and Reform department and is now known as the Bureau of Investigation. The two volumes "Nostrums and Quackery" represent only a small part of his efforts in this field. His office has investigated over 200,000 quacks and quack remedies and maintains a complete file of the records from which information is supplied daily to federal and State health officials, educational institutions of all kinds, editors of magazines and newspapers, and the less easily bamboozled members of the general public who prefer not to swallow every remedy that is baited with a testimonial.

The work will go on, but to those of us who have known it throughout many years the Bureau will never be the same without its genial, courteous, passionately efficient director. Some of his many friends will dare to expect that even in retirement in his new Florida home he will continue to wield his effective pen. A third volume of "Nostrums and Quackery" is badly needed!

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. A. G. Taylor to *Drake* for R.N. Hospital, Plymouth; T. J. O'Riordan and R. J. Inman to *Drake* for R.N.B.; H. L. P. Peregrine to *Osprey*.

Surg. Lt. Comdrs. G. Rorison and L. J. Corbett to *Shropshire*.

Surg. Lt. Comdr. L. Lockwood, M.V.O. (Royal Australian Navy), to *President* for course.

Surg. Lts. H. G. Silvester to *Kempensfelt*, A. J. Glazebrook to *Arethusa*, and W. J. F. Guild and J. G. Slimon to *President* for course.

E. R. Sorley, J. M. Sloane, T. F. Crean, W. P. E. McIntyre, E. T. S. Rudd, E. H. Rampling, E. E. Malone, L. P. Spero, and C. B. Nicholson to *President* for course.

The following have been appointed Admiralty Surgeons and Agents: Weston-super-Mare, Mr. E. R. Clutterbuck; Coventry, Surg. Lt. Comdr. W. P. Elford, R.N.V.R.; Newquay, Mr. D. R. Mitchell; Enfield Lock, Mr. H. P. Warren; Guernsey, C.I., Surg. Lt. Comdr. B. S. Collings, R.N. (retired); Emsworth, Hants, Surg. Capt. H. P. Turnbull, R.N. (retired); and Haslemere, Mr. C. W. Jenner.

ROYAL NAVAL VOLUNTEER RESERVE

Proby, Surg. Sub-Lt. R. R. Prever promoted to Proby, Surg. Lt.

ROYAL ARMY MEDICAL CORPS

Temp. Commissions.—The undermentioned to be Lts.: C. W. Maisey, Maj. G. M. Lewis, from R.A.M.C. (T.A.),

and relinquishes the rank of Maj., H. Ferguson, A. T. Marrable, R. J. G. Morrison, and F. T. Moore.

REGULAR ARMY RESERVE OF OFFICERS

The undermentioned having attained the age limit of liability to recall cease to belong to the Res. of Off.: Lt. Cols. W. J. E. Bell, D.S.O., F. T. Dowling, and G. R. Painton, and Maj. T. W. O. Sexton.

TERRITORIAL ARMY

Capt. R. Lodge resigns his commn.

Capt. A. J. Will to be Maj.

V. H. Sarland (late Lt., I.M.S.) to be Capt.

K. M. Morris (late Offr. Cadet, Edinburgh Univ. Contgt. (Med. Unit), Sen. Div., O.T.C.) to be Lt.

ROYAL AIR FORCE

Flight Lt. F. E. Lipscomb to R.A.F. Station, Northolt.

INDIAN MEDICAL SERVICE

Maj. J. E. Ainsley to be Lt.-Col.

Military Cross.—Temp. Capt. Patit Paban Chowdry, M.B., B.S., late I.M.S., for distinguished services rendered in the field in connexion with the Loe-Agra Operations, N.-W. Frontier of India, Feb. 23rd to April 13th, 1935.

The names of the following have been brought to notice by the Commander-in-Chief in India, for distinguished services rendered in connexion with the operations:—

I.M.S.: Maj. A. H. Craig, M.B., Ch.B., No. 3 Field Ambulance; T/Capt. P. P. Chowdry, M.B., B.S.; T/Capt. S. P. Bhatia, M.B., B.S., M.R.C.S.

INDIAN HOSPITAL CORPS: No. 1/A/3451 Naik Guahar Singh, No. 3 Field Ambulance.

The undermentioned officers have vacated appts. in India:—

D.D.M.S.—Maj.-Gen. J. F. Martin, C.B., C.M.G., C.B.E., K.H.S., Brit. Serv.

A.D.M.S.—Maj.-Gen. A. W. M. Harvey, K.H.S., I.M.S.

D.A.D.H.—Maj. J. W. F. Albuquerque, I.M.S.

The undermentioned appts. have been made in India:—
D.D.M.S.—Maj.-Gen. A. W. M. Harvey, K.H.S., I.M.S.

Maj.-Gen. G. A. D. Harvey, C.M.G., Brit. Serv.

COLONIAL MEDICAL SERVICE

Dr. W. Barnetson has been appointed Medical Officer, Uganda, and Dr. G. L. Timms, Medical Officer, Kenya.

DEATHS IN THE SERVICES

The death occurred on Feb. 17th at Plymouth of Lieut.-Col. THOMAS HERBERT CORKERY, R.A.M.C. ret'd. He was born at Poona in 1861, and qualified in 1884 with the Scottish double diploma. He joined the Army as a surgeon in January, 1886, accompanied the expedition to Manipur in 1891, receiving a medal with clasp. He also served in Burma 1891-92, and with the expedition to Kachin Hills, for which he received a clasp. On retiring from the active list in 1906 with the rank of lieut.-colonel he was employed at Exeter until 1911, and three years later was recalled to service during the European war.

THE American Academy of Arts and Sciences announces that the first award of the Francis Amory septennial prize, which is offered for contributions of "extraordinary or exceptional merit" to our knowledge of the diseases of the human generative organs, will be made in 1940 if work of sufficient merit is put forward. The total amount of the prize will exceed ten thousand dollars, and it may be given in one or more awards. There will be no formal nominations and no essay or treatise will be required; but the committee invites suggestions, and these should be sent to the Academy at 28, Newbury-street, Boston, U.S.A.

CORRESPONDENCE

MEDIASTINOTOMY FOR SURGICAL EMPHYSEMA

To the Editor of THE LANCET

SIR,—Generalised surgical emphysema may or may not be a clinical rarity when associated with pulmonary tuberculosis, as in the case reported in your current issue. It may, however, be a fatal condition when it complicates either disease or injury. The fact that such cases may be saved by the early performance of the (almost minor) operation of suprasternal (collar) mediastinotomy does not, strangely enough, seem to be generally appreciated, even amongst surgeons. A simple incision, immediately above the sternum, down to and through the deep fascia, allows the air, often pent up under considerable tension, to escape freely. The operation may be done with the patient in bed, and, if not withheld too long, the way in which a hitherto generalised emphysema will subside within a few hours can only be described as dramatic.

I am, Sir, yours faithfully,

GEORGE A. MASON.

Newcastle-upon-Tyne, Feb. 17th.

CHILD BORN WITH A FOREIGN BODY IN THE HEART

To the Editor of THE LANCET

SIR,—Drs. Eaton and Corbet, having found at autopsy a small metallic foreign body in the right ventricle of a new-born child's heart, suggest with assurance that the object must have been within the uterus at the time of conception, and that the embryo "grew around it." Although gold and silver intra-uterine contraceptives may fail in their purpose and appear as neonatal decorations, it is difficult to see how this particular foreign body, which was 3 by 2 mm., came to be lying free within the right ventricle of what we take to be an otherwise normal heart, if we have to rely on your correspondents' suggestion that the embryo must have virtually wrapped itself around the object. The heart is already well developed though tubular after 26 days or so, at which time the whole embryo would only be of the size of the foreign body! One cannot imagine inclusion of such a body and the subsequent development of anything like a normal foetus. Surely a more reasonable explanation is that the object, lying within the uterus, was involved between true and capsular decidua and thus came to be incorporated in the blood sinuses of the placenta, whence it became dislodged, probably during the commotion of labour, and passed via umbilical vein to the right heart.

I am, Sir, yours faithfully,

Guy's Hospital, S.E., Feb. 17th.

J. R. AUDY.

TRANSMISSION OF RELAPSING FEVER BY TICKS IN PALESTINE

To the Editor of THE LANCET

SIR,—It has been suspected since the late war that there is a relapsing fever in Palestine transmitted by ticks. The fowl tick, *Argas persicus*, which is widely disseminated in Palestine, has been wrongly suspected. Recent investigation of a small outbreak of relapsing fever in Kfar Vitkin, south of Hedera in the coastal plain, showed that all infections could be traced to a cave infested with *Ornithodoros papillipes*.

Ticks collected in the cave readily transmitted spirochaetes to rats in the laboratory. This tick produces a local analgesia while biting and there is therefore no reaction (scratching) on the part of the victim. Coxal fluid and faeces are not excreted during feeding. Transmission is therefore obviously by bite, and contamination plays no part. The entry of spirochaetes into the skin from the proboscis of infected ticks was demonstrated experimentally. Three infected ticks (adults) were fed on a human being during an intermission between two relapses; immediately after feeding the puncture wounds were examined and spirochaetes demonstrated in smears stained with Giemsa. A similar experiment performed on a clean rat gave an identical result; spirochaetes were easily demonstrated in the smears and the rat subsequently became infected.

We are, Sir, yours faithfully,

S. ADLER, O. THEODOR,
H. SCHIEBER.

Jerusalem, Jan. 29th.

PURIFICATION OF THE HEMOPOIETIC FACTOR

To the Editor of THE LANCET

SIR,—In your annotation last week there is a slight misunderstanding as to the "maximally effective dose" of Dakin and West's liver fraction. A single dose which is effective for the production of maximal reticulocyte responses is not necessarily sufficient to produce an increase of red blood-cells at a maximum rate over periods of from 10 to 20 days or more. It is therefore incorrect to compare the single doses of 80–150 mg., which in Dakin and West's series usually produced maximal reticulocyte responses, with the average amount (359 mg.) which, given in divided doses to 11 of our cases, was followed by a certain average rate of red blood-cell increase in 40 days, since, in the former series, data regarding the red blood-cell increases following the reticulocyte crises are not available. A comparison of reticulocyte responses following single doses of material is given in Table II. of our paper, and the conclusion is that for the production of maximal reticulocyte responses single doses in excess of 100–200 mg. are usually required.—We are, Sir, yours faithfully,

C. C. UNGLEY, E. J. WAYNE,
L. S. P. DAVIDSON.

Newcastle-upon-Tyne, Feb. 14th.

HOSPITALS AND THE RATES

To the Editor of THE LANCET

SIR,—My attention has been drawn to a serious inaccuracy in a statement on the rating of hospitals made to our last court of governors. In a comment upon the wide variation in assessments throughout the country the Newcastle hospitals were cited as among those either not rated or subsidised by municipal authorities. This is not the case. My board regret that this unfortunate slip has caused trouble to the management of the Royal Victoria Infirmary, and would be grateful if you would publish this correction.

I am, Sir, yours faithfully,

S. R. C. PLIMSOLL,

Secretary-Superintendent, The Middlesex Hospital, W.1.
Feb. 18th.

STAMMERING NOT A SPEECH DEFECT

Miss KATE EMIL-BEHNKE writes: "I have read with great interest the annotation on this subject in your issue of Jan. 25th (p. 208). If the dictum 'Define your Terms' had been acted upon in the past in the consideration of stammering the fatal error would not have been made of regarding it as a defect of speech. By 'defect' is generally understood a permanent disability, which in its application to speech indicates an ever-present inability to articulate some letter correctly, such as lisping, whereas there is no letter that a stammerer cannot at times enunciate perfectly. Curiously enough, this very variability in its incidence has contributed to the misconception as to the true nature of the trouble, leading to two assumptions both of which prevent treatment being undertaken in the early stages, when it can be speedily and permanently overcome. One assumption is that the trouble will be outgrown, a view which is encouraged by the fact that as stammerers grow older they become adroit at evading words which present a difficulty and substituting others. The second assumption is that the stammer is due to carelessness, the latter idea being very naturally fostered by there being many occasions on which no stammering is present.

"Undoubtedly stammering is in essence a neuro-pathic condition, and suitable treatment should be applied directly there is any sign of it, when it will yield to psychic handling combined with 'relaxing' and quiet deep breathing exercises. If the trouble is not attended to derangement of the entire musculature of respiration, phonation, and articulation follows, leading not only to the establishment of the 'fear' complex but to wrong muscle action, both of which can, later, only be conquered at the cost of considerable expense, time, and patience. The resultant derangement is so great and so obvious that it has led to the serious error of adopting *elocutionary* treatment which is not only useless, but in the majority of cases makes the trouble far worse by focusing the stammerer's attention on symptoms and not on the cause.

"It was formerly held that it was useless to attempt treatment before the age of ten. Present-day knowledge enables it to be applied as early as three or four years of age—in other words, when the trouble first appears."

THE GRINSTEAD SERPENT

"ALBUS" writes: "Objections have been made to the symbol of the serpent surmounting the Grinstead Hospital, as it has been held to be the symbol of evil. It is true that the serpent is introduced into the story of the Fall as the symbol of evil united with wisdom, because it was under this form that he beguiled Eve. Revelation xii. 9, states: 'And the great dragon was cast down, the old serpent, he that is called the Devil and Satan, the deceiver of the whole world.' Serpents were early recognised to be dangerous and the idea arose to escape evil by propitiating the power that was behind it; hence serpent worship, a form of superstition widely spread. Good qualities were then attributed to the object of worship, especially the power of healing; this may have determined the display of a brazen serpent as the means of curing the snake-bitten Israelites. Large snakes were usually kept in the shrines of Æsculapius and appear sometimes to have been regarded as the God himself; patients in the shrines had visions in which some action is taken by snakes or dogs. The snakes thus seen in dreams were connected with healing and not evil.

"Superstition has clustered round snakes. The snake has been regarded as a symbol of hygiene

because he shed his skin so frequently while renewing his health. The snake is also a symbol of eternal life in the form of a living ring when the snake has his tail in his mouth. In Hindu mythology, said Monier-Williams, the Sanskrit scholar, a curious race of serpents, half human, half divine, called Nagas, is supposed to exist in the regions under the earth.

"The caduceus is a subject of controversy. It has been used as a medical emblem in, for example, the French military corps, our own R.A.M.C., and the arms of Dr. Caius, the second founder of Gonville and Caius College. The usual emblem employed is a staff around which two serpents are interlaced, though one serpent only is occasionally present as in the R.A.M.C. emblem. The medical connexion of course is that the device is accepted as the sign manual of Æsculapius, although the original emblem of Æsculapius was a club with one serpent coiled round it, symbolising the snake's power of renewal. The staff with two serpents coiled round it was not connected with medicine originally. It was the device borne by the messengers of the gods, especially Mercury; in its original form the staff was surmounted with a knot of ribbons for which later two intertwined snakes were substituted. As however no existing activities are represented by the action of the messengers of the Gods in conducting souls to the world below, the staff, now with intertwined serpents, has come to stand for the art of medicine. The application of the term caduceus or wand of Mercury to the staff and serpent of Epidaurus which symbolises Æsculapius is therefore erroneous. There is a more commonplace and humorous interpretation of the rod with its interlaced snakes; it has been held to signify concord between merchants in competition; the serpent has always symbolised astuteness, eloquence, and seductiveness, qualities in keeping with this commercial interpretation of the caduceus." A fine large example of the wand can be seen on the new metal outer door of the Bank of England.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED
FEB. 8TH, 1936

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2270; diphtheria, 1370; enteric fever, 23; acute pneumonia (primary or influenzal), 1472; puerperal fever, 44; puerperal pyrexia, 132; cerebrospinal fever, 17; acute poliomyelitis, 2; acute poliomyelitis, 1; encephalitis lethargica, 6; dysentery, 32; ophthalmia neonatorum, 82. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Feb. 14th was 4257, which included: Scarlet fever, 1012; diphtheria, 1094; measles, 816; whooping-cough, 697; puerperal fever, 19 mothers (plus 14 babies); encephalitis lethargica, 283; poliomyelitis, 3. At St. Margaret's Hospital there were 20 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 54 (5) from measles, 7 (0) from scarlet fever, 28 (10) from whooping-cough, 39 (4) from diphtheria, 45 (24) from diarrhoea and enteritis under two years, and 85 (11) from influenza. The figures in parentheses are those for London itself.

The mortality from influenza is on the wane, the total deaths for the last ten weeks, working backwards, being 85, 98, 104, 89, 110, 110, 80, 67, 62, 45. The deaths this week are scattered over 44 great towns, Bristol reporting 5, Manchester and Birmingham each 4, Halifax, Liverpool, St. Helens, Sheffield, and Stoke-on-Trent each 3, no other great town more than 2. Manchester had 10 deaths from measles, Liverpool 7, Salford and Bristol each 4. Whooping-cough caused 5 deaths at Birmingham. Deaths from diphtheria were reported from 25 great towns, 4 from Hull, 3 from Newcastle-on-Tyne, 2 each from Wood Green, Reading, Middlesbrough, St. Helens, Salford, Wakefield, and Swansea.

The number of stillbirths notified during the week was 272 (corresponding to a rate of 40 per 1000 total births), including 38 in London.

OBITUARY

**SIR CHARLES BALLANCE, K.C.M.G., C.B.,
M.S. Lond., F.R.C.S. Eng.**

CONSULTING SURGEON, ST. THOMAS'S HOSPITAL

THE death occurred, as we announced last week, on Saturday, Feb. 8th, of Sir Charles Ballance, the distinguished surgeon and neurologist, consulting surgeon to St. Thomas's Hospital. He had been in delicate health for some time, though his final illness was not a long one.

Charles Alfred Ballance was the eldest son of the late Charles Ballance, of Stanley House, Clapton. The father died in 1873 leaving four sons and four daughters, the eldest son being only 17 at the time. The family had lived in Taunton previous to migration to London, and Charles Ballance went to Taunton College and for a period on the continent for his early education before entering St. Thomas's Hospital as a student. It is an interesting fact that the three younger brothers followed their senior's example in the choice of a profession, the surviving one being Sir Hamilton Ballance.

Ballance entered St. Thomas's Hospital in 1876 and was from the first a distinguished student. He took the English diplomas in 1879, and in 1881 graduated as M.B. Lond. with first-class honours in each subject, and B.S. as gold medallist. In the following year he obtained the diploma of F.R.C.S. Eng. and the degree of M.S., when he was again gold medallist. At St. Thomas's he filled a series of resident posts, becoming later surgical registrar to the hospital and demonstrator of anatomy. He spent the time of waiting in anatomical and bacteriological research in London and in Leipzig, where he attended the first bacteriological course opened in the university, a veteran experience to which he would often allude. His first staff appointment at St. Thomas's came promptly—it was that of assistant aural surgeon, and in the same year he was elected assistant surgeon to the West London Hospital. He was also appointed examiner in elementary anatomy at the Royal College of Surgeons of England where he delivered in 1889 the Erasmus Wilson Lecture on the ligation of arteries. This lecture indicated the direction which Ballance's first original researches had taken, and in our columns last week Sir Charles Sherrington described graphically the intensity with which Ballance and Walter Edmunds worked out their valuable and practical conclusions. These researches were followed up by the eager quest with S. G. Shattock for parasitic protozoa, hoping thus to

determine the aetiology of malignant disease. As is known, despite the elaborate pains and time expended, no conclusive results were reached.

But Ballance became known to the surgical world as a coming man, and to this position he was aided by his writings. He contributed to Heath's "Dictionary of Surgery" the article on meningocele and encephalocele, and that on injuries and diseases of the scalp; in the *Transactions* of the Pathological Society he wrote, in association with Shattock, on the intimate pathology of cancer; to the *Journal of Physiology* he contributed in collaboration with Sherrington a paper on the genesis of scar tissue; while other papers, all the result of personal investigation, appeared in the *Transactions* of the Medical Society,

of the Clinical Society, and frequently in the *St. Thomas's Hospital Reports*. The Erasmus Wilson Lecture became the foundation of a book written in collaboration with Edmunds, who was the first medical superintendent of St. Thomas's Home—an excellent surgeon and a keen experimental investigator. The joint work proved that the results up to that day of operations upon great arteries were unsatisfactory, the danger of secondary hæmorrhage being a pressing one, and the authors set out to show how such failures came about and how they could be avoided. An elaborate series of experiments continued over six years was detailed in the treatise. Ballance wrote also soundly on various directions of aural practice in Allbutt's "System of Medicine" and in the *St. Thomas's Hospital Reports*, and in the *Transactions* of the Medical Society of London and those of the Medico-Chirurgical Society. In 1891 Ballance was appointed surgeon to the National Hospital for Paralysis and Epilepsy where he worked with Victor Horsley with whom he had previously been associated at the Browne Institute during Horsley's superintendency. His claims to the appointment were strong.

Ballance's experiments on nerve-suture and nerve-grafting were elaborate. On this work he was engaged for many years, in collaboration with Sir James Purves-Stewart, the publication of the results being however delayed by Ballance's absence at the South African war. They appeared at last in 1902 in an illustrated quarto volume in which the experiments were fully described, the process of degeneration in the peripheral nerve after injury and of regeneration in a divided nerve being carefully set out, while a good historical résumé and bibliography were appended. The experimental work was

SIR CHARLES BALLANCE

(Photograph by Elliott & Fry)

afterwards explained by the authors at a meeting of the Royal Medico-Chirurgical Society, where in the discussion which took place Sherrington, Mott, Rickman Godlee, and other experts debated at length the conclusions of the authors, which were found to be of high practical value.

In a large number of public deliveries Ballance throughout his career informed his hearers of neurological progress and of the methods employed by himself and those with whom he worked. Such an address was delivered at Brighton in 1907 when he gave a vivid account of his personal experiences in cranial surgery. Comparing the indications for opening the abdomen with those for opening the skull, he pointed out that the diagnosis of intracranial disease is the far more complex problem, while exploratory operation cannot be conducted with the same rapidity and completeness. Thus he found the maxim that diagnosis should precede operation to be true *only* of those diseases where the signs, symptoms, and course can be fully comprehended; where danger will attend delay provisional diagnosis must be acted upon, while the most eminent neurologists will occasionally differ as to the localisation of a brain tumour. He recorded cases where intracranial intervention had been called for by the obvious conditions found, and paid a tribute to the value of X ray photography at the stage which it had reached 30 years ago. The address was a good example of the speaker's power, frequently displayed, of dealing with large subjects clearly and succinctly, a faculty which he kept throughout his life—instances, the Lister Memorial Lecture, the MacEwen Memorial Lecture delivered in 1930 at Glasgow where the university conferred upon him the LL.D. degree, and the address on the progress of surgery delivered in 1906, as president of the Medical Society of London.

Ballance's contributions to medical literature, if published in volume form, would have shown him a prolific author, but although he might have constructed many books by compilation, only two stand to his individual name—viz., "Points in the Surgery of the Brain and Membranes," and "Essays on the Surgery of the Temporal Bone." The latter, published in 1919, was a massive production, for the subject was dealt with in two large volumes, while the format and illustrations compelled its issue at a very high price. The valuable display of plates offered a possible substitute for study in the museum and post-mortem room, while the text was erudite, the result of ripe experience and high literary capacity. The volumes traversed the history of the surgery of the temporal bone and described in detail the intracranial complications of the pathology of the region. The book was written as a plea for the better recognition of the importance of aural surgery and the provision of additional beds for aural patients.

Ballance had important and intimate relations with the Royal College of Surgeons of England. The Erasmus Wilson Lecture he delivered shortly after he obtained the Fellowship, while early in his career he was appointed an examiner in anatomy. And at this end of his life he was working at the laboratories of the College at Down with undiminished interest in neurological research. He was elected to the council of the College in 1910, was a member of the court of examiners for ten years, and of the council for 16 years, becoming in 1920 vice-president of the College. In 1919 he delivered the Bradshaw Lecture upon surgery of the heart (THE

LANCET, i., 1, 73, and 134), in 1921 the Thomas Vicary Lecture on the history of surgery of the brain (THE LANCET, 1922, i., 111, 165), and in 1933 delivered the Lister Memorial Lecture, in which he showed that his early investigation into the cause of malignant disease was still vivid in his mind. In the address he described the work done with Shattock on the appearance of incubated carcinomatous cells, to which Sir Charles Sherrington referred last week, and on this occasion the Lister medal was conferred on him for his distinguished contributions to surgical science, an honour shared with his friends Harvey Cushing and Watson Cheyne.

Ballance had worked with Cushing on more than one occasion in America; latterly he spent a long period in the States where full opportunities for experimental work were afforded him, and where his position as a neurologist stood very high. Unfortunately this visit coincided with the sudden and acute dislocation of financial affairs in the United States, and although Ballance worked with his usual thoroughness, his physiological experiments were necessarily impeded for want of material.

Ballance was the first president of the Society of British Neurological Surgeons. "He founded the society," says Mr. Geoffrey Jefferson, "but characteristically refused to hold office for more than one year, insisting on relinquishing office for Mr. Wilfrid Trotter. The society replied by making him honorary president." Mr. Jefferson also writes in admiration of Ballance's enthusiasm maintained to the end of his life for the fields of investigation which he had cultivated. "He was," he says, "a regular attendant at meetings, and at the age of 77 he journeyed to Edinburgh and Aberdeen to show his films of experimental nerve anastomosis; and later to Manchester. He belonged to an age in neuro-surgery which is past, and his chief value in discussion was his reminiscence of famous happenings of bygone days. Nevertheless his comments on current trends and events were always most trenchant, and though he admired the past his wits were definitely in the present. He endeared himself to us all by his friendliness, his encouragement, and the genial banter of his conversation." Prof. Archibald Young writes in similar vein of "the generous readiness and enthusiasm with which Ballance received new work by a junior colleague. In the deliberations of the Society of British Neurological Surgeons his searching but kindly criticism was always welcomed. In spite of advancing years he remained very much the young man, and in his latest years did some of his most remarkable work on nerve anastomosis and regeneration."

Ballance had a distinguished war record. He was called up on the outbreak of hostilities with the rank of colonel, A.M.S., and did valuable service in the Mediterranean during the war years, stationed in Malta. He was several times mentioned in dispatches, and in 1916 was made C.B. (Mil.). The University of Malta gave him a medical degree. In 1918 he was made K.C.M.G.

We have here a picture of a singularly consistent career. Ballance vowed himself to surgery almost as a boy, and never deviated from the obligations. In the ward and in the operating room, as in the laboratory, he was single-hearted in his search for the truth. He was a man of wide reading, as would appear from the quotations in his numerous addresses, but in everything that he wrote he kept the same unswerving path, the same determination to advance medical knowledge by the records of experiment and observation.

Sir Charles Ballance married in 1883 Sophia Annie, daughter of the late Alfred Smart, of Blackheath, who died ten years ago. They had one son and several daughters, but the son, Dr. Alaric Ballance, to his father's intense grief, died quite young in 1932.

ADOLPH BRONNER, M.D. Heidelb., M.R.C.S. Eng.

THE death occurred on Feb. 7th at the age of 75 of Dr. Adolph Bronner, well known as ophthalmologist and laryngologist. He was a profuse contributor both to English and foreign journals on his specialties, and his work at Bradford earned him a wide reputation.

Adolph Bronner was born in 1860 the younger son of the late Dr. Edward Bronner, who founded, in coöperation with the late Dr. John Bell, and with the financial assistance of Sir Jacob Behrens, the Bradford Royal Eye and Ear Hospital. He was educated at Bradford High School and Bradford Grammar School, receiving his medical training at the universities of London, Heidelberg, Freiburg, and Berlin. He graduated at Heidelberg as M.D. in 1884 and in the following year took the diploma of M.R.C.S. The early direction of his studies was indicated by an appointment at the Royal London Ophthalmic Hospital and by an M.D. thesis on sympathetic ophthalmia. Appointed surgeon to the Bradford Eye and Ear Hospital in 1886 in succession to his father, he later became laryngologist at the Bradford Royal Infirmary. His contributions to the *Transactions* of the Ophthalmological Society covered a large range of subjects, while other papers which attracted attention will be found in the *Archives of Otolaryngology* (New York) and in the *Transactions* of the International Medical Congress at Rome of 1894 where he acted as secretary to the laryngological section, and in those of the international meetings of otologists held at Paris in 1889, Berlin in 1890, and London in 1899. To the *British Medical Journal* and to these columns he also contributed many sound and interesting clinical papers, giving always practical information.

Bronner was deservedly held in high esteem by his Bradford colleagues and was at one time president of the Bradford Medico-Chirurgical Society and at another president of the Leeds Medico-Chirurgical Society. At the time of his death he was consulting surgeon both to the Bradford Royal Eye and Ear Hospital and consulting laryngologist to the Bradford Royal Infirmary.

Prof. F. W. Eurich writes: "Dr. Adolph Bronner had retired only 13 years before his death but so great had been the changes in the professional life of Bradford that there are now not a few to whom he has been little more than a name. There will however be many former patients who remember him as their benefactor and friend and they will be widely scattered for they came not from the West Riding only but from the Yorkshire dales and neighbouring counties. After the death of his father Dr. Edward Bronner, his elder brother took the family practice, leaving Adolph Bronner to devote himself to diseases of the eye, ear, and throat. He built upon foundations laid by his father but soon made a great name for himself both among his colleagues and the public. It could not have been otherwise for he combined with deep knowledge and with great skill as an operator a cheeriness and a kindness of heart which won him the affection of all. Even in the thronged life of hospital practice he was never brusque. He would care for more than the

special trouble for which his advice was sought, and many a sovereign and even now and then a five-pound note would be passed surreptitiously to some needy patient. When he retired from hospital practice a tablet commemorating his great services was placed beneath that dedicated to the memory of his father in the entrance-hall of the Bradford Eye and Ear Hospital. A year or two later he left Bradford to enjoy his hobbies—golf and fishing, but, a bachelor, he never settled anywhere, coming back at last to die in the city he had served so well."

ALFRED SAMUEL GUBB, M.D. Paris, D.P.H.

WE regret to learn the death of Dr. Alfred Gubb, who 50 years ago was very well known to many of his London colleagues; for the last 30 years he practised on the continent, mainly in Algeria.

Alfred Gubb was born at Abingdon in 1857, the son of Edwin John Gubb, a lecturer in science. He received his medical education at the Westminster Hospital, where he was Bird prizeman and a medallist, and later at the University of Paris, where he graduated in medicine in 1885. He was appointed resident obstetric assistant to the Westminster Hospital and then for a year was resident medical officer at the French Hospital in London. He had a considerable continental connexion, held a post as medical adviser to the Belgian Consulate and for some time was English correspondent of *La Semaine Médicale*. From 1898 to 1903 he was editor of the *Medical Press and Circular*, with which journal he maintained his connexion until quite recently as a translator of articles from the French. To *The Lancet* he made occasional contributions, either in connexion with materia medica or with obstetric medicine. These subjects furnished him with the material for a useful little book "Aids to Gynæcology" and qualified him to edit Griffith's "Materia Medica and Pharmacy." More than 30 years ago Gubb decided to practise abroad and at first spent half the year in Aix-les-Bains and the remainder in Algeria. From Algeria he made from time to time interesting communications on the climate, flora, and natural features of the country. Some of those he put together into pamphlets or albums, as he elected to call them, because of their profuse illustrations, and he maintained for a period a close association with British practitioners wishing to send patients abroad. He died on Feb. 3rd at Mustapha Supérieur, Algiers.

ETHEL MILLER VERNON, M.D. Lond.

THERE died on Jan. 19th Dr. Ethel Vernon, a prominent woman practitioner who had been in general practice in Westminster for over 30 years. She was the eldest daughter of Thomas Heygate Vernon. Three members of the family entered the medical profession, the others being Dr. Horace Vernon, a well-known authority on hygiene, and Mr. Arthur Heygate Vernon, a skilful and successful surgeon at Bournemouth, whose death occurred last year.

Ethel Vernon was one of the earliest women to qualify through the London School of Medicine for Women, obtaining the L.S.A. in 1897 and four years later graduating as M.D. Lond., at that date an unusual distinction. At the London School of Medicine for Women she was demonstrator of physiology, while she acted as house surgeon and house physician at the New Hospital for Women and as assistant anaesthetist at the Royal Free Hospital.

She then went into private practice, midwifery occupying most of her time at the commencement. In this capacity she became the adviser and in many cases the personal friend of a large number of her patients, her success as family counsellor being due not only to clinical accomplishment, but to close understanding of the domestic problems which arise in households where the daily cares weigh heavily on the mother. She carried her sympathy to a high level of personal responsibility, denying herself to assist the sick mother or child and often placing her seaside home at their disposal. For over 20 years she worked hard for the promotion of child welfare, was medical adviser to the Borough-road Infant Welfare Centre, the Sutton Nursery School, and Highgate School for Girls, while since 1919 she had been medical officer to two Westminster welfare centres. She shortened her life by her devotion to her work. A woman of unusually robust constitution and physique, she remained at work throughout the recent severe cold period and succumbed unexpectedly to an attack of pneumonia. The memorial service held at St. Martin-in-the-Fields proved by the large congregation of mourners the esteem and affection in which she was widely held.

RICHARD VERNON FAVELL, M.R.C.S. Eng.

Dr. Richard Favell, who died on Feb. 4th aged 55, was a student at St. Bartholomew's Hospital, where he took the double English diploma in 1906 and held the appointments of house surgeon and resident midwifery assistant. He was also president of the Abernethian Society. He was a member of a well-known Sheffield family and at the beginning of his professional career practised in partnership with his father, Dr. Richard Favell, senior. He continued in practice at Sheffield for a time and acted as anaesthetist to the Sheffield Royal Infirmary, but retired some 12 years ago to Cornwall, living at St. Buryan, where his death occurred. In Cornwall he held many public offices, while he was a keen educationist and an accomplished archæologist and horticulturist. He had been High Sheriff for the county where he was a considerable landowner, and was an F.S.A. Scotland.

HUGH MILLER GALT, M.B. Glasg.

WE regret to announce the death on Feb. 14th, at his home in Jersey, of Dr. Hugh Galt. Born at Kilmarnock and educated at Kilmarnock Academy, he entered the University of Glasgow as a medical student, graduating as M.B., C.M. with honours in 1891 and being also a prizeman. He was for a time house surgeon and house physician at the Western Infirmary, Glasgow, and then went into the service of the P. and O. Company. Later he acted for a time as dispensary physician at the Infirmary, obtained the D.P.H. in 1896, and that of F.R.F.P.S. Glasg. in 1898. He was appointed professor of forensic medicine and lecturer in hygiene at St. Mungo's College, Glasgow, and was for a period dean of the medical faculty, and pathologist and lecturer on hygiene at the Glasgow Royal Infirmary. His services as examiner were frequently in demand, for he acted in this capacity both in medical jurisprudence and in hygiene for the Scottish Conjoint Board, and in medical jurisprudence for the Royal Faculties of Glasgow. Some 25 years ago Galt left Glasgow and going to Brighton was appointed pathologist to the Stephen Ralli memorial laboratory at the Royal Sussex County Hospital. He took an

active part in the Brighton and Sussex scheme for the prevention of venereal disease, while his services as an expert witness were often in demand. During the war he was attached with the rank of captain, R.A.M.C., to the 2nd Eastern General Hospital, Brighton.

Galt, who was for a period Crown medico-legal examiner for Glasgow and Lanarkshire, had made during his career as a jurispudent an enormous number of post-mortem examinations and given medical evidence in several sensational trials. He retired from practice two years ago.

RICHARD JOHN MORRIS, C.B.E., M.D. Durh., M.R.C.P. Lond.

THE death occurred at Harrogate on Jan. 23rd of Dr. R. J. Morris, after a long and painful illness bravely borne.

Richard John Morris was born at Rosscarbery, Co. Cork, and received his education at the Diocesan School, Rosscarbery, and Queen's College, Cork. After graduating as L.S.A. in 1884 he settled in practice at Lancaster. Here he joined the Volunteer Battalion of the King's Own Royal Lancaster Regiment from which he retired in 1910 with the rank of Major. An excellent rifle shot, he captained the Irish International Twenty Team at Bisley from 1896-1900. After his marriage in 1895 he entered St. Bartholomew's Hospital and qualified as M.R.C.S., L.R.C.P. in 1900, subsequently taking the M.D. Durh. and M.R.C.P. Lond. He studied at Bordeaux under Prof. Bergonié, and then settled in Harrogate as a spa physician. In 1915 he was appointed to the Northern Command Depot at Ripon with the rank of Lieut.-Colonel. For his services he was made Commander of the Order of the British Empire. At the end of the war he had a severe illness from which he never entirely recovered; but in spite of ill-health he continued with his practice, and during this period was successively chairman of the Harrogate division of the British Medical Association and president of the Harrogate Medical Society.

Dr. Morris was a good sportsman and a good friend; he will be much missed by those who knew him best. He leaves a widow for whom sympathy will be felt. There are no children.

LLOYD MIDDLETON BOWEN-JONES, M.R.C.S. Eng., D.P.H.

THE death occurred on Feb. 2nd of Dr. Lloyd Bowen-Jones, of Carmarthen, who was well known in his district, having been medical officer of health for the borough for 33 years and of the Carmarthen rural district for a still longer period. The son of the Rev. Richard Bowen-Jones, J.P., he received his medical education at Guy's Hospital, where he was for a time resident obstetric physician. He acted as house physician at the Seamen's Hospital before returning to his native Wales to practise. There he held other local appointments in addition to those mentioned, and was in particular a pioneer in the fight against tuberculosis. He was personally responsible for large subscriptions to the erection of the West Wales Sanatorium, and when the institution was taken over by the Welsh National Memorial Association he became chairman of the house committee, while a ward opened at the sanatorium was named after him. Dr. Bowen-Jones was 83 years of age at the time of his death.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

School Home Work and Children's Health

THE House of Commons on Feb. 12th agreed without a division to a motion by Mr. Radford that it is undesirable for school-children to have their evenings occupied with home work to the exclusion of rest and recreation, and that, whenever practicable, preparation on the school premises should be substituted for home work. Among many striking examples of abuse of home work he cited the testimony of a vicar whose choir boys attended a grammar school where so much home work was given that the boys had to work on Sundays in order to be ready for Monday. It was, he thought, extraordinary that such a state of affairs should be tolerated for children of tender years by a nation so solicitous of their welfare when they were a little older.—Sir Ernest Graham-Little, in supporting the motion, said it was a reproach to a teacher if the child was required to do much home work; teachers were, however, handicapped by the size of their classes.—Mr. G. A. Morrison was more anxious for girls than boys in view of Sir Henry Hadow's observation that if one gave a girl too much to do she broke down but if one gave a boy too much to do he did not do it.—Mr. Potts, while agreeing that home work might be useful, thought there was a reasonable limit beyond which if they overworked children's brains they were doing more harm than good.—Mr. Lees-Smith said the reason for overpressure, the curse of secondary education, was the school certificate examination, schools being judged by the number of their matriculation successes.—Mr. Oliver Stanley, in a sympathetic reply, said the Board of Education was actually in the middle of a comprehensive inquiry into the whole question of school home work. The Government were determined to see that whatever was wrong was remedied.

Extension of Milk Subsidy Scheme

In the House of Commons on Feb. 17th the financial resolution in connexion with the Milk (Extension of Temporary Provisions) Bill was considered in Committee.

Mr. RAMSBOTHAM, Parliamentary Secretary to the Ministry of Agriculture, in moving the resolution recalled the circumstances of crisis in which the original Act was passed in 1934. He said that the milk marketing scheme then inaugurated was particularly welcome to the Board of Education because that Department had for some time been contemplating an intensive drive in the direction of more extended physical education and training for children, which would also necessitate greater attention to the health of the children so trained. It was obvious that they could not neglect the provision of better facilities for diet and nourishment for those to be trained. For that reason, the action taken under the Milk Act of 1934 to provide cheap milk for children was one of the best actions ever taken by any Government. The scheme was still in its experimental stage and there was need in many directions for further investigation. Even if it were possible at the moment to embark on a long-term policy it would still be advisable to operate the milk-in-schools scheme on an experimental basis to remove various difficulties before placing it on the permanent basis on which he trusted it would one day be placed. By the spring of 1935 the number of children in public elementary schools taking milk had increased to about 2,500,000. If they added the children in grant-aided schools the number to-day was in the neighbourhood of 2,750,000 and the consumption was just on 23,000,000 gallons. There were still, however, about 2,800,000 scholars who were not

drinking milk in schools, that was more than 60 per cent. of the school population.

The Government to-day were faced with three alternatives. First, that the provisions of the Act of 1934 should be allowed to lapse. That would be deplorable. Secondly, they might retain the milk-in-schools scheme and terminate the assistance given to manufacturing milk, devoting the amount of that assistance to providing further cheap milk for children. That would severely shake the price structure of the industry, by leaving an immense gallonage on the manufacturing market. The Government were therefore left with the third alternative, which he recommended to the Committee. It was that they should continue their action along the lines of the 1934 Milk Act and extend those provisions in accordance with this financial resolution.

CRITICISM OF GOVERNMENT POLICY

Mr. T. JOHNSTON said he could not understand, when Mr. Ramsbotham said there must be a further investigation, what there was to investigate. The facts were beyond dispute. Men like Sir John Orr had committed themselves to the statements that we could increase the height of our school-children by 3 in. and increase their weight by 4 to 6 lb., and the Leighton-McKinlay experiment in Lanarkshire, though covering only a period of four months, seemed to justify to the full the statements made by Sir John Orr and the other experts who had made this subject their own. We were facing now, in winter time, 27 per cent. of an alleged milk surplus, but the Government did not know what to do with it. They were providing considerable sums of money to convey the surplus into dried milk, condensed milk, and other uses. It was a remarkable fact that in a land where at least 10 per cent. of our people lived below the British Medical Association's standard of nutrition, we raised money to destroy an absolutely essential food.

There was a need for supplying liquid milk to the consumers of this country.

As a result of prolonged study nutrition experts had discovered, particularly in the Newcastle area, that 47 per cent. of the children of the poor were below standard weight, that 23 per cent. were anemic, and 36 per cent. were unhealthy and unfit. The last report, for 1932, showed that 52 per cent. of the recruits applying for admission to the British Army failed on physical grounds, and that of the 48 per cent. who got through 36.9 per cent. were subsequently rejected on medical grounds. A League of Nations committee of experts reported on the Physiological Bases of Nutrition, and said that there should be at least one litre of milk a day for expectant and nursing mothers, as well as an abundant supply for infant children of all ages and adolescents. The practice of providing milk, either free or at a reduced price, was highly recommended. The Orr-Lloyd investigations showed that 10 per cent. of our people were not spending 4s. per head on food, yet the British Medical Association's figure was 5s. 10½d. per week as a minimum. There were at least another 20 per cent. just on the borderline of the Association's minimum standard.

The hospitals, infirmaries, clinics, and poor-law institutions were in a terrible plight, and the Government were busily engaged in organising a policy of increasing the cost of milk to voluntary hospitals, infirmaries, and clinics. At the Royal Hospital for Sick Children in Glasgow the Government's milk policy raised the cost of milk to these poor sick children by £500 a year. The cost to the Royal Infirmary had gone up by £1500. The jump in the figure for the hospitals of the Lanarkshire county council was £800, and for the Glasgow town council hospitals, £12,300. There was something inherently wrong in that. He recognised that it was not a practicable proposal at the moment to ask that milk

should be supplied free to the hospitals and institutions, but surely the Minister could make it imperative that the price to be charged for milk should be the pre-Milk Order price, that at which they were getting milk before the Marketing Boards started to raise prices. Then the hospitals and clinics would use more milk.

After further debate,

REPLY BY THE MINISTER OF AGRICULTURE

Mr. ELLIOT said that 2,750,000 children were getting milk to-day who would not have been getting milk if these proposals had been defeated two years ago. Not only that, but they were getting milk at half the price at which they were getting it then, and another great army besides. What was more, the cheapening of the milk to the local authorities had meant the doubling of those who were getting milk entirely free. They had to do two things—to maintain the milk industry and the production of milk and also to secure so far as they could the health and upbuilding of the future generation. No greater injury could be done to either than to try to fuse the two. If they advanced the cause of health in the schools on the ground of merely finding a receptacle for the surplus of milk, or anything else, they would defeat their own objects. He welcomed the criticism which had been made about the defects in the milk-in-schools scheme and he was asking the Committee for a further extension of time in order to investigate them. This period of test—not of experiment—of administrative experience would be most valuable when they came, as they would within a few months, to the framing of the long-term policy in this section of agriculture. Refuting the suggestion that milk was being destroyed for food purposes the right hon. gentleman said that not a penny of Government money had been spent on any milk that was going to any other process than the processing of milk for food. As to the improvement of the quality of the milk-supply steps had been taken by the Government and the Milk Marketing Board to improve the quality by making a levy on all producers and giving a bonus of a penny a gallon on all milk which came up to the standard of Grade A; and in a relatively short space of time they had brought 27 per cent. or more of the milk up to Grade A standard. That was a far greater improvement in the quality and the cleaning up of the milk than had been obtained in any comparable time by any other administrative measure. When the statement was made that the Government should here and now adopt some ad hoc method for children, and more particularly for adults, in ensuring the consumption of milk, he thought that the Committee would be well advised to consider well before embarking on that step. He had heard suggestions that cards should be sold by the Ministry of Labour to the unemployed whereby they could buy more milk. That seemed to him to be coming terribly close to the issue of ration cards. There was a grave danger of segregation of the classes in some of these proposals.

Mr. JOHNSTON: Will the right hon. gentleman say a word or two about the position of the hospitals and infirmaries and the increase that they have been compelled to pay

Mr. ELLIOT said that while he had the utmost sympathy with the desire of those institutions to get their milk-supplies at a lower rate, he was afraid that he could not concede the main point that if they got them at a lower rate they would purchase more. As far as the hospitals were concerned it was exactly that case that he had tried to make again and again and he had been defeated by the obvious answer that the hospitals would buy as much as was necessary for the needs of their patients, but that no amount of cheap milk would alter the figures. Certainly if any scheme could be worked out he would support it forthwith. If not, then he was afraid they could not solve the question under this method; they must wait for the long-term measure.

The resolution was carried by 213 votes to 140.

Committee on Child Adoption

In answer to a question put to him in the House of Commons on Feb. 13th, whether he had considered the representations made to him in regard to the alleged existence of abuse in connexion with the adoption of children, Sir JOHN SIMON said he had appointed a committee to inquire into the matter consisting of Miss Florence Horsbrugh, M.P. (chairman), Mr. Benjamin Edward Astbury, Mr. John Henry Harris, Mr. J. J. Mallon, LL.D., J.P., Mr. Brian Manning, F.C.A., J.P., Mrs. Montagu Norman, and Mr. Geoffrey W. Russell, with Mr. J. A. R. Pimlott of the Home Office (secretary). The committee would inquire into the methods pursued by adoption societies or other agencies engaged in arranging for the adoption of children and report whether any, and, if so, what measures should be taken in the public interest to supervise or control their activities.

HOUSE OF COMMONS

WEDNESDAY, FEB. 12TH

British Red Cross Units in Abyssinia

Mr. MANDER asked the Secretary of State for Foreign Affairs if he had information as to how many British subjects were serving Red Cross units in Abyssinia; what attacks had been made on these units by the Italian air force; and whether any undertaking had been asked for or obtained from the Italian Government that no further attacks would be made on Red Cross units.—Mr. EDEN replied: According to such information as is available, I understand that 19 British subjects are serving in the British Red Cross hospital and other ambulance units, foreign and national, in Ethiopia. This figure does not include native dressers, transport drivers, and other junior non-European personnel recruited in Kenya or British Somaliland, for service with these units. As regards the second part of the question, I would refer the hon. Member to the reply I gave on Feb. 10th. As regards the last part, the Italian Government have been officially notified, through H.M. Embassy in Rome, of the sphere of action of the British Red Cross unit now operating with the Ethiopian forces on the northern front.

Interpretation of Poisons Rules

Sir ERNEST GRAHAM-LITTLE asked the Home Secretary whether he would, in view of the variety of interpretations given to it, state what was the precise meaning to be attached to the word manufacture as used in Rule 29 of the Poisons Board Rules issued in December, 1935; and whether that word covered the processes of compounding and dispensing medicines containing poisons and used for the treatment of internal human ailments.—Mr. GEOFFREY LLOYD, Under-Secretary, Home Office, replied: Rule 29 of the Poisons Rules has been made under Section 23 (1) (i) of the Pharmacy and Poisons Act, 1933, which gives power for rules to be made "for requiring persons in control of the manufacture of pharmaceutical preparations containing poisons to be registered pharmacists or persons possessing the prescribed qualifications in chemistry." It seems to me clear that the word "manufacture," both in the Act and in the Rule, denotes only the operations carried on in factories by manufacturers, and does not cover such operations as the compounding and dispensing of their own medicines by medical practitioners.

THURSDAY, FEB. 13TH

Writing of Medical Prescriptions

Lieut.-Colonel MOORE asked the Home Secretary whether, in view of the recent disclosures at coroners' proceedings that doctors wrote prescriptions so illegibly that in many cases the address and signature were indecipherable and of the serious developments to which such practices were giving rise, especially in the issue of drugs, he would consider taking action to ensure that prescriptions should not be dispensed unless easily legible.—Sir JOHN SIMON replied: I have no information that would lead me to suppose that the practice referred to is prevalent or has been productive of any harm to the

public. There are, as the hon. Member will be aware, various legal requirements in regard to the dispensing of poisons and dangerous drugs which seem to provide such safeguards as may be necessary.

Amidopyrin Scheduled as a Poison

Mr. HALL-CARNE asked the Home Secretary whether his attention had been called to the increase of deaths by poisoning due to pyramidon; and whether steps were to be taken to ensure that this would be classed as a poison at the earliest opportunity.—Sir JOHN SIMON replied: Yes, Sir. Under the new Poisons List and Rules which are to come into operation on May 1st next, this drug (which is more correctly described as amidopyrin) will be scheduled as a poison and its sale to the public will be unlawful except on medical prescription.

Tuberculosis (Attested Herds) Scheme

Mr. WILFRID ROBERTS asked the Minister of Agriculture how many herds in England and Wales have now been attested under the Tuberculosis (Attested Herds) Scheme; how many of these herds were previously licensed as Grade A (T.T.) or certified herds; and what the total costs had been to date in administration and in the payment of the premium of 1d. per gallon.—Mr. ELLIOT replied: Sixty-five herds have been attested in England and Wales under the Tuberculosis (Attested Herds) Scheme. Of these, 22 are herds licensed to produce Grade A (T.T.) and Certified milk. The total cost of administering the scheme to date, including £1485 in respect of the expenses incurred in a course of training of the Ministry's inspectors in the uniform application of the tuberculin test and £1430 in experimental investigations for improving and perfecting the technique and material used in the application of the test, is £9600. A further sum of £715 has been paid in respect of the premium of 1d. a gallon for milk sold from attested herds through the Milk Marketing Scheme.

Anæsthetics in Municipal and Voluntary Hospitals

Mr. EDWARD DUNN asked the Minister of Health if there were any statistics available which showed the difference in the mortality-rate where gas-and-oxygen was used as the anæsthetic as against the use of chloroform and ether in municipal and voluntary hospitals.—Sir KINGSLEY WOOD replied: I am not aware that any statistics of this character are available. Certain information in regard to deaths during or connected with the administration of anæsthetics of all kinds is contained in the Text Volume of the Registrar-General's Statistical Review for the year 1933.

Ambulance Service at Enfield

Mr. BULL asked the Minister of Health under what circumstances the ambulances of local authorities were permitted to be used for the conveyance of sick persons not suffering from any infectious disease, as well as for cases of acute surgical and medical emergency; whether his attention had been called to the absence of such permission in the case of the Enfield ambulance service; and whether this matter could be reviewed.—Sir KINGSLEY WOOD replied: A local authority which has provided an ambulance for the conveyance of persons suffering from infectious disease has power to use it for the conveyance of other sick persons with suitable precautions. In Enfield the power of providing ambulances for infectious disease vests in the joint hospital board and not in the urban district council, and I understand that the council are actively considering means of getting over this difficulty. The Departmental Committee on the Consolidation of the Law relating to Local Government and Public Health have considered the question of the provision of ambulances by local authorities and have recommended a simplification of the law.

Vaccine Lymph from Rabbits

Mr. LEACH asked the Minister of Health whether rabbits were still used in the Government lymph establishment in connexion with the production of calf lymph, notwithstanding the opinion of certain vaccination experts that the use of rabbits was probably the cause of the cases of post-vaccinal encephalitis which had followed the use of such lymph in recent years.—Sir KINGSLEY WOOD replied: Yes, Sir. I am advised that there is no valid evidence to suggest that the use of rabbits in the preparation of

lymph has any influence on the occurrence of post-vaccinal encephalitis.

Mr. GROVES asked the Minister of Health whether rabbits were still used in the Government lymph establishment in connexion with the production of the supplies of calf lymph issued to public vaccinators; and what measures were adopted to secure that the rabbits so used were not suffering from spontaneous encephalitis.—Sir KINGSLEY WOOD replied: The answer to the first part of the question is in the affirmative. As regards the second part, the rabbits are born and reared on the premises and are used at the age of three to four months. There is, therefore, ample opportunity for observing their condition. Further, as I am advised, there is no affinity between the encephalitis of rabbits and post-vaccinal encephalitis.

Clothing and Footwear for Necessitous Children

Mr. ELLIS SMITH asked the President of the Board of Education if it was the intention of the Government to institute legislation which would enable education authorities to provide clothing and footwear for necessitous school-children.—Mr. OLIVER STANLEY replied: The whole question of the provision of clothing and footwear for necessitous children was raised by a deputation from the Association of Education Committees which I received on Jan. 16th, and I am at present considering it.

MONDAY, FEB. 17TH

Disabled Soldiers and Hospital Allowances

Mr. DAVID DAVIES asked the Minister of Pensions (1) the amount of allowances at present paid to disabled soldiers attending hospitals for treatment due to disabilities caused by the Great War, distinguishing the cases of men who were forced to leave their employment and the cases of men who were unemployed, and (2) the number of ex-Service men who attended hospitals under the Ministry during 1936 for treatment, who had not received any treatment allowances, and whose wives and dependants, in consequence of the failure of the Ministry to provide allowances, had been compelled to seek poor-law relief.—Mr. R. S. HUDSON replied: In the case of men who are normally in employment before admission and who suffer loss of wages or profits on account of admission to hospital, allowances are payable in accordance with the terms of the Royal Warrant. In the case of men who were unemployed before admission but were in receipt of either unemployment benefit or allowances from the Unemployment Assistance Board before admission to hospital, supplementary grants are payable in accordance with the announcement which I made in the House on Oct. 22nd last, which substantially meet the loss of income suffered by their families. The object of this, as I stated at the time, was to obviate the necessity of their families having to have recourse to the poor-law solely on account of the man's admission to a Ministry Hospital. Although I have no statistics which would enable me to answer the hon. member's second question, I am satisfied that in general my object has been achieved.

Milk Production and Consumption

Sir FRANCIS ACLAND asked the Minister of Agriculture the total milk production for England and Wales for each of the last four calendar years; and the estimated amounts consumed as liquid milk and used in factories for milk products.

Mr. THOMAS WILLIAMS asked the Minister of Agriculture the quantities of milk sold for liquid consumption by the Milk Marketing Board and producer retailers; and the quantities sold for manufacturing purposes during the years 1934 and 1935.—Mr. ELLIOT replied: The estimated total production of milk in England and Wales in the four years 1931/32-1934/35 is as follows:—

Years (June to May)	Million gallons
1931/32	1·303
1932/33	1·349
1933/34	1·379
1934/35	1·399

The foregoing figures represent the total amount of liquid milk estimated to have been available for all purposes

other than for feeding to stock, and are based on the information obtained through the voluntary census of 1930/31, assuming that the average lactation yield has not changed since that date. The information at my disposal is not sufficient to enable me to say how much of the total production was consumed as liquid milk and how much was used in factories for milk products. The following particulars of milk sold for liquid consumption and for manufacture by the Milk Marketing Board have been supplied by the Board.

	Year ended.	
	Sept. 30th, 1934.	Sept. 30th, 1935.
Sold for liquid consumption—	Gals.	Gals.
(a) Under wholesale contracts ..	523,813,326	554,174,376
(b) By producer-retailers ..	109,970,885	104,932,128
—	633,784,211	659,106,504
Sold for manufacture	192,623,561	301,829,328

Milk Prices and Public Demand

Mr. ACLAND asked the Minister of Agriculture whether any experiments analogous to the Bishop Auckland potato experiment had been made to ascertain the effect of differential milk prices on the public demand for milk; if so, what were the results; and, if not, whether any such experiments were in contemplation.—Mr. ELLIOT replied: No experiment to ascertain the effect of differential prices on the public demand for milk has, so far as I am aware, been made on the lines of that conducted by the Potato Marketing Board at Bishop Auckland. The Milk Marketing Board for England and Wales prepared a scheme for the supply of milk at special prices to unemployed in the Merthyr Tydfil district, one object of which was to ascertain the effect of reduced prices on demand, but it was not found possible to introduce the scheme. Other schemes are still under consideration, but I cannot at present say whether it will be possible to proceed with them.

Supply of Milk in Schools

Miss RATHBONE asked the Minister of Agriculture what had been the amount of the Exchequer grant actually paid during the last 12 months, or other ascertainable period, towards the supply of milk in schools and, secondly, towards the cost of milk supplied to manufacturers for milk products; and what had been the average price per gallon received by the farmers in both cases.—Mr. ELLIOT replied: During the first 12 months (Oct. 1st, 1934, to Sept. 30th, 1935) of the operation of the Milk-in-Schools Scheme in England and Wales, 22½ million gallons of milk were consumed in respect of which the Milk Marketing Board received £401,000 in grants from the Exchequer, an average rate of 4'23d. per gallon. During the same 12 months (Oct. 1st, 1934, to Sept. 30th, 1935) (for which information is not yet complete) 200 million gallons of milk were processed in England and Wales in respect of which the Milk Marketing Board received £1,061,000 by way of Exchequer advances, an average rate of 1'27d. per gallon. Individual producers actually received in respect of both supplies the Pool Price which has averaged throughout the 12 months in question 11'99d. per gallon.

Mr. WILFRID ROBERTS asked the Minister of Agriculture the average number of children that had obtained milk daily under the Milk-in-School Scheme in each quarter since the passing of the Milk Act, 1934, and what the cost had been to the Exchequer.—Mr. ELLIOT replied: Precise figures showing the average number of children that have obtained milk daily under the Milk-in-Schools Scheme in each quarter since the passing of the Milk Act, 1934, are not available, but at the end of March, 1935, the number of children receiving milk under the scheme, free or for payment, in grant-earning schools in England and Wales was about 2½ million. At the beginning of October, 1935, the corresponding figure was about 2½ million. Exchequer grants amounting to £447,495 have so far been paid to the Milk Marketing Board for England and Wales

in respect of milk supplied during the period Oct. 1st, 1934, to Oct. 31st, 1935. For similar information relating to Scotland, I would refer my hon. friend to my right. hon. friend the Secretary of State for Scotland.

Mr. THOMAS WILLIAMS asked the President of the Board of Education if he would give the figures for the latest dates available of the number of school-children who received a free supply of milk and the number who received milk at schools at the reduced price, and the total annual consumption of each category.—Mr. OLIVER STANLEY replied: The number of school-children receiving free milk in all types of grant-earning schools in England and Wales was about 300,000 on Oct. 1st, 1935, the latest date for which figures are available. The number who received milk at school at that date at the reduced price under the Milk-in-Schools Scheme was about 2½ millions. The annual consumption by the children who pay for milk is about 22,500,000 gallons. The annual consumption by the children who receive free milk cannot be accurately estimated, as these children receive varying amounts of milk, but it is probably about 4 million gallons.

Miss RATHBONE asked the President of the Board of Education what would be the cost of supplying a free ration of one-third of a pint of milk every school day to every child in elementary schools, and upon what number of children and price of milk was the estimate based; and what would be the additional cost if the provision were extended to week days when schools did not meet.—Mr. OLIVER STANLEY replied: There are about 5,300,000 children attending public elementary schools in England and Wales. To supply this number with one-third of a pint of milk daily for 200 school days about 44 million gallons of milk would be required. Including week-days when the schools do not meet about 69 million gallons would be required. I am not in a position to give an estimate of the cost to public funds which would be involved if this quantity of milk were supplied free, as the price per gallon could only be determined after negotiations with the milk industry.

The Attested Herds Scheme

Mr. ACLAND asked the Minister of Agriculture whether he could give, to the most recent convenient date, figures showing the number of producers of milk entitled to receive the bonus for pure milk provided by the Milk Act of 1934; what was the output of such producers; and what improvement the figures showed over the corresponding figures at any earlier date.—Mr. ELLIOT replied: The number of producers of milk from herds certified by the Ministry under the Attested Herds Scheme to date is 59, who own a total of 65 herds, comprising 2558 animals which have been attested at various dates since Feb. 1st, 1935. Twenty-two of the herds are licensed to produce Certified or Grade A (T.T.) milk, and in cases in which the owners have claimed exemption in respect of such milk from the Milk Marketing Scheme, they are not entitled to receive the bonus under the Attested Herds Scheme. The only figures indicating output are contained in the claims for the 1d. per gallon bonus payable in respect of milk sold through the Marketing Scheme. Claims have been received in respect of 40 herds only, covering an average of about five months each, and a total production of 237,076 gallons. There are no corresponding figures in respect of any previous period.

Elimination of Bovine Tuberculosis

Mr. ACLAND asked the Minister of Agriculture what sums the Government had spent since 1934 on experiments to discover means of eliminating bovine tuberculosis; and whether any results had been achieved.—Mr. ELLIOT replied: Research on bovine tuberculosis has been in progress for some years at the Institute of Animal Pathology, Cambridge, and, to some extent, at the Ministry's Veterinary Laboratory, and the National Institute for Research in Dairying at Reading. It is not possible to give a precise figure of the sums expended, which form part of the general expenditure of the institutions named. Since 1934, however, in consultation with the Agricultural Research Council, special grants have been made to extend the work at Cambridge, amounting to £375 in the year ended March 31st, 1935, and £5320 in the year ending March 31st next. The subjects of the investigation are

the use of BCG vaccine and of tuberculin and the work is still in progress.

Scarlet Fever and Destruction of School Books

Mr. ANDERSON asked the President of the Board of Education if his attention had been called to the burning of school books in the Pinxton district of North Derbyshire owing to an epidemic of scarlet fever; and if the method stated was universal; and, if so, what was the cost during the past 12 months in renewal of books and the department or authority responsible for the cost.—Mr. OLIVER STANLEY replied: I have no information regarding the burning of school books in the Pinxton district, but I am making inquiries. I understand that it is not the universal practice to destroy school books after an epidemic, but the question in a particular case is one to be decided by the local education authority on the advice of the Medical Officer of Health. I have no information as to the cost involved in the renewal of books destroyed in this way during the past 12 months, but any such expenditure by a local education authority would receive grant from the Board.

TUESDAY, FEB. 18TH

Stone-dusting Regulations in Mines

Mr. DAVID DAVIES asked the Secretary for Mines the number of samples of coal dust taken by the inspector of mines, under the stone-dusting regulations, in 1935; giving the number that did not comply with the requirements provided in the regulations and stating the volatile content of the coal seams in the cases where the samples

taken were not in accordance with the stone-dusting regulations.—Captain CROOKSHANK replied: The number of mine road dust samples taken by inspectors of mines in 1935, under the regulations relating to precautions against coal dust, was about 6500, of which 520 did not comply with the requirements of the regulations. I regret that the information asked for in the last part of the question is not available.

Research on Diseases of Animals

Sir ARNOLD WILSON asked the Lord President of the Council whether, in view of the fact that apart from members of the veterinary profession serving on the committees dealing with diseases of animals there was no representative of the profession on the Agricultural Research Council, he would consider strengthening the Agricultural Research Council by the addition of representatives of the veterinary profession.—Mr. RAMSAY MACDONALD replied: It is not considered desirable that professions as such should be represented on the Agricultural Research Council. The Committee of the Privy Council for the Organisation and Development of Agricultural Research decided, however, at a recent meeting that the representation on the Agricultural Research Council of the sciences underlying the study of animal health should be strengthened. They therefore approved the appointment of Mr. John Smith, O.B.E., M.R.C.V.S., D.V.H., formerly Director of Animal Health in Northern Rhodesia, and since 1933 a member of the Colonial Advisory Council of Agriculture and Animal Health, as a member of the Agricultural Research Council.

MEDICAL NEWS

University of Cambridge

At recent examinations the following candidates were successful:—

D.M.R.E.

*R. E. Alderson, Sylvia D. Bray, G. Q. Chance, W. J. Craig, I. T. Dickson, Isaac Eban, N. G. Gadekar, V. R. Ginde, Mary C. Leishman, R. B. Mehta, A. N. Nanda, L. D. Pringle, A. M. Rackow, A. I. Silverman, A. C. Sinclair, Edith H. Smith, Florence L. Telfer, *William Tennent, and D. A. Wilson.

* Distinction.

Royal College of Surgeons of England

A meeting of the council of the College was held on Feb. 13th with Sir Cuthbert Wallace, the president, in the chair. It was decided that the Hunterian dinner which could not be held this year should take place on Feb. 15th, 1937. The Hallett prize for December, 1935, was presented to Robert Sutherland Lawson of the University of Melbourne.

The offer by the *British Journal of Surgery* of 1000 guineas to be expended in research work in surgery was accepted, and the council gave permission for the erection in the College of a tablet to record the services of Lord Moynihan to surgery and the journal. It was reported that Prof. Einar Key, of Stockholm, had accepted the honorary fellowship of the College, and that he would attend the meeting of the council on June 11th to be admitted. Mr. R. E. Kelly was reappointed as the representative of the College on the court of the University of Liverpool for three years, and Sir Holburt Waring was appointed representative of the College at the congress of the Universities of the Empire to be held in Cambridge in July.

The council passed a vote of condolence on the death of Sir Charles Ballance, a past vice-president of the College.

The posts of resident surgical officer and first house surgeon at the Croydon General Hospital were approved for recognition for the six months' surgical practice required of candidates for the final fellowship examination.

Diplomas of fellowship were granted to Theodor Anton Green and Josephus Corbus Luke, and diplomas of membership to S. Alankaram and to the candidates given in our issue of Feb. 8th (p. 339). Diplomas in public health, medical radiology, and anaesthetics were granted jointly with the Royal College of Physicians to the candidates mentioned in the same issue (p. 340).

University of Wales

Three research scholarships in the University of Wales will be awarded in the session 1936-37. Particulars will be found in our advertisement columns.

University of Sheffield

Prof. J. H. Dible has been appointed external examiner in pathology and bacteriology, Prof. E. J. Wayne representative of the university on the National Council for Domestic Studies, and Prof. G. L. Roberts on the Dental Education Advisory Committee.

British College of Obstetricians and Gynaecologists

At a recent meeting of the council the following were promoted to the fellowship of the college:—

Jack Roland Stanley Grose Beard (Adelaide), Alexander Ernest Chisholm (Dundee), John Francis Cunningham (Dublin), Constance Elizabeth D'Arcy (Sydney), Ernest Chalmers Fahmy (Edinburgh), Margaret Fairlie (Dundee), John Gardner (Glasgow), Robert Lance Impcy (Cape Town), Robert Aim Lennie (Glasgow), Hilda Nora Lloyd (Birmingham), Rupert Eric Magarey (Adelaide), John Chassar Moir (London), and William Foster Rawson (Bradford).

Royal College of Surgeons in Ireland

The Charter Day dinner was held last Saturday in the hall of the college, with Mr. Seton Pringle, the president, in the chair. There was an attendance of nearly 120, the guests including the Lord Mayor of Dublin (Mr. Alfred Byrne), the American Minister to the Irish Free State (the Honourable Alvin Owsley), and the Vice-Chancellor of Queen's University, Belfast (Mr. F. W. Ogilvie). In his speech the president spoke of the danger of too many students seeking admission to the medical profession with the resulting possibility of overcrowding. He suggested that the medical schools should raise the standard of general education required for entrance, and he quoted examples of the low degree of education exhibited by some candidates. Prof. T. G. Moorhead, who replied for the guests, spoke of the union recently effected between the Irish Medical Association and the Irish Free State branches of the British Medical Association, and asked for support of the union from all members of the profession. He also spoke of the prospects of establishing a Medical Research Council, to be financed from sweepstake funds. He said that the profession would not bring into being any council that had not full control over the moneys that were granted for medical research, nor any council with merely advisory functions.

Dr. C. P. Martin, professor of anatomy at Trinity College, Dublin, has been appointed to the chair of anatomy at McGill University, Montreal.

Dr. Douglas Lee, late Sharpey scholar in the physiology department at University College, London, has been appointed to the chair of physiology at the Singapore Medical College.

Royal Sanitary Institute

At a meeting on housing to be held at this institute (90, Buckingham Palace-road, London, S.W.), on Tuesday, March 10th, at 5.30 P.M., Sir Raymond Unwin will open a discussion on planned distribution as a means of preventing crowding. Lord Balfour of Burleigh, the president, will take the chair.

Bilton Pollard Fellowship

An award of this fellowship, which has an annual value of £650, will shortly be made to a man student who has held a resident appointment at University College Hospital where the fellowship is tenable. Candidates must be members of the Royal College of Physicians of London or fellows of the Royal College of Surgeons of England, and must intend to practise in medicine or surgery. Full particulars may be had from the secretary of the hospital, Gower-street, London, W.C.1, and applications for the fellowship must be made before March 2nd.

London Inter-Collegiate Scholarships Board

This board announces that an examination for twelve medical scholarships and exhibitions, of an aggregate total value of £1418, will begin on May 11th. They are tenable at University College and University College Hospital medical school, King's College and King's College Hospital medical school, the London (Royal Free Hospital) School of Medicine for Women, the London Hospital medical college, and St. George's Hospital medical school. Full particulars and entry forms may be obtained from the secretary of the board at King's College Hospital medical school, Denmark Hill, S.E. 5.

Course on Mental Deficiency

A course of lectures on mental deficiency and allied conditions has been arranged for medical practitioners by the extension and tutorial classes council of the University of London in co-operation with the Central Association for Mental Welfare. The course, which will be supplemented by clinical instruction, is divided into two parts (mental deficiency, April 20th to 25th; retarded and difficult children, April 27th to May 2nd), and these may be taken separately. Applications should reach Miss Evelyn Fox, University Extension Department, University of London, South Kensington, S.W.7, by March 30th.

The Food Education Society

Three lectures will be given by Maj.-General Sir Robert McCarrison at the London School of Hygiene and Tropical Medicine, Keppel-street, W.C., on consecutive Thursdays at 5 P.M. on nutrition and health (March 12th); food in relation to the structure and functions of the body (March 19th); and nutrition and national health (March 26th).

A lecture on winter salads will be given by Mrs. Jenny Fliess at the Soho School of Cookery, 20, Soho-square, London, on Thursday, March 5th, at 3.30 P.M. Tickets may be obtained from the Food Education Society, 29, Gordon-square, W.C.1.

Tuberculosis Conference

The tenth conference of the International Union against Tuberculosis will meet in Lisbon from Sept. 7th to 10th under the chairmanship of Prof. Lopo de Carvalho, who will open the discussion on radiological aspects of the hilum of the lung and their interpretation. Dr. Olaf Scheel (Norway) is speaking on primary tuberculous infection in the adolescent and the adult, and Dr. C. J. Hatfield (United States) and Dr. D. A. Powell (Great Britain) on the open case of tuberculosis in relation to family and domestic associates. Other speakers will include Dr. W. T. Munro and Dr. L. S. T. Burrell. Further information may be had from the National Association for the Prevention of Tuberculosis, Tavistock House North, Tavistock-square, London, W.C.1.

THE untimely death at the age of 37 of Dr. Erroll Williams, of Southport, aroused general sympathy in the neighbourhood, for he had only been married a short time and had made a good impression on the public and his colleagues during his residence in the town. He served in the Royal Flying Corps during the war and gained the Distinguished Flying Cross.

The Minister of Pensions has appointed Dr. Michael Abdy Collins, O.B.E., to the post of Mental Inspector to the Ministry.

Taunton and Somerset Hospital

An appeal for £35,000 is being made to build additional wards and modernise this hospital.

New Casual Wards at Enfield House

The Middlesex county council have provisionally agreed to erect new casual wards at Enfield House to take the place of those in use at Edmonton House and also to build at Chase Farm, Enfield, two additional blocks for able-bodied inmates from Enfield House and Edmonton House.

Ramsbottom Cottage Hospital

Lieut.-Colonel Porritt and his wife have offered to pay the building costs of extensions at this hospital which include a new children's ward and a new operating theatre.

Bovey Tracey Hospital

A new children's ward was opened at this hospital on Feb. 5th to commemorate King George's jubilee.

Salford Royal Hospital

The out-patient department at this hospital, which was opened in 1911, is to be completely transformed as it is inadequate for present-day needs. The massage department, at present housed in a hut in the hospital yard, is to have a new building and the provision of a nurses' recreation room is under consideration.

Maternity and Child Welfare Conference

A national conference on maternity and child welfare will be held at the Picton Hall, Liverpool, on July 1st, 2nd, and 3rd under the presidency of Mr. Geoffrey Shakespeare, parliamentary secretary to the Ministry of Health. The subjects for discussion will include maternal welfare and the public; antenatal nutrition; the education of parents through day nurseries and nursery schools; parents and substitute parents; the importance of co-operation between maternity and child welfare services and the specialist health services; and rest and convalescence as factors in maternal welfare. The conference is being organised by the National Council for Maternity and Child Welfare and by the National Association for the Prevention of Infant Mortality. The maternity and child welfare group of the Society of Medical Officers of Health is also co-operating in the conference, and will afterwards hold a clinical meeting for medical practitioners on July 4th. The secretary of the conference is Miss Halford, Carnegie House, 117, Piccadilly, London, W. 1.

Fellowship of Medicine and Post-Graduate Medical Association

An advanced course in thoracic surgery will be given at the Brompton Hospital from Feb. 24th to 29th, and M.R.C.P. evening courses will be held as follows: chest and heart diseases at the Royal Chest Hospital (March 16th to April 4th); chest diseases at the Brompton Hospital (March 8th to April 4th); clinical and pathological demonstrations at the National Temperance Hospital (Feb. 25th to March 12th). An all-day course in orthopaedics has been arranged at the Royal National Orthopaedic Hospital (March 9th to 21st), and an afternoon course in neurology and psychopathology at the West End Hospital for Nervous Diseases (March 2nd to 27th). Week-end courses are to be held as follows: chest diseases at the Brompton Hospital (March 7th and 8th); clinical surgery at the Royal Albert Dock Hospital (March 14th and 15th); medicine at the Miller General Hospital (March 21st and 22nd); and urology at the All Saints Hospital (March 28th and 29th). Detailed syllabuses of all courses may be had from the secretary of the fellowship, 1, Wimpole-street, W. 1.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

- ROYAL SOCIETY OF MEDICINE**, 1, Wimpole-street, W.
MONDAY, Feb. 24th.
Odonology. 8 P.M. Mr. A. W. Wellings: Three Dental Abnormalities. Dr. C. F. Cosin: Aberrations of Calcium Metabolism in relation to Dental Disease.
TUESDAY.
Medicine. 5 P.M. Dr. G. W. Pickering: Obliterative Arterial Disease as it affects the Limbs. Prof. J. Paterson Ross and Prof. H. M. Turnbull will also speak.
Pathology. 8.15 P.M. for 8.30 P.M. Prof. J. W. McLeod: Data Bearing on Significance of *B. diphtheriae* Types accumulated in the last four years.
WEDNESDAY.
Comparative Medicine. 5 P.M. Prof. J. G. Wright: The Use of the Non-volatile Narcotics. Dr. Douglas Beifrage, Mr. B. Balfour-Jones, and Mr. Basil Hughes will also speak.
THURSDAY.
United Services: Psychiatry. 4.30 P.M. Colonel J. Healy-Spencer and Dr. E. Mapother: Functional Nervous Disease in the Fighting Services.
Urology. 8.30 P.M. Mr. R. H. O. B. Robinson: Horse-shoe Kidney. Mr. T. J. Millin: Impotence and its Surgical Treatment, with reference to New Operative Procedure. Mr. A. Elliot-Smith: Steinach II. Operation for Enlarged Prostate.
FRIDAY.
Disease in Children. 4.30 P.M. (Cases at 4 P.M.) Dr. Bernard Myers: 1. Essential Purpura Hemorrhagica. Dr. M. Price (for Mr. D. Levi): 2. Osteochondrodystrophy of Marqouie Type. Dr. R. C. Jewesbury: 3. Jaundice and Hepatic Cirrhosis. 4. Bilateral Foramina of the Parietal Bones. Dr. A. G. Maitland-Jones: 5. Tay-Sachs Disease. Dr. David Nabarro: 6 and 7. Congenital Syphilis showing Cutaneous Gummatous Lesions. Dr. W. P. H. Sheldon: 8. Anaemia with Bone Changes. Dr. Donald Bateman (for Dr. D. Paterson): 9-11. Epiphyseal Dysplasia Punctularis.
Epidemiology and State Medicine. 8.30 P.M. Sir William Hamer: The Endemic Influenza Prevalence of 1933-35.
Physical Medicine. 8.30 P.M. Mr. Francis Talbot and Mr. H. Mandivall: The Amelioration of Dental Sepsis by Physical Methods including Ultra-violet Irradiation and Ionisation.
MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.
MONDAY, Feb. 24th.—8.30 P.M., Lord Horder: Etiology and Treatment of *Bacillus coli* Infections of the Urinary Tract.
WEDNESDAY.—9 P.M., Dr. P. H. Manson-Bahr: The Differential Diagnosis of Diseases of the Colon (Dysentery and Colitis) and their Complications. (Second Lettsomian lecture.)
HUNTERIAN SOCIETY.
MONDAY, Feb. 24th.—9 P.M. (Mansion House, E.C.), Sir Lenthal Cheate: John Hunter's Time and Ours. (Hunterian oration.)
MEDICO-LEGAL SOCIETY.
THURSDAY, Feb. 27th.—8.30 P.M. (Mansion House, 26, Portland-place, W.), Mr. H. N. Linstead: Statutory Safeguards against Poisoning—the Work of the Poisons Board.
BRITISH PSYCHOLOGICAL SOCIETY.
WEDNESDAY, Feb. 26th.—8.30 P.M. (Institute of Medical Psychology, Malet-place, W.C.), Miss Margaret Ash-down: The Role of the Psychiatric Social Worker. Dr. W. J. T. Kimber and Dr. William Moodie will also speak. (Medical section.)
ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.
WEDNESDAY, Feb. 26th.—2.30 P.M. (11, Chandos-street, W.), Dr. E. Guttman: Experimental Psychoses induced by Mescaline.
ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY, Lisle-street, W.C.
WEDNESDAY, Feb. 26th.—4.15 P.M., Clinical Meeting. 5 P.M., Dr. F. A. E. Silcock: The Lady with the Green Hair and other Interesting Skin Cases.
LECTURES, ADDRESSES, DEMONSTRATIONS, &c.
ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.
THURSDAY, Feb. 27th.—5 P.M., Dr. E. L. Middleton: Industrial Pulmonary Disease due to the Inhalation of Dust, with Special Reference to Silicosis. (First Milroy lecture.)
UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, W.C.
FRIDAY, Feb. 28th.—5 P.M., Dr. Cecil Price-Jones: The Sizes of Red Blood Cells. (Sydney Ringer lecture.)
NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.
TUESDAY, Feb. 25th.—5.30 P.M., Dr. D. Evan Bedford: Radiological Examination of the Heart and Great Vessels.

- HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL**, N.W.
WEDNESDAY, Feb. 26th.—4 P.M., Dr. C. Rickword Lane: Clinical Pathology in General Practice.
HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.
THURSDAY, Feb. 27th.—3 P.M., Dr. Anthony Feiling: Demonstration.
NATIONAL HOSPITAL, Queen-square.
MONDAY, Feb. 24th.—2 P.M., Dr. Riddoch: Out-patient Clinic. 3.30 P.M., Dr. Critchley: Cerebral Vascular Disease.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Critchley: Cerebral Vascular Disease.
WEDNESDAY.—2 P.M., Dr. Martin: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.
THURSDAY.—2 P.M., Dr. Symonds: Out-patient Clinic. 3.30 P.M., Mr. Leslie Paton: Optic Neuritis.
FRIDAY.—2 P.M., Dr. Critchley: Out-patient Clinic. 3.30 P.M., Dr. Purdon Martin: Other Infectious Diseases of Nervous System.
HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C.
WEDNESDAY, Feb. 26th.—2 P.M., Dr. Donald Paterson: Bronchitis and Asthma. 3 P.M., Dr. Donald Bateman: Tests for Allergen Sensitivity.
 Out-patient Clinics daily at 10 A.M. and ward visits at 2 P.M.
LONDON SCHOOL OF DERMATOLOGY, 5, Lisle-street, W.C.
TUESDAY, Feb. 25th.—5 P.M., Dr. W. N. Goldsmith: Pigmentary Disorders.
THURSDAY.—5 P.M., Dr. A. Burrows: Malignant Conditions of the Skin.
FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Feb. 24th, to **SATURDAY**, Feb. 29th.—**INFANTS HOSPITAL**, Vincent-square, S.W. Mon., Wed., and Fri., 8 P.M., F.R.C.S. primary course.—**BROMPTON HOSPITAL**, S.W., All-day course in thoracic surgery.—**NATIONAL TEMPERANCE HOSPITAL**, Hampstead-road, N.W., Tues. and Thurs., 8 P.M., M.R.C.P. course.—**NATIONAL TEMPERANCE HOSPITAL**, Hampstead-road, N.W., Tues., 8.30 P.M., Mr. A. E. Porritt: Infection of Bones, and Thurs., Mr. R. Coyte: Large Intestine and Rectum.—**St. JOHN'S HOSPITAL**, 5, Lisle-street, W.C. Afternoon course in dermatology (open to non-members).—Courses are open only to members of the fellowship.
SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.
WEDNESDAY, Feb. 26th.—4 P.M. (St. James' Hospital, Ouseley-road, S.W.12), Dr. R. F. L. Hewlett: The Value of Blood Examinations.
WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.
MONDAY, Feb. 24th.—10 A.M., Skin Clinic. 11 A.M., Surgical Wards. 2 P.M., Gynecological and Surgical Wards, Eye and Gynecological Clinics. 4.15 P.M., Mr. Green-Armytage: Abdominal Pain in Pregnancy.
TUESDAY.—10 A.M., Medical Wards. 11 A.M., Surgical Wards. 2 P.M., Throat Clinic.
WEDNESDAY.—10 A.M., Children's Clinic and Wards. 11 A.M., Medical Wards. 2 P.M., Eye Clinic. 4.15 P.M., Dr. R. W. Ironside: Anesthesia.
THURSDAYS.—10 A.M., Neurological and Gynecological Clinics. Noon, Fracture Clinic. 2 P.M., Eye and Genito-urinary Clinics.
FRIDAY.—10 A.M., Skin Clinic, Medical Wards. 12 noon, Lecture on Treatment. 2 P.M., Throat Clinic. 4.15 P.M., Mr. Vlasto: Pyogenic Infections of the Ear.
SATURDAY.—10 A.M., Children's and Surgical Clinics, Medical Wards.
 Daily.—2 P.M., Operations, Medical and Surgical Clinics. The lectures at 4.15 P.M. are open to all medical practitioners without fee.
LEEDS GENERAL INFIRMARY.
TUESDAY, Feb. 25th.—3.30 P.M., Dr. Tattersall: Tuberculosis Demonstration.
LEEDS PUBLIC DISPENSARY.
WEDNESDAY, Feb. 26th.—4 P.M., Mr. L. N. Pyrah: The Treatment of Burns and Surgical Cutaneous Septic Conditions.
ANCOATS HOSPITAL, Manchester.
THURSDAY, Feb. 27th.—4.15 P.M., Dr. W. J. S. Reid: Polycythemia.
UNIVERSITY OF DURHAM.
SUNDAY, March 1st.—10.30 A.M. (Newcastle General Hospital), Prof. T. Beattie: Medical Ward Visit.
GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.
WEDNESDAY, Feb. 26th.—4.15 P.M. (Ear, Nose, and Throat Hospital), Dr. R. J. Watson: The Accessory Sinuses.

COMMITTEE ON NUTRITION.—At its first meeting on Feb. 15th the League of Nations committee on nutrition agreed on the general lines of the report to be prepared, took steps to obtain further information from governments and national authorities, and appointed a drafting committee which is to meet on May 4th, before a second session of the full committee to be held early in June. The committee unanimously adopted the report of the Technical Commission (which appeared in THE LANCET of Dec. 21st, 1935, p. 1434) which lays down the principles for a scientifically balanced diet for different ages and categories of human beings. This report is to serve as the basis for a big programme of research work in different countries.

NOTES, COMMENTS, AND ABSTRACTS

THE CINEMA IN MEDICINE

THE catalogue published¹ this week, of British medical films "of technical interest to medical practitioners and students," is a first attempt to collect under one cover British made films which are likely to be of value, not only in medical teaching but in medical practice. The British Film Institute, formed in 1933 on the recommendation of the Commission on Educational and Cultural Films, has an advisory committee on which are represented various Government departments, including the Ministry of Health and the Board of Education, and from this committee is set apart a panel of medical men interested in the use of films for instructional purposes. This medical panel undertook to collect information on existing medical films in this country, for this purpose addressing a questionnaire to all the medical schools and universities in Great Britain. The present catalogue is the result of this inquiry.

The films catalogued are classified under 9 sections and 42 subsections, which include most of the subjects taught in the medical curriculum. Against each is given title, date, author, width, silent or sound, length, name and address of owner, and (with excellent intent) whether suitable for undergraduate or post-graduate students, for nurses, or for public health propaganda. Supplements to the catalogue will be issued as need arises. There may be in existence medical films made by individuals or associations primarily for their own use but which may be of more general interest; the panel is anxious to secure full particulars of such films. In too many of the films viewed the medical panel noted with regret that the producers seemed to have had no clear idea of what it was they wished to demonstrate or at least of the best methods of demonstrating the points they wished to drive home. Sometimes an otherwise good film lost much of its teaching value for lack of appropriate captions and/or moving diagrams. The medical panel offers technical advice to those embarking on the production of medical films, in order to ensure the best use of the material available.

The use of films in all parts of the medical curriculum is increasing. Lecturers in such subjects as pharmacology, physiology, anatomy and biology, for example, frequently make films to illustrate their lectures, seeking in this way to save time and to retain the attention of large classes. While "speech" films may have their use in illustrating the operative technique of a distinguished surgeon, the panel considers that the field for such films in medical education is limited, and they have the disadvantage of thrusting into the background the personality of the teacher on the spot. A film, however good, is not intended to replace the lecturer but only to supplement his teaching. Slow-motion photography gets a good word from the panel. It provides a simple method of illustrating complicated technique and a means of studying movements which are ordinarily performed too quickly for the student to follow. In any case the lecturer should be able to stop a film when he wants in order to demonstrate details of a picture. There are projectors on the market in which it is possible to hold the picture without damage to the film or serious loss of light.

Most of the silent films are narrow ones. The 16 mm. film is non-inflammable and can be shown without danger in lecture hall or private house. For demonstration to a class of students at a moment's notice this type of film will probably be found the most useful for some time to come. The keen medical student will welcome the opportunity of supplementing his reading by looking at a film of the subject which he is studying. There are on the market at the present time projectors for 16 mm. silent

films, varying in price from £30 to as little as £6 15s., the latter being suitable for two or three persons in an ordinary room. The larger projectors can be hired for £1 a night. Even so the moving picture will often be beyond the student's purse, and commercial firms which produce films of medical or scientific interest might well arrange to show for a modest fee at their own theatres films of interest to the medical student. The British Film Institute would assist the student if willing to show in a theatre for a nominal fee a film which a student may have borrowed or have made himself. It is of real importance for medical education that the student should be able, outside of official lecture hours, to see films which will help him in that part of the medical curriculum which he happens to be studying.

GOTHIC WOMEN

THE nineteenth century woman was a mystifying creature. After a childhood of suppression and a girlhood in which vapidity was at a premium, she reached a maturity of wifely subservience and excessive reproduction. But if she survived the childbearing period with spirit unimpaired she usually came into her own as the tyrant grandmother—no fiction, but a valiant unscrupulous personage found surviving in many families in the early years of this century. How did she manage it? How could a youth of tight-lacing equip her for such heroic physical achievement; and when, during a much-occupied middle age, did she find opportunity to develop the qualities of a dictator? Can she be explained, like the older type of hospital matron, by saying: "If you trample on a person hard enough you have taught her all there is to know about trampling when her turn comes"? Perhaps she cannot be summed up in a formula at all, but at any rate much can be learnt about her from Dr. C. Willett Cunningham's "Feminine Attitudes of the Nineteenth Century"¹

Dr. Cunningham has an agreeable formula of his own. "Gothic Art," he says, "has been defined by an eminent authority, as 'the Art of constructing buttressed buildings.'" For him the nineteenth century woman is essentially Gothic. "How ingeniously her human qualities were buttressed by romantic ideals helping to sustain the great illusion! How carefully the fundamentals, on which her charms were based, were hidden! . . . Somewhere within that monolith was hidden a creature of flesh and blood." Nevertheless he remains baffled. He pursues her attitudes through the century rather like a terrier digging out a strange quarry; but when she is at last exhumed we find on his face the puzzled look of the terrier, wondering what this thing can be. What did she think of it all? Was she conscious of the pose or was she playing the game blindfold? Most disquieting of all, what was her real opinion of the Victorian man?

With illustration and quotation Dr. Cunningham traces the development of the Gothic attitude from the "cool, curious, and informed young woman" of the early years of the century, through the increasing romanticism of the 'thirties, the sentimental 'forties (when women were assured that "the opposite sex love, respect, and adore them and ever will, so long as they retain that inestimable jewel Virtue") to the Perfect Lady of the 'fifties. Thence Victorian woman declined through the revolting 'sixties (in a rebellious sense) the ornamental 'seventies, the symbolic 'eighties—illustrated by drawings of Girton girls in bustles and an academic aura—to the prude's progress in the 'nineties. And a charming history it all makes. Perhaps the reader will feel that not much has been proved, and that the light thrown on the scene has made the shadows look more impenetrable than ever, but he is bound to enjoy the extracts from novels and from

¹ British Film Institute, 4, Great Russell-street, London W.C.1. 1s.

magazines for young ladies, the advertisements of "beauty animated and vision preserved," of "the pneumatic tube coil . . . to all appearance an ordinary switch of hair," and one addressed to the Nobility and Gentry by Tiffin and Son, Bug-Destroyers to the Royal Family, who "beg to suggest the propriety of having this nuisance removed."

Appointments

BAILEY, K. C., M.B. Camb., has been appointed Assistant Medical Officer at Croydon Mental Hospital.
 BONNELL, JANE, M.R.C.S. Eng., Assistant Medical Officer at the Royal Eastern Counties Institution, Colchester.
 BOWES, R. K., M.D., M.S. Lond., F.R.C.S. Eng., Obstetric Physician in Charge of Out-patients at St. Thomas's Hospital, London.
 BROWN, A. I. P., M.B. Lond., Anaesthetist for the borough of Willesden.
 EBBAGE, G. B., M.R.C.S. Eng., Resident Surgical Officer at the Birmingham and Midland Eye Hospital.
 GILBERT, BARTON, M.D. Lond., F.R.C.S. Eng., Gynaecological Pathologist to the Chelsea Hospital for Women.
 LIVINGSTONE, G. H., M.B. Lond., F.R.C.S. Eng., Ear, Nose, and Throat Surgeon for the borough of Willesden.
 MACDONALD, DONALD, M.B., D.P.H., Resident Medical Officer at the Halifax Isolation Hospital.
 MAXWELL, JAMES, M.D., F.R.C.P. Lond., Assistant Physician to St. Bartholomew's Hospital, London.
 MELVILLE, A. G. G., M.B., D.R., F.R.C.S. Edin., Assistant Radiologist at the Victoria Infirmary, Glasgow.
 MILLER, A. C., B.Sc., L.M.S.S.A., D.O.M.S., Hon. Assistant Surgeon to the Sussex Eye Hospital.
 MONK, H. E., B.Sc., F.I.C., County Analyst and Bacteriologist for Worcestershire.
 PORTEOUS, M. I., M.B. Edin., D.P.H., Assistant Medical Officer of Health for the county borough of Warrington.
 SHAWCROSS, E. W. H., M.R.C.S. Eng., D.M.R.E., Radiologist at the Samaritan Free Hospital for Women, London.
 SPENCE, A. W., M.D., M.R.C.P. Lond., Assistant Physician, and Assistant Director of the Medical Professorial Unit, St. Bartholomew's Hospital, London.
 TYRRELL, T. M., M.B. Camb., F.R.C.S. Eng., Assistant Hon. Surgeon to the Royal Eye Hospital, London.
 WRIGLEY, A. J., M.D. Lond., F.R.C.S. Eng., Obstetric Physician to St. Thomas's Hospital, London.
 YEO, K. J., M.B. Camb., D.M.R.E., Hon. Radiologist to the Royal Northern Hospital, London.

Vacancies

For further information refer to the advertisement columns
 Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.
 Benenden, Kent, National Sanatorium.—Jun. I.I.P. At rate of £150.
 Birmingham Ear and Throat Hosp.—Third I.I.S. At rate of £150.
 Birmingham, Queen's Hosp.—Sen. Res. Anaesthetist. £70-£100.
 Birmingham, St. Chad's Hosp.—Jun. Res. M.O. At rate of £150.
 Blackburn, Queen's Park Hospital and Institution.—Res. Jun. Asst. M.O. At rate of £150.
 Bolton Royal Infirmary.—Res. Surg. O. £250.
 Bradford Royal Infirmary.—H.S. At rate of £135.
 Brighton, Royal Sussex County Hospital, and Howe General Hospital.—Hon. Physiotherapist. Also Hon. Med. Reg.
 Bristol University.—Asst. Clin. Path. £375.
 British Postgraduate Medical School, Ducane-road, W.—Two First Asssts. for Dept. of Surgery. Each £250-£500.
 Cambridge, Addenbrooke's Hospital.—H.S. At rate of £130.
 Cancer Hospital, Fulham-road, S.W.—Res. M.O. for Radium Dept. At rate of £100.
 Cardiff, Welsh National School of Medicine.—Lord Merthyr Research Scholarship. £200. Also Mrs. John Nixon and Ewen Maclean Research Studentships. Each £150.
 Central London Ophthalmic Hospital, Judd-street, W.C.—Sen. and Jun. H.S. £120 and £100 respectively.
 Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Two Asssts. in Out-patient Dept.
 Charing Cross Hospital, W.C.—Surg. Reg. £150. Also Obstet. Reg. and Registrar. Each £100.
 Chester, County Mental Hospital.—Jun. Asst. M.O. £350.
 City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Physician to In-patients.
 Dewsbury and District General Infirmary.—Second H.S. £150.
 Dreadnought Hospital, Greenwich, S.E.—H.P. and H.S. Each at rate of £110.
 Edinburgh, National Association for the Prevention of Tuberculosis.—Secretary-General. £600.
 Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Clin. Asssts. to Medical Dept.
 Exeter, Royal Devon and Exeter Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.
 Guildford, Royal Surrey County Hospital.—H.S. Also H.P. and Cas. O. Each at rate of £150.
 Harrogate and District General Hospital.—H.P. and Cas. O. Also H.S. Each at rate of £150.
 Herefordshire General Hospital.—H.P. Also H.S. and Cas. O. Each at rate of £100.
 Hospital for Tropical Diseases, Gordon-street, W.C.—H.P. At rate of £120.
 Hospital of St. John and St. Elizabeth, 60, Grove End-road, N.W. Surg. Reg. £100. Also Clin. Asst. to Ear, Nose, and Throat Dept.

Huddersfield Royal Infirmary.—Cas O. £200. Also H.S. At rate of £150.
 Kesleven County Council.—M.O.H. £1000.
 Leicester County Sanatorium and Isolation Hospital, Markfield.—Jun. Res. M.O. At rate of £300.
 Leicester Royal Infirmary.—Res. Anaesthetist. At rate of £150.
 Cas. O., H.S., and H.P.'s. Each at rate of £125. Also Jun. Cas. O. At rate of £100.
 Liverpool, Bootle General Hospital.—H.P. and H.S. Each at rate of £150.
 Liverpool, Hospital for Consumption and Diseases of the Chest, Mount Pleasant.—Res. M.O. £150.
 Liverpool, Royal Babies Hospital.—Res. M.O. At rate of £90.
 Liverpool, Royal Children's Hospital.—Res. Surg. O. for Heswall Branch. At rate of £120.
 London Homœopathic Hospital, Great Ormond-street, W.C.—Hon. Surgeon. Also Hon. Asst. Surgeon.
 Maidenhead Hospital.—Hon. Physician.
 Maidstone, West Kent General Hospital.—H.P. £175.
 Manchester, Duchess of York Hospital for Babies.—Sen. and Jun. Res. M.O.'s At rate of £125 and £75 respectively.
 Manchester Royal Children's Hospital, Gartside-street.—Two Asst. M.O.'s for Out-patients' Dept. Each at rate of £150.
 Manchester Royal Infirmary.—Jun. Asst. M.O. for Radiological Dept. £350.
 Manor House Hospital, Golders Green, N.W.—Jun. M.O. £200.
 Mellon, Suffolk, St. Audry's Hospital.—Jun. Asst. M.O. £350.
 Middlesbrough County Borough.—M.O.H. for Maternity and Child Welfare. £350.
 Middlesex County Council.—Tuberculosis Sanatorium, South Mimms. Deputy Med. Supt., &c. £450.
 Mount Vernon Hospital, Northwood.—H.S. At rate of £150.
 Norwich, Norfolk and Norwich Hospital.—Res. M.O. £250. Also Res. Orthopaedic O. £200.
 Nottingham General Hospital.—H.S. for Fracture and Orthopaedic Depts. £300. Also H.S. to Ear, Nose, and Throat Dept. At rate of £150.
 Plymouth City General Hospital.—Jun. Asst. M.O. £250.
 Plymouth, Prince of Wales's Hospital, Greenbank-road.—H.S. and H.P. Each at rate of £120.
 Preston, Biddulph Grange Orthopaedic Hospital.—Jun. H.S. At rate of £200.
 Preston Royal Infirmary.—H.S. for Obstet., Eye, and Ear Wards. £150.
 Preston, Sharoe Green Hospital.—Sen. and Jun. Asst. Res. M.O.'s. At rate of £200 and £100 respectively.
 Prince of Wales's General Hospital, N.—Res. Jun. H.P. and H.S.'s. Each at rate of £90. Also Hon. Med. and Surg. Regs. Each £100.
 Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.—H.S. At rate of £100.
 Queen's Hospital for Children, Hackney-road, E.—H.P. and Cas. O. Each at rate of £100.
 Rhondda Urban District Council.—Asst. M.O. £500.
 Rochdale, Birch Hill Hospital.—Jun. Res. M.O. At rate of £200.
 Rochdale Infirmary and Dispensary.—Second H.S. £150.
 Rotherham Hospital.—Sen. H.S. or P. £200. Also Cas. H.S. £150.
 Royal Army Medical Corps.—Commissions.
 Royal College of Surgeons of England.—Election to Court of Examiners.
 Royal Eye Hospital, St. George's-circus, S.E.—Part-time Pathologist and part-time Bacteriologist. Each £100. Also Sen. H.S. and two Asst. H.S.'s. At rate of £150 and £100 respectively.
 Royal Masonic Hospital, Ravenscourt Park, W.—Res. Surg. O. At rate of £250.
 St. Bartholomew's Hospital Medical College.—Sen. Demonstrator in Dept. of Pathology. £400.
 St. George's Hospital, S.W.—Asst. Bacteriologist. £500.
 St. Leonards-on-Sea, Buchanan Hospital.—Jun. H.S. £125.
 St. Peter's Hospital for Stone, &c., Henrietta-street, W.C.—H.S. At rate of £75.
 Shorham-by-Sea, Southlands Hosp.—Second Asst. Res. M.O. £300.
 South Shields, Ingham Infirmary.—Jun. H.S. £150.
 Stockport Infirmary.—H.P. £150.
 Stoke-on-Trent, Stanfield Sanatorium.—Res. M.O. £250.
 Swansea County Borough.—Asst. M.O. £500.
 Warrington County Mental Hospital, Winwick.—Asst. M.O. £500.
 West London Hospital, Hammersmith-road, W.—H.P. and H.S. to Spec. Depts. Each at rate of £100.
 Whitechapel Venereal Diseases Clinic, Turner-street, E.—Director. £1250.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Wrexham (Denbigh).

Births, Marriages, and Deaths

BIRTHS

GRATRIX.—On Feb. 8th, at Redcliffe-gardens, South Kensington, S.W., the wife of Dr. William H. Gratrix, of a daughter.
 ORME.—On Feb. 6th, at Bidston, Matlock, the wife of Dr. C. L'Estrange Orme, of a son.
 SMITH.—On Feb. 8th, at Topsham, Devon, the wife of Dr. E. H. Protheroe Smith, of a daughter.
 THROWER.—On Feb. 10th, at Belvidere, Weymouth, the wife of William Rayner Thrower, M.D., M.R.C.P. Lond., of a son.

DEATHS

DONALDSON.—On Feb. 14th, at a Coventry nursing-home, James Smith Donaldson, M.B. Glasg., of Balsall Commou, aged 37 years.
 GUBB.—On Feb. 3rd, suddenly, at Mustapha Supérieur, Algiers, Alfred S. Gubb, M.D. Paris, M.R.C.S. Eng., D.P.H.
 N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

ON THE PROPHYLACTIC ACTION OF
"BAYER 205" AGAINST THE
TRYPANOSOMES OF MAN

CONCLUDING OBSERVATIONS

BY H. LYNDBURST DUKE, O.B.E., M.D., Sc.D. Camb.

DIRECTOR OF THE HUMAN TRYPANOSOMIASIS RESEARCH
INSTITUTE, ENTEBBE, UGANDA

THE preliminary paper of this research was published in this journal in June, 1934. In that paper a brief summary was given of the work already done on Bayer 205 as a prophylactic against the trypanosomes of man, but no reference was made to the work of Fourche and Haveaux (1931), of which at the time I was not aware. These investigators concluded that preventive treatment should be restricted to the healthy while the infected are undergoing cure, doubtful cases being rigorously excluded; that at least two doses of Bayer 205 should be employed; and that the preventive effect can be relied upon for from six to seven months at most.

In December, 1934, there appeared a paper by Corson on the action of Bayer 205 on *Trypanosoma rhodesiense* in white rats infected by tsetse flies (Corson b). The author, to use his own method of presenting his results, found that a dose of 0.015 g. per kg. body-weight did not protect these animals for 21 days, and that a dose of 0.03 g. failed to protect for 40 days. He concluded that the drug has a strong prophylactic action in animals and may be presumed to have the same in man; also that the action varies somewhat in degree in individual animals of the same species, and it may be expected that this will also occur in man. He also remarked, "The chief difficulty seems to be the question whether the drug might cause such alteration of the virulence of the trypanosomes as to make diagnosis difficult."

THE PRELIMINARY INVESTIGATIONS

The following is a summary of the investigations already described in THE LANCET (1934, 1., 1336).

Two groups of native volunteers were taken. The first consisted of 4 men, A., B., C., E., who had recently been experimentally infected with *T. rhodesiense* and then treated with Bayer 205 immediately trypanosomes were seen in their blood (i.e., 8-11 days after the act of infection). Each man had received six doses of Bayer 205 in 1.0 g. doses intravenously at intervals of a few days. The second group comprised 3 virgin volunteers, I., M., and Q., each of whom received a single intravenous injection of 1.0 g. Bayer 205. In every instance exposure to infection was by the bite of tsetse known to be infective to man, 7 clean volunteers being used as controls. The results of the investigation were as follows: The men A., B., C., and E. resisted *T. rhodesiense* for at least 190, 180, 182, and 105 days respectively, these figures relating to their last exposure to infection. Volunteer B., who was still protected at the 180th day against *T. rhodesiense*, was infected by *T. gambiense* between the 208th and 212th days after the last dose of Bayer 205. Volunteers I., M., and Q., who received a single dose, were protected against *T. rhodesiense* for at least 111, 113, and 108 days. Volunteer M., when exposed to *T. gambiense* on the 145th day, became infected. Those who escaped infection—namely, A., C., I., and Q., remained under observation in perfect health for more than 18 months, after which all of them were employed again.

In the discussion that followed it was suggested that the degree of protection conferred might be to some extent

proportional to the quantity of Bayer 205 administered, a conclusion also reached by Browning and Gulbransen (1934) in their work on *T. brucei* in mice. It appeared possible also that the protection conferred by Bayer 205 was greater against *T. rhodesiense* than *T. gambiense*; either because the greater biological adaptation of *T. gambiense* to man rendered that trypanosome in some way less susceptible to the drug in man, or because of the greater susceptibility of *T. rhodesiense* to the drug. Findlay (1930) records that Moranyl is less efficient against *T. gambiense* than *T. rhodesiense*.

Two experiments performed with monkeys suggested that the greater the susceptibility of the vertebrate to the trypanosome the less efficient the protection conferred by the drug; in other words, that an animal's natural resistance helps the Bayer 205 to stave off the trypanosome.

The use for the first time of native volunteers on a large scale involved difficulties that have since been largely overcome, and explained the inclusion of the men of Group I. These were the first volunteers to come forward and were willing to serve again. It was realised that there were objections to their employment—i.e., the large amount of Bayer 205 administered and the possible immunising effect of the liberation of antigen following the destruction of the trypanosomes by the first dose. But time and opportunity were pressing and no one else was available.

The Inquiry Continued

The full extent of the protection conferred by the drug against *T. rhodesiense* was not determined as no protected volunteer succumbed to that trypanosome, the only 2 men who were infected falling to *T. gambiense*. In the course of the present investigations, several of the volunteers after having been infected and treated were later on again exposed to infection. Table I. gives brief details of their exposure to reinfection:—

TABLE I
Re-exposure of Experimentally Infected Volunteers to
Infection, at 6-16 Months after Cessation of Treatment

Volunteer.	Trypanosome and date of first infection.	Last dose of treatment.	Trypanosome and date of subsequent infection.
A.	rhodesiense (30.viii.33)	29.ix.33	rhodesiense (15.vii.35)
B. (1)	rhodesiense (23.viii.33)	30.ix.33	—
B. (2)	gambiense (28.iv.34)	29.vi.34 (tryparsamide)	gambiense (22.vi.35)
D.	rhodesiense (8.iii.34)	26.iv.34	rhodesiense (7.v.35)
E.	rhodesiense (6.ix.33)	13.xii.33	rhodesiense (1.iii.35)
M.	—	1.0 g. Bayer 205 prophylactic, 13.xii.33	—
	gambiense	6.vi.34 (tryparsamide)	rhodesiense (2.vii.35)
K.	rhodesiense (16.iii.34)	23.iv.34	rhodesiense (23.vi.35)
Z. A.	gambiense (12.iv.34)	9.v.34 (tryparsamide)	rhodesiense (10.vi.35)
A. A.	gambiense (18.ii.35)	3.iv.35 (tryparsamide)	rhodesiense (15.x.35)
E. E.	gambiense (21.ii.35)	5.iv.35 (tryparsamide)	gambiense (18.x.35)

The evidence presented in the two Tables of this paper suggests that the maximum immunity is obtained from the frequently repeated destruction of living trypanosomes in an organism initially protected by Bayer 205.

The great majority of the volunteers infected with *T. rhodesiense* and treated with Bayer 205 experienced, immediately after their first injection, a rise of temperature to 104-106° F., falling in 36-48 hours to normal where it continued. From a

study of the charts of all the men employed, it would appear that the patient's reaction when *T. gambiense* is treated with tryparsamide is less severe than that following treatment of *T. rhodesiense* with Bayer 205.

A striking exception to the usual response to treatment was shown by one of the volunteers.

He was admitted with a temperature of 103° F., and received his first dose of Bayer 205 when his temperature was 100° F., after which for 48 hours it fluctuated between 99° F. and 101° F. Then, following a second Bayer 205 injection, the temperature rose to 105° F. and remained remittent around that level for nine days, during which another injection of Bayer 205 and two of quinine were given, malaria having been found in his blood. The fourth dose of Bayer 205 was followed by yet another rise to 105° F., and 36 hours later the temperature fell to normal and remained there.

This extraordinary course cannot, I think, be attributed to the coincident malaria, for a number of the volunteers had this parasite simultaneously with trypanosomes. It is, rather, an example of an idiosyncrasy either for the products of the destruction of the trypanosomes or for the drug itself.

In none of the men of Table I. was the incubation period prolonged. These reinfections show that any immunity conferred by a brief (10–15 days) infection with *T. rhodesiense* or *T. gambiense* followed by a course of six injections with Bayer 205 or tryparsamide, does not persist for as long as 6–16 months.

CONTROL MEASURES DURING THE INVESTIGATION

It is of course necessary to prove the infectivity of the tsetse before they bite man; and similarly when the syringe is used, the inoculum must be proved to be infective to animals when it is introduced into the volunteer. The former process takes up time and so increases the likelihood of infective flies dying before they have bitten man. But in addition to ordinary routine precautions against the casual infection of experimental animals (described elsewhere, Duke, 1934), the employment of man introduces new complications. Natives differ individually in their natural resistance to trypanosomes, and strains of human trypanosomes, particularly *T. rhodesiense*, may alter from time to time in their pathogenicity to man. It is impossible to present all experimental details, and the reader must accept the assurance that the strains used in these experiments were indeed infective to man, as proved by control experiments on man at frequent intervals.

Another difficulty has been the provision of an adequate number of gland-infected flies with which to ensure exposure of the volunteers to infection. In the experiments recorded in this paper over 16,000 flies were dissected of which 120 had gland infections, more than half of these last dying before they were ever fed on man.

It was hoped during these experiments to secure decisive evidence whether there is any essential difference between the results obtained by fly-bite and by syringe infection, but this proved impracticable. The former method is to be regarded as the more reliable in assessing the value of the prophylactic, as it is the method encountered in nature. I have discussed elsewhere (Duke, 1935) the two modes of infection and, in opposition to certain investigators, still believe that subcutaneous inoculation of infected blood may give misleading results, especially when the pathogenicity of a trypanosome to man is under investigation. In these experiments the syringe method has been used mainly under constraint, in default of a sufficient number of gland-infected flies.

And now a word to the impatient. The investigation, from whatever angle, of the behaviour of human trypanosomes in man involves contact with a number of different factors. In the present inquiry, for example, the following have to be borne in mind: differences in man's individual resistance to trypanosomes; the characters of different strains of trypanosomes; the immunising effect (so far quite

unknown) of repeated small inoculations of living metacyclic or blood trypanosomes into an individual still under the protection of Bayer 205; and the rate and extent of absorption and elimination of the drug in the individual. All these are variables, and we must therefore be content for the time being with rough indications rather than accurate scientific conclusions. Indeed the more one studies the trypanosomes of the *brucei* group in relation to man himself the more apparent becomes our ignorance of his true place in their economy in nature.

EXPLANATION OF TABLE II

Table II. sets forth the details of the exposure and response of the volunteers to infection.

Of the 53 gland-infected flies actually used in these experiments, 34 came from different boxes—i.e., one infective fly per box; the other seven boxes each contained 2–4 infective flies. Each single box of flies, before being placed on a volunteer had infected at least one clean animal and often more. Fly No. 15, for example, in the course of its career of 86 days, infected in turn a guinea-pig, 2 unprotected volunteers, 3 antelopes, and a monkey. Each infective fly is distinguished in the Table by a number, and where more than one occurred in the same box a letter is added. For obvious reasons it was impossible to test every fly on a separate clean volunteer, but the following were actually proved able to infect man: Nos. 1, 2a, b, c, and d, 3a and b, 5, 8, 10, 14, 17, and 18a, b, c, and d, 33a and b, and 41. The untested majority all carried strains known to be readily infective to man.

In the course of investigations at this laboratory and particularly during the last six months, flies infective with certain lines of *T. rhodesiense* have been found to be non-infective to unprotected volunteers. Such trypanosomes have therefore been excluded from the Table. Only two strains of *T. rhodesiense* have been used in these experiments and great care has been taken throughout only to use lines of these two strains that have given recent evidence of pathogenicity to man. More exact control than this was not possible. Ideally, each individual fly should be tested independently on several volunteers—obviously an unattainable ambition. Work of this kind is full of surprises, and there have been incidents here and there in the course of these and other kindred investigations which do indeed suggest that with "borderline" strains individual flies may differ in their ability to infect man. The evidence for this is admittedly slight, but the possibility cannot be dismissed merely because it appears to be improbable.

The volunteers were exposed to infection by one of two methods; either by allowing infective flies to bite them, or by subcutaneous inoculation of blood containing living trypanosomes. The method used is shown in the columns under "exposure to infection." Every inoculation recorded in the Table was accompanied by controls, all of which were promptly infected. All the inoculations of salivary glands of infective flies were likewise controlled, and none is recorded unless the control rat or guinea-pig became infected with the opposite gland of the same fly. The inoculation of salivary glands was always additional to the exposure by fly-bite recorded in column 4.

The incubation period (in days) is calculated to the day when trypanosomes were first found in stained thick films of the blood. The dose of Bayer 205 received by each volunteer is shown under his designation in column 1: Thus, 1.0 g. = a single intravenous injection of 1.0 g. of Bayer 205, irrespective of body-weight; 2.0 g. = a single dose of 2.0 g.; 1.0 + 1.0 g. = two doses of 1.0 g. each, separated by 21 days. No attempt was made to standardise the amount of Bayer 205 administered according to the weight of the volunteer, and in practice it is unlikely that this would be done. The net weight of each man in kilos is shown in column 1 of the Table; it will be noted that only two touch 10 st. (63.6 kg.).

Every fly before being placed on the volunteer was either starved for 72 hours and then given one opportunity of feeding, or starved for 48 hours and then put on him on the two succeeding days. All flies that refused to feed were at once killed and dissected.

Trypanosomes: R.=rhodesiense; G.=gambiense. inc.=incubation. c.c.=cubic centimetres.

REMARKS

K. K.—The short incubation period suggests that the previous infection was established and dormant.
 Z. M.—135th-141st and 146th-148th day: inoculated with gland of 28 and 22a respectively. Trypanosomes first seen in Z. M.'s blood on 188th day; no symptoms from 148th-179th days; see text, "cryptic infections."
 Z. F.—171st day: inoculated with gland of 13. 252nd-253rd day: Ditto 21. 262nd-263rd day: Ditto 24. 320th-323rd day: Ditto 38 and 40. 365th day: Lumbar puncture; cells 4.5 per cm.
 Z. G.—120th-121st day: inoculated with gland of 18b. 149th-150th day: Ditto 22b.
 P. P.—223rd day: Acute general and local symptoms and trypanosomes 6 days after the blood inoculation. Probably also cryptic infection due to last fly-bite (see text).

G. G.—166th day: inoculated with gland of 8 and 9. 187th day: Ditto 3b.
 H. H.—224th-226th day: inoculated with gland of 18a and 26.
 Z. K.—Symptoms and trypanosomes on 219th day. See text discussion cryptic infections.
 Z. L.—152nd day: control clean volunteer also inoculated and infected after 12 days' incubation.
 Z. N.—153rd-156th day: inoculated with gland 18d, 19. 180th day: Ditto 22c. 201st-204th day: inoculated with gland 31. Small painful swelling on area of fly-bites.
 Z. I.—Trypanosomes first found in Z. I.'s blood on 233rd day; see text, discussion on cryptic infections.

SUMMARY OF THE INFORMATION CONVEYED BY TABLE II

(1) Nine volunteers received a single dose of 1.0 g. Bayer 205; five others a single dose of 2.0 g.; and four others two doses of 1.0 g. each, separated

by an interval of 21 days. All injections were given intravenously.

(2) Of those receiving 1.0 g., four were infected at their first exposure, 92, 105, 92, and 73 days after the administration of the drug, two falling to

T. gambiense and two to *T. rhodesiense*. The remaining five were protected for 120, 123, 97, 190, and 327 days respectively. Against *T. gambiense* the minimal periods of protection were 120, 111, and 97 days, and against *T. rhodesiense* 123, 73, 327, and 190 days. It must however be realised that as most of the later exposures were carried out with *T. rhodesiense*, the majority of the figures for *T. gambiense* are very conservative estimates.

(3) Of those receiving 1.0+1.0 g. none were infected at their first exposure. Protection against *T. gambiense* lasted 169 and 187 days, and against *T. rhodesiense* 171, 206, and 164 days.

(4) Of those receiving 2.0 g. none were infected at their first exposure. Protection against *T. gambiense* lasted 128 and 153 days, and against *T. rhodesiense* 163, 103, 152, 180 and 179 days.

(5) No more evidence has been secured about the relative effect of Bayer 205 on each of the two human trypanosomes, because, owing to lack of flies carrying *T. gambiense*, most of the later exposures were made with *T. rhodesiense*.

(6) As a general rule when infection did ensue it developed normally. There were however certainly three and possibly five examples of delayed or "cryptic" infection (volunteers Z. K., Z. I., Z. M., P. P., and K. K.) which are discussed below.

(7) The Table affords some support of the belief that 2.0 g. of Bayer 205 confers greater protection than 1.0 g.

(8) The most arresting result is the protection conferred upon volunteer Z. F., who was exposed to a long succession of gland-infected flies carrying *T. rhodesiense*, several of which had actually been proved to be infective to man, and all carrying strains known to be strongly pathogenic.

The single fly (41 of Table II.) which bit this man on the 327th day, had infected a clean volunteer a few days previously. The fly was dissected a few hours after biting Z. F. and was full of his blood; its glands were swarming with trypanosomes. On the day before trypanosomes appeared in Z. F.'s blood, lumbar puncture was performed. A perfectly clear fluid emerged under very slightly increased pressure. Examined by the Ross-Jones test the fluid contained no excess of globulin; and the lymphocyte count was 4.5 per c.mm. On the following day, the 16th after his last exposure, Z. F. complained of headache, his temperature was 99.5° F. and trypanosomes were found in his blood. This was the first occasion in his long experimental service that Z. F. complained of any symptoms. The condition of the cerebro-spinal fluid and the subinoculations of his blood into monkeys show that he had in truth escaped infection until the last subcutaneous inoculation.

An experiment was carried out to determine whether Z. F.'s blood possessed any action against *T. rhodesiense*.

Eight white rats were inoculated on Sept. 6th, 1935, with 0.25 c.cm. citrated blood of a monkey infected with *T. rhodesiense*. Trypanosomes appeared in the peripheral blood of all the rats on Sept. 10th. On the 12th three of the rats (weighing respectively 184, 217, and 207 g.) received a subcutaneous inoculation of 0.5 c.cm. serum of a normal European; three others (weighing 184, 190, and 169 g.) received 0.5 c.cm. serum of Z. F., 321 days after his injection of Bayer 205; and the remaining two (weighing 167 and 165 g.) were kept as controls. No apparent effect was produced by either serum on the number of trypanosomes appearing daily in the peripheral blood or on the duration of the disease. The European serum rats died on Oct. 7th, 11th, and 17th; those receiving Z. F.'s serum on Oct. 2nd, 7th, and 14th; and the two controls on Oct. 8th. As the untreated disease lasted for 32 days in rats, it is considered these limited observations

reveal no difference in the protective power of the two human sera tested.

General Discussion

MODE OF INFECTION AND STRENGTH OF INOCULUM

It has not been possible during this research to learn anything definite about the significance of the number of trypanosomes introduced or to contrast the two methods of infection. We know now that a single fly can infect man with either *T. gambiense* or *T. rhodesiense*, and it is highly probable that this is the way he ordinarily becomes infected in nature. Certainly it is extremely unlikely that anyone will be so unfortunate as to be bitten simultaneously by three or four gland-infected flies as were several of the volunteers on several occasions during these experiments.

Various observers have examined this question using the blood forms of the trypanosome, the most recent being Corson, who decided that the number of trypanosomes in the inoculum makes very little if any difference to the result (Corson (c)). The opinion of the volunteers themselves is that the syringe is the more deadly of the two modes of infection, but they are no doubt biased by the greater local discomfort it causes. Some of the "arms" that followed subcutaneous injection were really impressive, as also was the rapidity with which the local inflammation disappeared with trypanocidal treatment.

Unfortunately, it is impossible to compare the two methods of infection in the same subject, and I can only reiterate my belief that the inoculation of 1 c.cm. of citrated blood containing say from 1-3 trypanosomes per microscopic field ($\frac{1}{2}$ obj. \times 2 oc.) is a more severe test than the bite of a single fly infective with the same strain.

CRYPTIC INFECTIONS

In Table II. there are four instances of what may be described as cryptic infections among these volunteers—i.e., P. P., Z. I., Z. K., and Z. M.—and K. K. is possibly another example. With volunteer P. P. it is true the evidence is not absolutely conclusive. This man developed typical symptoms of infection 6 days after an injection into his forearm of blood infected with *T. rhodesiense*. On the third day after this inoculation, the arm being then considerably swollen, a small tender swelling appeared on his leg, on the area of skin where the last batch of infective flies had bitten him 21 days before.

Now a small tender swelling at the bite of an infective fly is not an uncommon symptom in volunteers infected by this method. The appearance of this swelling, therefore, together with the short period (6 days) elapsing between the injection of the blood and onset of symptoms, suggest that there was an undetected focus of living trypanosomes persisting at the site of the fly-bite and that this focus lit up during the general disturbance caused by the subsequent injection of infected blood. In support of this conclusion is the fact that in a control untreated volunteer who was inoculated simultaneously from the same inoculum as P. P., the first symptoms did not develop until the 15th day after inoculation. Volunteer K. K. is possibly another instance of the same kind. Volunteer P. P. when treated with Bayer 205 reacted in a typical manner, the temperature rising to 106° F. after the first injection and falling to normal within 36 hours. K. K., infected with *T. gambiense* and treated with trypanamide, exhibited a very mild febrile reaction

during his treatment, 101° F. being the highest recorded.

Trypanosomes were first found in Z. I.'s blood 33 days after his infection with blood containing *T. rhodesiense*; he denied feeling indisposed at any time and his temperature when the "positive" slides were taken was normal. His blood infected a monkey 19 days after his own infection. In this case, also, a second inoculation of *T. rhodesiense* was made before the original infection was diagnosed—i.e., 21 days later. When admitted to hospital this man's temperature remained for 48 hours between subnormal and 99° F. before treatment. After the first two injections of Bayer 205 (which produced no rise) the temperature remained normal for 7 days, rising for a few hours to 101° F. after the third injection, after which no further rise occurred.

The other two cases were more definite.

Volunteer Z. K. was inoculated with blood containing *T. rhodesiense* on two occasions after his actual infection with *T. gambiense* and before that infection had been diagnosed, the dates of the three inoculations being: *T. gambiense* on July 19th, 1935, and *T. rhodesiense* on August 12th (afternoon) and Sept. 9th. He first showed the characteristic early symptoms of trypanosomiasis on Sept. 20th, 11 days after the last inoculation of *T. rhodesiense* and two months after his inoculation with *T. gambiense*. His blood infected a clean monkey on August 12th (morning) and again on Sept. 3rd, on both occasions with *T. gambiense*; but until Sept. 20th he denied feeling any discomfort whatever. On admission into hospital his temperature was 102° F., and 12 hours after the first injection of Bayer 205 reached 105° F., dropping to normal 12 hours later. On the fifth and sixth days it rose to 99° F., tryparsamide was administered, and no further rise occurred.

Volunteer Z. M. was bitten by several gland-infected flies carrying *T. rhodesiense* between August 1st and 14th. He remained apparently in perfect health until Sept. 21st, when on close questioning he admitted a slight headache overnight. Trypanosomes were found in stained thick films of his blood on Sept. 23rd, and his temperature (taken four-hourly) during the ensuing 48 hours twice rose from normal to 99° F. On Sept. 9th and 16th his blood infected clean monkeys with *T. rhodesiense*. During his first two days in hospital his temperature reached 99° F. twice; the first two doses of Bayer 205 produced no further rise, but on the seventh day 101° F. was recorded for a few hours.

The trypanosomes isolated from both Z. K. and Z. M. were found to be readily transmissible by *G. palpalis*.

To balance the impression made by these cases, in all of which Bayer 205 may possibly have played in part, an example must be cited from another investigation. A similar kind of infection occurred in a volunteer (O.) who had been experimentally infected some 20 months previously with *T. rhodesiense* and treated in the usual way with Bayer 205, the last dose being given on Dec. 6th, 1933.

His temperature reaction on that occasion showed the typical rise to 105° F. after the first dose and then a rapid drop to normal. On August 7th, 1935, 610 days after the last dose of his course of Bayer 205, this man was inoculated with the blood of a guinea-pig infected with a strain of *T. rhodesiense* known to be of uncertain pathogenicity to man.

Two other adequately controlled injections of this strain into normal and untreated volunteers had failed, and in this man an entirely symptomless infection was revealed by an inoculation of his blood into a clean monkey on August 29th, 22 days after his exposure.

In the course of daily examinations of stained thick films of the blood of this monkey, trypanosomes were found first on Sept. 19th, 1935, and were subsequently diagnosed as *T. rhodesiense*. On Sept. 9th, still claiming to be in perfect health and his infection still undetected, the man

received another inoculation of same strain, this time from a monkey. On the 18th his blood again infected a clean monkey with *T. rhodesiense*, the incubation period in the monkey being nine days. Thick stained films of the man's blood were taken and examined on Sept. 23rd, 24th, 25th, 26th, and on the 27th very scarce trypanosomes were seen for the first time, and again on succeeding days until treatment was started. His temperature, taken twice daily, first rose above normal on Oct. 3rd, and his health according to his repeated asseverations remained excellent until that date, when he was taken into hospital. On admission he registered 99° F., and after the first injection of Bayer 205 the temperature was 99.6° F. and thenceforward normal.

The fact that the strain of trypanosomes responsible for this man's infection had already completely failed to infect 2 virgin volunteers shows that his previous infection and its treatment with Bayer 205 had left no trace of protection against his subsequent infection twenty months later.

This case shows that cryptic infection of man is not solely dependent on Bayer 205, but that it may arise also from the interaction between the natural resistance of the individual and the invading trypanosome. Cryptic infection must in fact be recognised as one of the forms assumed by human trypanosomiasis, and may occur with both of man's trypanosomes.

It was deemed unjustifiable to postpone treatment of these 3 men in order to watch the course of events. All 6 (Z. K., Z. M., P. P., K. K., Z. I., and O.) responded readily to treatment, there being no suspicion of drug-resistance in the trypanosomes in their blood.

CONDITIONS FOR DEVELOPMENT OF CRYPTIC INFECTIONS

The employment of volunteers on a large scale has thrown new light on certain phases of the early stages of trypanosome infections in man. The possibility of the occurrence of cryptic infections in man has long been debated, and Duren and Van den Branden (1934) have recently described two cases of *T. gambiense* of this nature in Europeans, one of which is peculiarly significant. The patient, who had quitted Africa 18 months previously, consulted the authors, complaining of mild lassitude and tachycardia—nothing more. Trypanosomes were found in his lymph and blood, and he responded immediately to ordinary treatment. This case is of course still more striking than those described above, although details of the original infection were not available.

The evidence afforded by the host's subjective sensations in cases of this kind can of course only be obtained from man, and should be useful in studying trypanosome infections in resistant animals generally. All the volunteers were on full duty during the whole period of the development of their infections, and their repeated denial of any sign of discomfort was at first a very puzzling feature.

Strangeways (1935) has noted that in mice *T. gambiense*, after a brief period when trypanosomes are discernible in the peripheral blood, may remain latent in the region of the choroid plexus for many months without producing any apparent effect on the animal's well-being. Corson (a) has described a somewhat similar infection produced by a feebly pathogenic strain of *T. brucei* in a white rat. It is of course possible that some of the cryptic cases described above would if left alone have remained without obvious symptoms for months, during which time serious involvement of the central nervous system might take place.

In 4 of the 5 cases cited in the present paper the progress of the disease was obscured by later infections superimposed before a diagnosis had been made. On the other hand, in most of the protected volunteers infection, when it did ensue, speedily manifested itself. In the case of Z. F., the incubation period was 16 days and the onset typical.

Whether a cryptic infection develops or not will depend partly on the trypanosome and partly on the resistance of the individual. A virulent strain will doubtless soon declare itself; an avirulent may not. Typical virulent *T. rhodesiense* is unlikely to remain hidden for long; *T. gambiense* is often mild in man in many parts of Africa, and so is more likely to be overlooked. But this gap between the two organisms is lessened by the knowledge that *T. rhodesiense* is prone to lose its full virulence for man. Volunteer O. was infected by just such a strain.

The age, condition, and natural resistance of the individual will also play a part, and so will the frequency of exposure to reinfection; for it is highly probable that persons protected by Bayer 205 owe some and possibly a great deal of their immunity to the repeated inoculation and destruction of living trypanosomes within their tissues. This same process of repeated inoculation will take place in natives undergoing prophylaxis in an infected area; indeed, the more unhealthy the environment the greater presumably will be the immunisation of those protected.

There is good reason to believe that the resistance of both ruminants and man to trypanosomes depends to a considerable extent on the general well-being of the host. Years ago Roubaud (1921) drew attention to this factor in connexion with protozoal infections of man, and of late years it is becoming more and more widely recognised as of very great practical importance. Dumont (1935) has assembled the opinions of experienced observers in sleeping-sickness territories in the French African possessions, all of which emphasise the importance of the standard of living in determining the spread of the disease. At the Conference on Sleeping Sickness held at Entebbe in 1933 the improvement of the conditions of living among the native tribes in Eastern Africa was unanimously recommended as an essential part of any campaign against sleeping sickness. Any scheme of drug prophylaxis against infection should therefore be accompanied by a serious attempt to raise the standards of living of the exposed population, whose normal dietary is as a rule far from balanced according to modern ideas.

How these cryptic infections arise it is difficult to explain. They may be due to the trypanosome itself being in some way weakened by the drug (we have seen that this will not cover all such cases) or to the host's resistance being increased to a point where the trypanosome is restrained from exerting its normal action. The fact that most of the protected volunteers eventually developed ordinary symptoms shows that the virulence of the trypanosome undergoes no permanent change. On the other hand, the prolonged resistance shown by volunteer Z. F. can scarcely be due alone to the direct effects of the original 1.0 g. of Bayer 205 on each fresh consignment of metacyclic trypanosomes introduced at intervals over a period of some eleven months. His behaviour suggests rather that immunity is acquired from repeated "vaccinations" with living antigen, the immunisation beginning while the drug is still actively trypanocidal in the patient's tissues. Kligler and Weitzman (1926) found that repeated inoculation

of rabbits with dead trypanosomes induced hypersensitisation, whereas if the animals were inoculated with trypanosomes suspended in Bayer 205 definite resistance was produced. The same might occur in the protected subject during the first few weeks after the administration of the prophylactic.

It is almost certain that this obscure kind of infection will be overlooked in any ordinary examination of a native population for trypanosomiasis. For without gland enlargement or fever or malaise of some kind, and with a "negative" blood slide, there is little chance of a diagnosis being made. Cases of this nature could do much harm in spreading the disease.

APPLICATION OF BAYER 205

Does the prospect of cryptic cases constitute a vital objection to the use of Bayer 205 as a prophylactic? My own opinion is that it does not. Two seemingly good reasons are first that these cases are readily amenable to treatment, and secondly that they occur where no Bayer 205 has been used. The knowledge that they may occur will help, too, in their detection. When protection is needed for persons entering an infected area for some definite and limited undertaking, Bayer 205 should certainly be employed, the dose being repeated at intervals, say, of three months.

A more difficult problem is the protection of the indigenous population of a sleeping sickness area. I believe that here too Bayer 205, if employed under careful supervision and with the intelligent coöperation of the population itself, will be of great value. It should be borne in mind that *T. gambiense* is more likely to evade detection than *T. rhodesiense*.

Where the conditions in an infected area are such that the disease persists unchecked by clearing and other local control measures, then Bayer 205 should prove a valuable aid, if applied at regular intervals and to a population adequately supervised. To every inoculated individual protection will be conferred for two months at least, and in some for much longer. Of those whose period of protection is allowed to lapse, only a minority will develop cryptic infections; the majority, according to the experiments of this paper, will show the ordinary symptoms of the disease. Moreover, cryptic infections will be encountered apart from any system of prophylaxis.

There is little doubt that *T. gambiense* in many infected areas is spread by a comparatively small number of infective flies, any one of which may however be responsible for 30-40 cases during its life-time. Under these conditions the protection of the exposed population for a period of two or three months—during which time infected flies are dying out—will surely help enormously in checking the spread of the trypanosome.

In *T. rhodesiense* areas, where game animals can maintain for considerable periods strains pathogenic to man, this indirect effect of Bayer 205 will be less noticeable. But here also man is in the long run the main reservoir for human strains, and anything that reduces his susceptibility will be of ultimate value in controlling the disease.

To the medical man in Africa there is still something mysterious about the action of Bayer 205 and its curious potency against man's trypanosomes, and this may explain to some extent the rather vague fears entertained in certain quarters about its use as a prophylactic on a large scale. Dr. Van Hoof, however, informs me by letter that the results obtained with Bayer 205 and *T. gambiense* in the vast infected areas of the Belgian Congo suggest the

need for circumspection in the employment of the drug, and his figures will be awaited with great interest.

With increasing confidence, inspired by the knowledge that for three months at least the majority of those inoculated are safe, both the administrator and the native himself will find a way to that genuine coöperation which is so essential to success in this particular problem. Once freed from the dreaded old-time consequences of detection as a sufferer—removal to a distant hospital, wholesale evacuation of the homeland, and all the well-remembered restrictions and dislocations imposed in the days of our comparative ignorance and inexperience—the native will willingly come to the help of the authorities by searching out and reporting early cases of the disease, and coöperating to the full in any local measures that may be prescribed.

Conclusions

(1) A dose of 2.0 g. of Bayer 205 administered to an adult may be expected to confer protection against *T. gambiense* and *T. rhodesiense* for at least three months. The protection may last much longer.

(2) One volunteer (Z. F.) resisted infection by tsetse for 327 days after he had received 1.0 g. of Bayer 205.

(3) In a proportion of those protected by Bayer 205 and exposed to infection with human trypanosomes, infection when it does at length occur may be of a cryptic type, the patient showing no apparent symptoms for two months and possibly longer. An infection of this kind may gradually generate typical symptoms or it may become merged into a subsequent infection superimposed upon it and running a normal course. Cryptic infection can however arise independently in nature, apart altogether from the administration of any drug.

(4) A consideration of the behaviour of the volunteer Z. F. suggests that frequently repeated inoculations of living trypanosomes during the three or four months immediately following the administration of Bayer 205 lead to the establishment of a more prolonged immunity than that conferred by the drug alone without such frequent exposures to infection. If this is true, then the more intense the exposure in nature to infective tsetse the greater the benefit derived from the prophylactic.

Dr. W. H. Kauntze, director of medical services, Uganda Protectorate, has helped in a variety of ways by placing at my disposal his advice and the resources of his department. To Dr. J. Black and his colleague, Mr. Barkat Singh, of the Medical Department, Entebbe, I am indebted for continuous help throughout this research. All preliminary examinations and all treatment of the volunteers were carried out by these two officers. That no mishap of any kind has occurred is a tribute to their care and skill.

THE ANTAGONISM BETWEEN CURARINE AND PROSTIGMIN AND ITS RELATION TO THE MYASTHENIA PROBLEM

BY GRACE BRISCOE, M.B. Lond.

(From the Physiological Laboratory, London (R.F.H.)
School of Medicine for Women)

THE beneficial effect obtained in cases of myasthenia gravis by injection of prostigmin, reported by Dr. Mary Walker¹ and confirmed by other workers, has centred attention on the pharmacological mode of action of this drug, an analogue of eserine.* The reasons which led to this important observation were the resemblance between myasthenia and mild curare poisoning and the well-known antagonism between eserine and curare. Blake Pritchard^{2,3} has made advances by showing (1) that the form of the myogram in myasthenics differs markedly from the normal, showing quick fatigue with high rates of stimulation, and (2) that prostigmin restores the myogram to the normal form while simultaneously restoring the patient's strength.

The object of the present paper is to show that a parallel observation can be made experimentally. The myogram of the cat's quadriceps, showing quick fatigue under mild curarisation, can be restored to normal by a large dose of prostigmin such as would cause acute depression in fresh unpoisoned muscle. Some observations on the peripheral effects of (1) prostigmin alone, and (2) varying doses of curarine and prostigmin together will be given which suggest an explanation of this paradoxical effect. Details of technique have been given in other publications.⁴ The nerve-muscle preparation has been the quadriceps of the cat with circulation intact, and the movement of extension of the knee has been recorded. The cut nerve has been stimulated by neon lamp discharges which can be readily altered, both in strength and frequency.⁵

Control myograms are first taken, showing the responses to short spells (1-2 secs.) of different rates and strengths of stimuli. A small dose of curarine chloride is then injected intravenously. In a few minutes the contraction caused by the fast rate is not maintained as in the control but rapidly gives way. The myogram closely resembles that seen in myasthenics in response to fast rates. At this point a large dose of prostigmin (1 c.cm. for a 3-kilo. cat, preceded by atropine) is given intramuscularly. In a few minutes the myogram improves and returns to the normal (Fig. 1). Control experiments show that recovery due to gradual elimination of curarine would take an hour or more.

An indication of the mode of action of this antagonism is found by studying the peripheral actions of prostigmin and curarine separately in fresh unpoisoned muscle. The two factors in the myogram affected by these drugs are (1) height of contraction, (2) maintenance of the same.

THE ACTION OF PROSTIGMIN ALONE

Prostigmin in the large dose indicated produced marked and characteristic effect.

Five rates of stimulation (30, 50, 75, 105, and sec.) at submaximal and supramaximal strer

* Prostigmin was used in these experiments because it has been extensively employed clinically. Eserine has given experimental results. There is no reason to suppose that prostigmin has any particular advantage over the substance eserine.

FIG. 1.—Cat, 2.9 kg.; quadriceps. Time in seconds. Contraction is downwards in all tracings. Rate of stimulation, 150 per sec. Strength, just under maximal. (A) Control curve of normal muscle. (B) Same stimulus. Mild curarisation, 0.25 mg. per kg. intravenously. Tension not maintained. Arrow indicates cessation of stimulus. (C) Fourteen minutes after injection of 1 c.c.m. prostigmin intramuscularly preceded by atropine 2 mg. Tension maintained. Improvement in contraction was noticed four minutes after injection.

tested. Controls show that fast rates produce larger contractions than slow ones. Sometimes rates 105 and 150 per sec. produce contractions of equal size.

A few minutes after the intramuscular injection of prostigmin a progressive change is seen in both the size and shape of the myograms. The response to the fastest rate with strong stimuli is most affected, being both diminished in size and less well maintained, until eventually at the end of 10 to 20 minutes it is smaller than the response to the slowest rate and is twitch-like in character (Fig. 2). At the height of the depression, rate 75 per sec. usually produces the largest contraction and rate 150 the smallest.^{6, 7} This alteration in relative size of contraction is seen both with submaximal and supramaximal stimulation.

A third characteristic change is seen in prostigmin and eserine poisoning, but not with curarine. It is a modification of the initial curve of contraction which affects all responses. Normally the leg rises to full extension in one movement. After prostigmin with slow rate stimulation the movement is interrupted by a temporary falling back, after which the movement of extension is resumed. In cases of mild poisoning this jerk may not be more than an accentuation of the backswing which is often seen when a heavy limb is thrown suddenly into full extension by a supramaximal stimulus. In deep poisoning with fast rates of stimulation there is no recovery from this early depression and the response therefore becomes twitch-like. The myograms show that with all rates of stimuli the first movement of extension is alike, but the recovery from "inhibition" is swift in the slow rate responses. Extension therefore can still be maintained. These changes are more pronounced with a greater degree of poisoning. With weak submaximal stimuli similar changes may be seen, but the interruption occurs earlier in the curve of contraction (Fig. 3). During elimination of the drug the notch gradually disappears, until eventually the myograms show as smooth a curve as the controls. To sum up, there is in prostigmin poisoning a progressive deterioration affecting both the size and maintenance of contraction which is marked in the responses to the faster rates of maximal stimulation.

Signs of recovery from prostigmin poisoning appear within an hour of administration. Recovery is gradual and the effect of the drug is maintained for several hours. Recovery is complete when the fastest rate produces the largest contraction, which holds for a period of at least 15 minutes without loss of tension.

THE ACTION OF CURARINE ALONE

The peripheral action of non-paralytic doses of curare is well known. Bremer and Titeca⁸ have shown that contraction is not maintained whatever the rate of stimulation—i.e., 10 or 70 per sec. These observations have been confirmed.⁹

The point to be noted in responses to different rates after moderate doses of curarine (0.3 mg. per kilo) is that there is no fundamental change in the sizes of the contractions relative to each other. As in the control series the faster rates produce the larger contractions; that is, normal order is retained, though all the contractions are reduced in size and are twitch-like in character (Fig. 2 c). This is in direct contrast to the condition following prostigmin poisoning.

THE ANTAGONISM OF PROSTIGMIN TO CURARINE

If curarine be given in doses which cause temporary paralysis a large dose of prostigmin will halve (approximately) the time of recovery. For instance, a moderate dose of curarine produced in 12 minutes a paralysis which lasted for 4 minutes, after which small twitches reappeared. In 40 minutes recovery

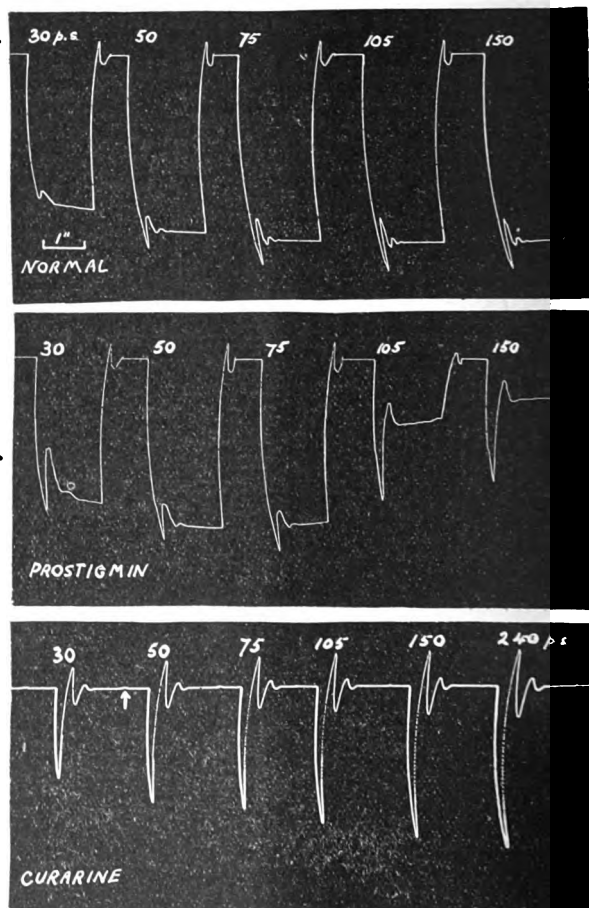

FIG. 2.—Quadriceps. All stimuli supramaximal (double just maximal strength). (A) Controls. Five responses to different rates of stimuli. Rate 30 per sec. produces smallest contraction and rates 105 and 150 the largest. Controls were also taken in reverse and random order. (B) Same stimuli, after prostigmin. Rate 75 produces largest contraction and rate 150 the smallest with rapid loss of tension. Response to rate 30 shows brief relaxation followed by recovery. (C) Another preparation. Twitch-like responses to all rates after curarine. Stimulation continued for at least one second. Arrow shows cessation of stimulus. Contractions larger with increases of rate.

FIG. 3.—Quadriceps. Submaximal stimulation. Control contractions showed smooth curves and increase of size with increase of rate. Time, one second. *Upper row*: Submaximal responses during recovery from deep prostigmin poisoning, injection 25 minutes earlier. Slower rates produce larger contractions. Well-marked notch in all tracings and coarse tremor. *Lower row*: Same stimuli. Ten minutes later, notch less well marked. Slowest rate produces smallest contraction. Two hours after injection curves were as smooth as in controls and rates 30 and 50 gave smaller contractions than the three faster rates. Supramaximal fast rate responses still showed some depression.

was still incomplete—i.e., a slow rate of 30 per sec. could just maintain a contraction for 5 seconds without sign of failure. At this point a second similar dose of curarine was given which caused paralysis in 1 minute. Atropine and prostigmin were now injected and a similar stage of recovery was reached in 23 minutes—i.e., a stimulus of slow rate maintained a contraction for 5 seconds.

It has already been shown (Fig. 1) that the quick fatigue produced by mild curarisation can be restored to normal by an injection of prostigmin. It is remarkable that this antidotal action which restores responses to all five rates is secured by giving poisonous doses of prostigmin such as would cause, in normal muscle, the marked depressant effects illustrated in Fig. 2B. There may be no sign of characteristic prostigmin depression. Contractions have been recorded, showing normal curves, for a period of over four hours after injection of the drug. When the initial dose of curarine was smaller, slight signs of prostigmin effect could be detected about an hour after injection of the antidotal large dose in that response to rate 150 was smaller than response to rate 105.

ANTAGONISM OF CURARINE TO PROSTIGMIN

When an animal deeply affected by prostigmin receives a dose of curarine (0.3 mg. per kilo) capable

FIG. 4.—Quadriceps. Stimuli supramaximal in strength. (A) Normal responses to rates, 30 and 150 per sec. 12.8 P.M. Prostigmin, 1 c.cm. (B) 12.39 P.M. Slow rate response shows temporary relaxation and recovery. Fast rate response is twitch-like and smaller. 12.40 P.M. Curarine, 0.3 mg. per kg. (C) 12.41 P.M. Both responses nearly normal.

of producing in the normal animal twitch-like responses to all rates a striking antagonistic effect is seen. The small twitch-like responses to the fast rate (150 per sec.) are suddenly improved, they show less depression and become larger than responses produced by the slow rate stimuli (30 per sec.). This result occurs in less than a minute (Figs. 4 and 5).

If the doses are fortunately balanced there may be an almost complete restoration to the normal and the notch disappears from submaximal contractions. Usually the restoration is incomplete and does not last long. In a few minutes the characteristic curarine effect becomes predominant. All the myograms show depression but normal grading is resumed in that the faster rates produce larger contractions. The presence of prostigmin, however, diminishes the degree of depression produced by the curarine.

If a smaller dose of curarine (0.15 mg. per kilo) be given, the antagonistic effect may show itself only

FIG. 5.—Records taken on slow rate of drum. Two-second spells of supramaximal stimuli every ten seconds. Rate raised between each spell (30, 50, 75, 105, 150 per sec.). All taken in same sequence. (A) Before prostigmin. Rate 30, smallest contraction. (B) After prostigmin. Rate 150, smallest contraction and twitch-like. (C) Two minutes after intravenous injection of curarine, 0.3 mg. per kg. Curves nearly restored to normal. Little curarine effect developed, so 0.3 mg. per kg. curarine was given one and a half hours later. (D) Eight minutes after second dose. Typical curarine effect. All contractions are twitch-like and faster rates give larger contractions.

by reducing the time of recovery from prostigmin poisoning from several hours to one hour—i.e., there is a complete absence of curarine depression.

Discussion

The work of Loewi, Dale, and many others has brought great support to the theory of a chemical transmitter of excitation between nerve-ending and effector organ.¹⁰ It is known that eserine delays the normal swift destruction of this transmitter by the esterase in the blood, thus causing accumulations. The present experiments indicate that such accumulations are capable of causing depressant effects in normal muscle contractions. Can the paradoxical effect of prostigmin—depressing function in unpoisoned muscle restoring function in curarised muscle—be explained on this theory?

Two different solutions can be offered. The first supposes that the fault in curarine poisoning and in myasthenia gravis lies in the too rapid destruction (or insufficient production) of transmitter. This fault in both cases would be rectified by the delaying action of prostigmin on the destruction of the transmitter and normal contractions would follow. Conversely, in muscle poisoned by prostigmin the delay in destruction of transmitter would be counterbalanced by the

speeding-up action of curarine. The second explanation, suggested to me by Sir Henry Dale, is that curarine counteracts the depressant effects of prostigmin not by affecting the output or stability of the transmitter but by raising the threshold for its depressant action when excess is present. On the other hand, if curarine raises the threshold for stimulation, prostigmin would counteract the depressant effect of curarine by increasing the amount of transmitter which would enable the obstacle of raised threshold to be overcome. An observation has been made by Dale and his associates which is in favour of the latter suggestion. They have shown that there is no obvious fall in the amount of transmitter, identified by them as acetylcholine, in the venous effluent of an eserinated muscle whose contraction has been blocked by curarine. It is not possible at present to decide between the alternative theories.

That the depressant effects in prostigmin and curarine poisoning respectively are not identical in origin is suggested by a comparison of the myograms resulting from different rates of stimulation. Although twitch-like responses are obtained with both drugs in myograms from the fast rate, a marked difference occurs with the slower rates. Under curarine each contraction, whether with slow or fast stimulation, starts normally and then fails at once. With deficiency of transmitter or rise of threshold there is no reason why the relative sizes of the contractions should be disturbed. Under prostigmin the fast rates produce contractions which are deficient in size and power of maintenance, but the slow rate myograms are less affected. It is difficult to explain this result unless it be accepted that excess of transmitter can "blanket" contractions when high rates and strong stimuli are accentuating such excess. The notching in the initial curve of contraction is also difficult to explain. It may be due to a kind of "adaptation" to excess of transmitter, which in the fast rate myograms does not have time to show itself.

It is clear from these experimental findings that some balance, in relation either to the rate of destruction or to the threshold, has to be preserved if the nerve-muscle unit is to function efficiently. This balance can be readily upset or restored by either of the drugs studied. Recent work by Cowan¹¹ indicates that neither nerve trunk nor muscle-fibre is affected by prostigmin, so that by exclusion the site of its action must be the neuromuscular junction. This has long been recognised in the case of curare.

To apply these results to the problem of myasthenia: if this condition is really akin to curare poisoning either of the two solutions offered would explain the temporary alleviation procured by prostigmin. Stedman¹² has estimated the choline esterase of blood in (a) myasthenics, (b) normals. He found no excess of esterase in the first group. If it be accepted that the esterase content of the blood is a measure of its concentration in the tissues this piece of evidence is against the theory that the condition of myasthenia gravis is due to the excessive destruction of acetylcholine by the enzyme in the blood.

Summary

The peripheral actions of prostigmin and curarine have been studied separately showing that either is capable of producing acute depressant effects, which, however, are not identical. Their mutual antagonism is such that normal muscular action can be preserved when poisonous doses of the drugs are exhibited together. These results can be explained on the

theory of chemical transmission of excitation. Their application to the myasthenia problem is discussed.

RÔLE OF ULTRA-VIOLET RAYS IN THE DEVELOPMENT OF CANCER PROVOKED BY THE SUN

By Prof. A. H. ROFFO

DIRECTOR OF THE INSTITUTE OF EXPERIMENTAL MEDICINE AND CANCER RESEARCH, BUENOS AIRES

IN 1932, in a paper¹ on the part played by the sun's rays in the causation of skin epitheliomata, I pointed out that though this suggested aetiology has produced some very interesting communications, none of their authors (Dubreuilh, Gougerot, Larabi, &c.) has adequately explained the process by which the transformation to malignancy takes place.

My own first observations on this process were published in 1928,² when I drew attention to the high incidence in the Argentine Republic of cutaneous epitheliomata, localised exclusively on the face and on the back of the hands. Among 5000 cancer patients attending the Cancer Institute of Buenos Aires none showed cancer of any part of the skin covered by clothing (except in two or three cases where tumours developed on naevi or burn scars). The predilection of cutaneous cancer for regions exposed to the sun is shown by the following rates obtained at the Institute:—

EPITHELIOMA OF SKIN (1500 CASES)

(a) Regions exposed to the sun.		%	(b) Regions protected by clothing.		%
Skin, face	..	95.51	Hairy skin	..	1.02
Skin, back part of the hands	..	3.07	Foot	..	0.52

In the face the parts most often affected are those most prominent and exposed; for example, the nose bears 61 per cent. of the facial epitheliomata, compared with 18 per cent. on the cheek and hardly any on the forehead. It is also found that men are more receptive (70.9 per cent.) than women (29.1 per cent.), the lower incidence in women being related to the care they take of their skin, protecting it with powder. The few epitheliomata seen in females have been only in countrywomen and those of very humble standing who do not bother to protect their skin. The lesions develop both in workmen and in those of the higher social classes who have to expose themselves to the sun all day—e.g., farmers and planters. Sufferers from epithelioma are generally found to have very white (photosensitive) skins, and I have not seen a single case in natives, negroes or mulattoes. The patients have a peculiar aspect: the face up to the brim of the hat, and the hands up to the sleeves of the coat or shirt, present at first a diffuse erythema, and later numerous pigmented zones, which contrast with the white skin of the forehead and the forearm. These pigmented zones get more pronounced and hyperkeratotic; then they ulcerate

and become cancerous. These changes are associated with hypercholesterol of the tissues exposed to the sun, known as "cholesterol mask" and "cholesterol gloves."

The hyperkeratosis which leads on to the epithelioma is dominated by a photodynamic mechanism, and for fulfilment of the process the following factors are necessary: the living cell, a sensitising photodynamic substance, the presence of oxygen, and the rays of the sun. Consequently I ascribe great importance to a substance, cholesterol, which is always present in the living protoplasm, and plays an active part in cell development. Experiment has shown that it is present in excess in cancerous tissues, that it is heliotropic, and that it has photo-activity.³ Moreover we find that the parts of the face most exposed to the sun (nose) which develop the highest percentage of epitheliomata have also the highest content of cholesterol. This is seen from the following percentages based on 302 cases of facial skin cancer examined at the Institute:—

Incidence of epithelioma.		Cholesterol content of dried skin.	
	%		%
Nose	61.40	Nose	0.74
Cheek	18.00	Cheek	0.50
(Abdomen) ..	0.06	(Abdomen) ..	0.20

As a result of these observations, experiments have been undertaken which confirm the view I have outlined. In white rats I have obtained tumours of different histopathogenesis (epitheliomas and spindle-cell sarcomas) in unprotected parts of the skin (ears and ocular conjunctiva). These tumours have developed under the influence of the total sun rays or under ultra-violet rays with a wave-length of 1800-3400 Å. In animals, as in human beings, the skin is found to have an abnormally high cholesterol content before the development of the tumours. A summary of the experiments made on a series of 10 rats, with ultra-violet rays from a Hanau apparatus, is given below.

Three of the rats died from insolation, the experiments having been carried out in summer. When the temperature was very high, a ventilator was placed over the animals.

The period of exposure was gradually increased, the doses of ultra-violet rays being equal to the average of the sun units, measured with the dosimeter S.V. At first irradiation lasted 5 minutes; it was then increased and after fourteen days it had reached 1200 minutes daily. The longest test lasted nine months and five days. The rats were fed in the same way as the non-irradiated control animals, none of which developed cancer.

FIG. 1 (Rat 1).—Spindle-cell sarcoma of the conjunctiva of the eye, partly covered by Malpighian conjunctival epithelium.

The following Table summarises the results obtained.

Results of Ultra-violet Irradiation of Rats

Rat No.	Duration of the process in months and days.	Lesions provoked.
1	8 m. 13 d.	Enormous sarcoma of eye. Multiple lesions, papillomatosis, and hyperkeratosis of the ears.
2	8 m. 28 d.	Large cancrioid of left ear. Multiple lesions, papillomatosis, and hyperkeratosis. Spindle-cell sarcoma of right ear.
3	8 m. 20 d.	Enormous spindle-cell sarcoma of neck, previously shaved. Multiple hyperkeratotic lesions; papillomatosis of the ears. Voluminous cancrioid of left ear.
4	8 m. 12 d.	Large tumour of eye (spindle-cell sarcoma). Multiple formations on ears; hyperkeratosis, papillomatosis, and epitheliomata.
5	7 m. 6 d.	Large tumour of eye (spindle-cell sarcoma). Multiple formations on ears; hyperkeratosis and papillomatosis.
6	9 m.	
7	9 m. 5 d.	Enormous epithelioma formed on ear; multiple hyperkeratotic lesions and papillomatosis.

In looking for records of similar experiments I have found two papers by Findlay⁴ who has induced papillomata and epitheliomata in mice by exposing them to ultra-violet rays. But these animals had been artificially depilated with sodium sulphide. In a third paper Putschar and Holtz⁵ report having obtained epitheliomata of the ear, but they do not mention spindle-cell sarcoma.

The second part of my experiments was intended to elucidate the process by which the rays cause the cells to become cancerous. I regard this process as a vital phenomenon which can only take place in the presence of certain sensitising substances, which are activated by the sun's rays. My observations⁶ on cholesterol show it is increased in amount in the skin of

FIG. 2 (Rat 3).—Ear tumour. Highly anaplastic pavement carcinoma reaching down to the cartilage.

animals irradiated in certain regions, and they have been confirmed by Kawaguchi.⁷

In naturally hairless regions (ears) I have been able to demonstrate any excess of cholesterol in the skin before any of the histological changes of cancer could be detected. The increase in cholesterol of the irradiated ear in relation to the non-irradiated ear reaches a very high figure (1.5 g. %).

SUMMARY

It is clear that the rays of the sun and of the actinic spectrum will produce malignant tumours without the intervention of other agents. In rats the tumours are of epithelial type—epitheliomata with conspicuous anaplasia, and large sarcomata of the spindle-cell type—and they attain their largest size after seven to nine months. They grow in the regions naturally free from hair (ears and conjunctiva) or artificially depilated. The process begins with hyperplasia, hyperkeratosis, papillomatosis. The action of the rays is not specific for particular kinds of cells, for the epithelial cells and the conjunctiva respond in the same manner to the rays. The proportion of animals developing tumours is very high (all of 7 surviving rats), and in the same animal both sarcoma and epithelioma may be observed. The irradiation produces a local excess of cholesterol which can be detected before there are any histological changes. In view of the heliotropism and photo-activity of cholesterol I look upon its increase as highly significant.

ADDENDUM

Since this paper was written I have made further observations and I would like to add the following conclusions.

Exposure to the sun's rays is in itself sufficient to produce malignant tumours in 70 per cent. of rats and mice. The process takes 7-10 months passing through hyperplasia and papillomatosis, and the carcinomatous and sarcomatous animals alike die in a state of cachexia with metastases in lymph-glands. In the development of cancer in this way cholesterol plays an important part as a photo-active, heliotropic, and energising substance. Experiments performed with different sorts of rays (total sun, filtered sun, ultraviolet rays, luminous rays, neon gas, and short Hertzian waves) show that the power of the rays to produce tumours depends on their actinic and not on their luminous intensity. Histologically the lesions obtained closely resemble those observed in persons with photosensitive skins which have been much exposed to the sun, and these observations emphasise the danger of such exposure.

ROYAL DEVON AND EXETER HOSPITAL.—There is a loss at this hospital of over £4000 on the year's working and the financial position is less satisfactory than for many years past. The cost of road accidents is large, while various internal improvements and a greater number of patients have also increased expenses. About 30 beds will shortly be added and it is essential that the number of annual subscribers should also grow.

GONADOTROPIC HORMONES IN THE TREATMENT OF STERILITY IN MAN

BY V. E. LLOYD, M.B. Lond.

DIRECTOR OF THE VENEREAL DISEASES DEPARTMENT,
GUY'S HOSPITAL, LONDON

It seems to have been clearly established that the normal descent of the testes into the scrotum is closely associated with the action of gonadotropic hormones. The recent clinical trial of such hormones in the treatment of delayed descent of the testes in man has resulted in an encouraging proportion of successes. The initiation and degree of spermatogenesis in animals also appears to be under hormonal control. Excision of the anterior lobe of the pituitary gland is known to be followed by cessation of spermatogenesis as well as atrophy of the accessory reproductive glands, and the return of spermatogenesis after implantation of anterior pituitary tissue has also been reported.

Schockhaert¹ has successfully used gonadotropic hormones to induce precocious spermatogenesis in birds, but the many attempts to influence the immature mammalian testis in the same way have given uncertain results, and clinical improvement following the administration of these hormones in the treatment of azoospermia or oligospermia in man has rarely been described. Brosius and Schaffer² record one case of azoospermia following mumps orchitis in which therapy with urinary gonadotropic hormones was followed by the production of motile spermatozoa; Brosius³ has also reported pregnancy after the use of these hormones in one case of deficient spermatogenesis in man. There are so few reports of this kind, however, that the following cases are likely to be of interest.

CASE 1.—Man aged 27. Married three years without children; no contraceptives had been used. On examination in November, 1932, his general condition was good, and his secondary sex characters normal except for lack of full development of adult male voice. He had suffered from mumps after puberty, but there had been no known orchitis. Both testes were smaller and softer than normal; the epididymes were thin and flaccid; the prostate gland was small; and the seminal vesicles could not be palpated. After detailed inquiry, sexual desire, potency, ejaculation, and orgasm were considered to be normal. The patient's wife had been seen by Mr. Frank Cook who had found no evidence of any disease or abnormality of the pelvic viscera.

A first specimen of semen was examined in December, 1932, 23 hours after coitus; the volume was 3.5 c.cm. and it contained 2 million spermatozoa per c.cm., none being motile. Films stained with iron hæmatoxylin and eosin showed 24 per cent. of abnormal spermatozoa. As only two days had elapsed since the previous coitus a further specimen, obtained after a longer interval, was examined in February, 1933. This specimen, which showed no motility 12 hours after production, contained 14 million spermatozoa per c.cm. Advice was given as regards sexual rest, open-air exercise, and increase of the protein and vitamin content of the diet. A third examination of the semen in May, 1933, gave a spermatozoa count of 22 millions per c.cm. and showed about 50 per cent. motile spermatozoa 14 hours after production.

Following this response a course of injections of a urinary gonadotropic hormone (Parke Davis and Co.'s Antuitrin S) was given at approximately weekly intervals, in doses equivalent to 100 rat units, for a period of four months. The last of these injections was given in December, 1933, and pregnancy of the wife was diagnosed in March, 1934. A final examination of the semen a few weeks later showed a high degree of motility 11 hours after production and the maintenance of motility of some spermatozoa up to

22 hours. The spermatozoa content of this specimen, which was 6 c.cm. in volume, was 69 million per c.cm. A differential count revealed abnormality of 8 per cent. A normal full-term child was born in October, 1934.

The main features of this case are set out in Table I.:

TABLE I.—*Examinations of Semen in Case 1*

Date.	Volume (c.cm.).	Hours before exam.	Motile spermatozoa.	Total sperm. (mill. per c.cm.).	Abnormal sperm. (per cent.).

TREATMENT DIRECTED TO EXERCISE AND DIET					
May, 1933	4	14	About 50%	22.5	17.5
TREATMENT WITH ANTUITRIN S. SEPT.—DEC., 1933					
Apr., 1934	6	11	About 50%	69	8

CASE 2.—Aged 27. Married five years and childless; no contraceptives had been used. When aged 24 the patient had suffered from an attack of mumps with right-sided orchitis. There was no history of any venereal disease. Two years previously he had had medical treatment for a suspected duodenal ulcer. His wife had recently been examined by Mr. Cook and considered free from any pelvic visceral disease or abnormality. On examination in March, 1933, the general condition was good and the secondary sex characters well marked. The penis, urethral meatus, and left testis were normal, but the right testis was of small size, though its sensitivity was normal. Both epididymes were apparently empty and almost impalpable; the prostate gland was abnormally small; and both seminal vesicles were only partly distended.

The first specimen of semen examined in May, 1933, was 2 c.cm. in volume, and less than a dozen feebly motile spermatozoa were seen three hours after its production. The spermatozoa count was 7 million per c.cm., and a differential count of stained films showed 17 per cent. of abnormal spermatozoa. Bi-weekly injections equivalent to 100 rat units of antuitrin S were given during June and July, 1933. Sexual rest and an increase in vitamin-rich foods were advised. At the second examination of semen in November, 1933, the volume was 1.5 c.cm. and only six feebly motile spermatozoa were noted three hours after production. The spermatozoa count, however, had risen to 52 million per c.cm., and the proportion

TABLE II.—*Examination of Semen in Case 2*

Date.	Volume (c.cm.).	Hours before exam.	Motile sperm.	Total sperm. (mill. per c.cm.).	Abnormal sperm. (per cent.).
May, 1933	2	3	Less than 12	7	17.2
ANTUITRIN S DURING JUNE AND JULY					
Nov., 1933	1.5	3	6 (feebly)	52	12.5
ANTUITRIN S DURING NOVEMBER AND DECEMBER					
May, 1934	3.5	5	About 10% (highly active)	75.5	10.5

abnormal was reduced to 12.5 per cent. A further series of injections of antuitrin S was given once weekly during November and December, 1933. A third examination of semen followed in May, 1934, when the volume was found to be 3.5 c.cm. There were about 8 per cent. of motile spermatozoa, some highly active, five hours after coitus, and the spermatozoa count was now 75.5 million, with 10.5 per cent. abnormal. In view of the increase in the numbers of spermatozoa no further treatment was given. Pregnancy in the patient's wife was diagnosed in April, 1935, and a healthy child, 10 lb. in weight, was born last November.

Table II. summarises the various counts made.

In both these cases the number of spermatozoa increased and their quality improved after administration of gonadotropic hormones. In both of them, moreover, the treatment was followed by pregnancy of the wife leading to birth of a normal full-term child, although the marriages had previously been sterile for periods of three and five years.

THREE ARTERIAL EMBOLECTOMIES IN THE SAME PATIENT

INCLUDING ONE IN EACH FEMORAL ARTERY

By H. I. DEITCH, M.S. Lond., F.R.C.S. Eng.

RESIDENT SURGICAL OFFICER, BRADFORD ROYAL INFIRMARY

ONLY ten cases of successful arterial embolectomy have been recorded in Great Britain. The case here reported is the first, so far as I know, in this country of successful femoral embolectomy, and it is singular in that in this man embolectomy has now been successfully performed upon both his femoral arteries at an interval of a year. He has had altogether three separate emboli removed from three different sites—one in January, 1934, and two others in December, 1935. The patient illustrates the after-history of embolectomies as described in a recent leading article in *THE LANCET*,¹ and shows that the prognosis of successful embolectomy is that of the primary condition, and is not, or should not be, affected by the operation itself.

FIRST ILLNESS

The patient was a man, aged 44, suffering from auricular fibrillation and bedridden on and off for 18 months. He was admitted to hospital Jan. 4th, 1934, with a history that a week previously he had had an attack of agonising colicky pain across the lower part of the abdomen, so severe that in spite of being bedridden, he had to get up and walk about to relieve the pain. His bowels moved, but he passed no blood. At the time, and subsequently until his second operation, I assumed that this pain was due to a small mesenteric embolus. I am now convinced however that this pain was spasm in the large vessels on the posterior abdominal wall, due to the passage of the embolus. At 9.45 p.m. on the day of admission there was a sudden feeling of numbness in the left knee. This was painless at first and gradually spread down his leg to the foot. The limb felt cold and dead and when he touched it with his other foot it felt "as though it belonged to someone else." Within 15 minutes the numbness changed to a tearing, burning pain; the limb felt as if it were bursting, as though the skin was too tight, and the pain began to spread up the thigh. It was, he said, worse than anything he had suffered in his life, and it persisted unchanged until operation. He applied compresses of scalding water to the leg, but these failed to relieve the pain, and it was only slightly alleviated by morphia gr. $\frac{1}{4}$. Dr. L. L. Hurwich saw him and diagnosed the condition immediately as one of embolus of the femoral artery and sent him to hospital, where he was admitted at 12.30 a.m. on Jan. 5th.

Examination.—I saw him at 1.30 a.m.; he was still in a condition of extreme shock, pallid and sweating, with drawn face and suffering intense pain in spite of the morphia. His left lower limb below the middle of the thigh was cold, shrunken, marbled, and felt greasy to the touch. It was anæsthetic and voluntary movements were absent. Pulsation could only be felt in the upper few

¹ *THE LANCET*, Jan. 4th, 1936, p. 33.

inches of the common femoral artery—i.e., in the region where one feels it in the normal thigh—but not in the vessels about the ankle.

The operation was begun at 2.30 A.M., and as the pain had commenced above the knee his popliteal artery was first explored under local anaesthesia, together with morphia, hyoscine, and atropine. The artery was readily exposed and found to be collapsed; it was obvious that the block was higher up. The femoral artery was therefore next explored in Scarpa's triangle, the pulsation being traced down to where it ceased, which was just above the origin of the deep femoral artery. The upper margin of the embolus could be felt as a sharp edge; its lower limit passed imperceptibly into a long clot which extended several inches down the superficial femoral artery. The affected length of the artery was isolated only on its superficial aspect, and fine rubber tubes were passed under the vessel above and below the affected segment; it was occluded by pulling upon the rubber tubing, thus kinking it and complete occlusion was obtained by pressing the two parts of the rubber tubing together close to the artery. The vessel below the clot was gripped between the finger and thumb of the left hand, and a longitudinal incision was made over the embolus. As the artery was opened the embolus, followed by the clot, was milked out in one piece by the finger and thumb from below, passing upwards along the vessel. Extrusion was accompanied by a gush of blood which, from its direction, must have come from the deep femoral artery. The milking process was repeated, and a probe was passed down the vessel; the incision was then sutured. When this was completed pulsation had returned to the exposed length of the superficial femoral artery and the patient declared that his pain had all gone; his general condition also began to improve immediately. By the time the wound was closed capillary reaction had returned to the foot and sensation was also coming back. Pulsation did not return to the posterior tibial artery until that evening.

The wound healed by first intention, and the man was discharged home in about two weeks. In May his doctor informed me that he was in good health and that his leg had remained normal in all respects.

During the operation several interesting facts were noted; that, in the region affected the induction of anaesthesia was unnecessary, as only above the level of the embolus in the artery was sensation present in the artery itself; the tissues in the affected area were bloodless; the superficial tissues appeared to be insensitive to the ordinary operative manoeuvres up to the same level, and this level appeared to coincide in the limb very accurately with the level of the embolus in the artery. It was difficult to secure haemostasis and to appose accurately the edges of the incision at the site of the embolus, although it was easy above that level; haemostasis at the suture line was readily obtained in the uninvolved portion of the artery, but was delayed in the affected part, probably attendant upon the restoration of the circulation in the walls of the artery. After suturing the vessel the upper part of the incision was dry immediately. The lower part required swab pressure for several minutes before it, too, became dry.

SECOND ILLNESS

On Dec. 14th the patient was readmitted to the hospital as an emergency with a history of having had the previous day an attack of abdominal pain, vomiting, and diarrhoea; there was no blood in the motions. The pain commenced to the right of the umbilicus and stayed there for about an hour and then moved down to the right iliac fossa and also to the right loin. Later the pain became worse and also radiated down to the right testis; he vomited every time he drank and he could not sleep because of the pain. He had no increased frequency or haematuria, and he was sent into hospital as a case with possibly renal colic, or, from his history, an embolus of the renal artery.

On admission there were no physical signs obtainable, and it was decided to watch him. His urine was normal

in all respects, and it was thought most probable that he had an embolus. Between Dec. 15th and the morning of the 18th he was quite well without any pain or other symptoms. At 10.20 A.M. on the 18th he suddenly complained that he was getting pain in the middle of the thigh and his right leg was going dead "just as it had done last time." At 10.30 A.M. when I saw him the right leg was exactly as the left had been one year previously, and the diagnosis of an embolus at the origin of the right deep femoral artery was made. While waiting to be taken to the theatre he complained that his left leg was also feeling numb, and that he had colicky pain across the lower half of his abdomen. On re-examination pulsation was still present in the right common femoral, but had disappeared from the left. It was therefore thought that in addition to the embolus in his right femoral artery he had an embolus at the bifurcation of the left common iliac artery.

Operation was begun at 11.30 A.M., by which time both lower limbs were cold, pallid, and anaesthetic. He still had no great degree of pain, his complaint being only of the numbness. Spinal anaesthesia was used, and an oblique incision was made cutting through muscle to expose extraperitoneally the left common and external iliac arteries, the peritoneum being retracted well to the right side. A large embolus was felt in the common iliac artery proximal to its bifurcation. The common iliac, just below its origin, and the external iliac, well below the embolus, were occluded by rubber tubing, and the artery was incised just above the clot. Owing to the depth and the difficulties of exposure, it was impossible to incise the artery, as one wished, completely above the embolus. By incising the artery, however, and by milking up the embolus I succeeded in removing it intact; its exit was accompanied by a spout of blood which appeared to come from the internal iliac. The wall was sutured and with swab pressure for a few moments became quite dry. After waiting a few minutes pulsation could be felt in the external iliac artery, and even before the wound was closed, colour had returned to the foot. The right common femoral was exposed and an embolus was removed in a way similar to that on the left a year previously. Here, however, one was able to incise the vessel completely above the embolus, and haemostasis was immediate and complete on suturing the incision. By the time this incision was sutured, pulsation had returned to both the posterior tibial and dorsalis pedis arteries of the right foot.

Progress.—Healing of the incisions was uneventful, and both legs became normal with the single abnormality, that even after two weeks, when he was sent home, pulsation had not returned to any vessel in the left lower limb, in spite of this the superficial circulation, feeling and movements were quite normal. This is difficult to explain as pulsation was seen and felt to return to the external iliac at the operation. The vessel appeared in a state of spasm when incised; suturing was difficult and possibly the bites taken of the wall were too large. This, in association with the previous embolictomy in the left common femoral, might account for the persistent absence of pulsation.

COMMENT

In all three vessels operated upon there was much spasm in the affected portions, and it appeared to diminish the size of the artery by more than a half. In the first operation an ordinary curved intestinal needle was used to suture the artery; in the second, a very small hare-lip needle, which is much more suitable to use; but the former, in spite of its size, was quite satisfactory. Ordinary fine silk soaked in liquid paraffin for half an hour was used on both occasions.

Recently attention has been drawn to non-operative methods of treating the condition of arterial embolism, but the operation is so simple and easily performed, and can be carried out in the limbs under local, or possibly no other anaesthetic than morphia, &c., that I think no alternative is required. When once it has been seen, one does not readily forget the

dramatic relief which is given to a patient by removing an embolus, and by the immediate improvement in his condition. It seems important to relieve the obstruction at a point where not only the main but the collateral circulation to a part is simultaneously occluded. Even if some clot remains behind, one is sure of freeing at least the collateral circulation, and this, even if it does not prevent gangrene, limits it to the more distal parts of the limb. In this patient, when an embolus was removed from the junction of the superficial and deep femoral arteries, a very strong gush of blood came from the deep femoral, so that we felt sure that even if only the passage between the common and deep femoral were freed, a good circulation would be established.

In all three operations there was no doubt that the embolus, from its size, could not have gone further; there was so much spasm below and, to some extent, above, that the embolus stood out as a definite bulge in the line of the artery. Hence massage in these instances, where it could have been applied, would have been valueless. In the first operation, when about five hours had elapsed between onset and operation, a clot about 3 in. long was present distal to the embolus. In the second and third operations, when only an hour had elapsed, there was no clot present at all. This is why success follows an early operation more often than one long delayed. All three emboli were tough, solid masses.

In the history of this case there were several features which are not typical. The site of maximum pain was well below that of the embolus, and not, as is usually described, directly over the site of impaction, and the onset which was gradual rather than sudden. In his second attack he had no severe pain even after an hour. From the history preceding this attack I feel sure that his abdominal pain on both occasions was due to spasm and to the passage of the embolus along the aorta.

I wish to record my gratitude to Mr. Peter McEwan for his kindness in allowing me to treat this case and to report it to the Bradford Medico-Chirurgical Society in January, 1935, and also for his permission to publish it.

A CASE OF ALCOHOLIC PSEUDO-PARESIS

BY E. W. ANDERSON, M.D. Edin.,

M.R.C.P. Lond., D.P.M.

MEDICAL DIRECTOR OF THE CASSEL HOSPITAL FOR FUNCTIONAL NERVOUS DISORDERS, PENSHURST, KENT

THE condition known as alcoholic pseudo-paresis was more familiar to the older psychiatry than it is to that of the present day, and cases are now comparatively rare. Bleuler writes: "Probably because the concept of paresis has become clearer we have not seen for ten years any disease we could designate as alcoholic pseudo-paresis."¹ As there is even a tendency to deny its existence altogether I think it desirable to place on record the present case, which is the first in my experience.

The condition was first described as a clinical entity by Magnus Huss² in 1852, but it was recognised imperfectly before that time. For example Huss quotes Brühl-Cramer's account of "a condition of torpidity of the nervous system associated with the appearances of general muscular weakness and thus a particular sluggishness of all functions voluntary as well as involuntary." Since Huss wrote, there have been many other reports of cases, including a

very interesting one recorded by Régis³ in 1883 where the patient had had no fewer than 16 attacks of the disorder, in some of which it was diagnosed as general paralysis by distinguished psychiatrists and in all of which it cleared up completely. Good descriptions of the disorder are to be found in all text-books of psychiatry and it is unnecessary to go into particulars here. Like the Korsakow syndrome, of which it is a form, it appears to be rather commoner in women. All writers stress the good prognosis if alcohol be withheld.

Mrs. A. B., aged 52, was admitted to the Cassel Hospital on July 26th, 1935. This hospital does not admit organic cases but from the account given by her doctor it seemed that she might benefit from admission.

The family history was essentially negative, but her husband was unable to furnish many details of it or of her early life.

Personal history.—The patient, who had been on the stage, was of Scottish birth and extraction and had evidently been a difficult child. There was a definite history of syphilis, which had been fully treated by a distinguished syphilologist who pronounced her free of the disease before marriage; the blood Wassermann reaction had been negative 15 to 20 years before admission. There was also a history of "a dropsical tendency" about 30 years previously—perhaps a syphilitic nephritis. More recently she had been operated on for arthritis of the knee, but no further details of this were forthcoming.

The patient had had a child before marriage but no other children. She was married in 1908 and her menopause occurred about 1½ to 2 years before admission to hospital in 1935. Her married life had been extremely unhappy, both because of her husband's taste for other women and her own cyclothymic, paranoid personality, quick to see insults and hypersensitive, jealous, and exacting. In addition she was prone to violence, assaulting servants if they displeased her and flying into uncontrollable rages. All this had been observed before she started drinking; for she had become a teetotaler from marriage and there was a history of only a year's indulgence in gin and burgundy up to admission. There was no history of drugs.

Before her menopause there had been no signs of definite mental illness; but about this time she became very depressed and apathetic, although she had hitherto been an active woman with many interests. Finally she made a suicidal attempt which her husband thought was chiefly histrionic but which led to her commitment. After a few weeks in a mental hospital she was discharged recovered and to her husband seemed perfectly normal. Soon afterwards however the old quarrels began anew and life with her at home was impossible. For a year she had been drinking heavily. It is hard to say with precision when the symptoms which she presented on admission began, for her husband was not living with her at the time. That they were of recent origin is almost certain—at least in their grosser form—as her private doctor could scarcely have overlooked them. It is likely that he did not see her immediately before admission. There was no history of any other alcoholic psychosis.

On examination a well-built, rather stout woman of florid complexion. On reaching hospital she was unable to walk and could hardly stand without assistance. Her pupils were equal, circular, and moderately dilated. The right reacted very sluggishly to light (direct) but the consensual response was brisker. The left pupil was also sluggish to light but rather less so. Both reacted quite well on convergence. There seemed a slight paresis of the right face, but this was difficult to establish. The tongue was furred; protruded in the midline; there was a medium tremor. There was also tremor of the lips and considerable slurring of speech as evidenced by the test phrases. This slurring was of the type usually seen in general paralysis. Vision in the left eye seemed a little defective, but owing to the mental state it was impossible to be certain of anything in which much coöperation was required. Both discs were somewhat pale but within physiological limits. The remaining cranial nerves showed nothing abnormal.

There was no evidence of paresis of the limbs and both grips were good and equal. No wasting of muscles. The deep reflexes were equal and active. Superficial reflexes: abdominals were not elicited (abdomen very flabby); both plantars gave a flexor response. There was considerable failure of coördination as evidenced by the finger-nose test, some dysdiadokinesia and, as already stated, inability to maintain an upright posture without assistance. There was a medium tremor of the outstretched fingers. Sensation could not be examined owing to the clouding of consciousness; next day, when she could cooperate better, no disturbance was found.

The pulse-rate was 70 and the radial arteries not thickened. No enlargement of heart, but sounds muffled all areas; no bruits. Blood pressure 156/90. Other systems: nothing abnormal found.

Mental state.—She was dull and lethargic; her face was stupid and heavy looking, and her words came slowly. There was some degree of agnosia. She was two days out in the date and could not furnish the time of day. She answered questions irrelevantly. There was no evidence of delusions or hallucinations. The immediate impression was that of a case of general paralysis or some intoxication.

Progress.—Next day she was slightly clearer and was able to give some account of herself. She said she was depressed and admitted drinking heavily, speaking bitterly of her husband's behaviour. She complained of memory difficulty and said she could not remember next morning what happened the day before. This was objectively demonstrable although it was not as gross as might have been expected. The disorientation in time persisted in the same degree but that for space and identity was intact. She could not reproduce a simple story told to her and missed its point. Her grasp of general information was patchy, though better than might have been expected; but she failed miserably in the simplest calculations and could not repeat even four digits backwards.

Three days after admission her speech was slightly less slurred. There was now no evidence of agnosia in any field nor apraxia; though she still spoke a little irrelevantly she remembered details of her previous conversation with me. Her mood was unstable and she readily broke down into tears, bemoaning her position. Four days after admission the slurring of speech seemed even less manifest but was still present. Both pupils now reacted briskly to light and the tremor of the tongue had diminished. Her mood was rather hostile and she spoke in the dramatically portentous manner of the slightly intoxicated. Next day there was little change, but memory tests revealed a much grosser defect of recent memory than she had previously shown. She was again friendly and cooperative. On August 2nd, 1935, it was possible to satisfy oneself that there was no disturbance of sensation, and the day after this there was a distinct improvement all round. The speech difficulty had disappeared and the tremor of the face also, whilst that of the tongue was much less. She was now correctly orientated but still failed in simple calculations. For the next week she made steady improvement and on August 10th she was correctly orientated, her memory much improved, her mood much more stable. Five days later the only remaining feature was a slight tremor of the lips; she was so much improved that she was able to go up to town and do a round of shopping accompanied by a nurse. By August 29th she made a completely normal impression, but it was found that she was still shaky in signing her name and she could not perform the finer movements such as sewing. She left hospital on Sept. 18th, as she did not wish to stay longer, completely recovered.

Serological findings on admission.—Cerebro-spinal fluid: clear and colourless apart from a few red corpuscles; cells 3 per c.mm.; 580 red cells per c.mm.; protein 0.055 per cent.; globulin, Nonne-Apelt and Pandy reactions negative; Lange's goldsol test, no change in any tube. The Wassermann reaction was negative in blood and cerebro-spinal fluid, and the latter was held to be within normal limits, affording no evidence of neurosyphilis.

The serological findings leave no alternative to the diagnosis of alcoholic pseudo-paresis, the rarity

of which in the last few years must be attributed chiefly to (1) a change in the habits of the people, with consequent reduction of the alcoholic psychoses in general, and (2) an improvement in means of precise differential diagnosis—a factor probably of equal importance. The present case demonstrates the good prognosis of this disorder and the rapid recovery following withdrawal of alcohol. The patient was seen again on Oct. 22nd and except for her worries was perfectly well.

I am indebted to Dr. J. G. Greenfield, of the National Hospital, Queen-square, for kindly carrying out the necessary serological examinations.

JAUNDICE DUE TO PHENOBARBITAL

By C. ALLAN BIRCH, M.D. Liverp., M.R.C.P. Lond.,
D.C.H., D.P.H.

SENIOR PHYSICIAN, NORTH MIDDLESEX COUNTY HOSPITAL,
LONDON

Phenyl-ethyl barbituric acid (now officially called phenobarbital) was first introduced in 1913, and has been used extensively since that time. Huddleston,¹ who reviewed the literature up to 1928, reported toxic effects in 22 out of 1000 patients taking phenobarbital, and it is now generally agreed that evidence of poisoning may be expected in as many as 2 or 3 per cent.

The toxic manifestations are similar to those of barbiturates in general, as described at length by Lundy and Osterberg² and by Gillespie.³ They include morbilliform eruptions, nervous disturbances such as vertigo, ocular disorders and coma, and certain general effects—fever, albuminuria, nausea, and vomiting. Jaundice, however, is almost unknown. Pemberton and Pearson⁴ claimed that their patient showed all the known cutaneous and visceral effects except hæmaturia, and although the liver was enlarged jaundice was absent. Scarlett and Macnab⁵ in a recent survey of phenobarbital fatalities do not mention jaundice. Huddleston¹ described more or less severe and constant epigastric pain, not responding to diet and alkalisation, in 5 per cent. of 1147 cases in which phenobarbital (in an average dose of 3 grains daily) had been given over a period of years; but none of these patients had jaundice.

There is some evidence that barbitone (Veronal or diethyl barbituric acid) can cause liver damage. Gerlach and Bredmose⁶ at the Viborg Mental Hospital confirmed the observation of Ravn⁷ that veronal damaged the liver, and found positive urobilinogen and bile-acid tests when veronal was given continuously and also (less often) when it was administered intermittently. Apparently clinical jaundice did not occur.

In 1925 Parkes Weber⁸ described the case of a choreic girl, aged 13, who developed a morbilliform eruption with jaundice and bile-containing bullæ after taking 0.1 gramme (1½ grains) of Luminal* daily for 14 days.† The stools were pale and the

* A proprietary preparation of phenobarbital.

† The dose was incorrectly given in the original paper but was corrected by Dr. Parkes Weber subsequently (*Brit. Jour. Child. Dis.*, 1927, xxiv., 328).

urine contained bile. The van den Bergh reaction was positive, and the icterus index was 40. The child was not seriously ill and had no pyrexia; the Wassermann reaction was strongly positive. The case I wish to record was as follows:—

A man, aged 50, with well-marked hyperthyroidism was admitted to hospital in order to be prepared for thyroidectomy. He was given 1 grain of phenobarbital every night, beginning on August 15th, 1935, while preliminary investigations of basal metabolism, &c., were being made. On Sept. 2nd a course of liquor iodi aquosus B.P.C. (Lugol's iodine), 5 minims three times a day, was begun. All went well until Sept. 4th when the patient had some conjunctivitis. On the 6th a diffuse macular rash appeared and phenobarbital and iodine were discontinued. He became drowsy and was strange in manner. The macules coalesced and small vesicles and pustules appeared and the mucous membrane of the mouth was affected. Itching was considerable. The temperature was remittent, 102°–104° F., and the patient obviously very ill. On Sept. 10th jaundice appeared and increased until it was very deep. The liver was enlarged about half-way to the umbilicus. The van den Bergh reaction was prompt direct positive (15 units). Bile salts and pigment and albumin were present in the

urine. The stools were pale. The Wassermann reaction was negative. The whole picture slowly subsided and by Sept. 25th his temperature was normal. Very extensive desquamation followed, and he left hospital on Oct. 26th.

Toxic symptoms appeared in this case after 1 grain of phenobarbital had been given daily for 22 days. Subsequent administration of Lugol's iodine caused no ill-effect, and hence the illness cannot be ascribed to iodine. The skin condition was typical of phenobarbital poisoning, and since jaundice occurred concurrently, in the absence of any other cause, my conclusion is that the jaundice was produced by phenobarbital.

MEDICAL SOCIETIES

TUBERCULOSIS ASSOCIATION

At a meeting of this association held on Feb. 21st the first subject discussed was

Primary Tuberculosis in Children and its Relationship to Meningitis

Dr. H. H. SCOTT said that twenty years ago it was recognised that tuberculous meningitis was usually part of a general tuberculosis, the primary seat being often in the bronchial, cervical, or mesenteric glands, by the infective material passing to the meninges by way of the lymph or blood stream. Had there been much advance since then? How did or could such a tuberculous gland give rise, by way of the lymph stream, to a meningitis? While some of his own cases apparently confirmed the prevailing idea that in blood invasion the brain or meninges was the first to suffer, Dr. Scott believed this idea to be a fallacy, in view of the numerous exceptions—e.g., cases in which the spleen, liver, and kidneys were involved, but the brain and meninges escaped. Even with focal lesions in the lungs, however, it was difficult to explain tuberculosis affecting no other secondary site. He knew of no lymphatic connexion between the lungs and the base of the brain, and one was driven to conclude provisionally, that the infection was conveyed by the blood, although, where there was extensive involvement of the meninges, invasion of other parts might have been expected. It was sometimes impossible to discover any primary focus; this might be so even in the presence of widespread dissemination (the *granulie primitive* of French writers) possibly due to a massive exogenous infection, especially in debilitated subjects—for example, as a sequel to one of the acute exanthemata. Meningeal tuberculosis might occasionally be primary, as in the case of a child four years of age in whom the meningeal tuberculosis was the only discoverable lesion. In his series of 300 autopsies on tuberculous subjects, meningeal infection was found in 41 per cent. of 225 children under ten years of age, and in 49 per cent. of 65 adults over twenty years. The distribution of the milia gave no support to the statement, frequently made, that tubercles may

often be found along the fissures of Sylvius when they are not discoverable elsewhere in the meninges. In only one case in the whole series—in a man 27 years old—a few tubercles were found along the fissures without involvement of any viscus other than lungs and pleura. Tuberculous tumours of the brain, tuberculomata, or conglomerate tubercle might or might not be associated with meningitis. They were often multiple and had a special predilection for the cerebellum, the base of the brain, and the basal ganglia. Judging from his own cases (9 in the whole series), the association of conglomerate tubercle with meningitis was largely fortuitous, and one might exist without the other until the tumour reached the surface and so came to affect the covering membrane.

Dr. C. H. C. TOUSSAINT said that tuberculous meningitis and miliary tuberculosis were metastatic manifestations of tuberculous disease and not primary forms. Usually it was possible to find at autopsy the primary site of infection. The two main sources of infection were bovine and human tubercle bacilli with their carriers. Summarising the investigations of a large number of workers in this country and elsewhere into the occurrence of bovine infection in tuberculous meningitis, the speaker said 25 per cent. had been shown to be due to bovine bacilli and 75 per cent. to the human type. The fact had thus been amply confirmed that in the primary tuberculosis of childhood human infection was of far greater importance than infection with the bovine type of bacillus. In the Lancashire investigation of deaths from non-pulmonary tuberculosis in children of 0–5 years, tuberculous meningitis accounted for two-thirds of the deaths. Dr. Toussaint showed slides giving particulars of the human contacts of 80 children aged 0–10 who died from tuberculosis in Bermondsey during the years 1928–35. The probable human source of infection was found in 46 out of 54 cases in which complete investigation was possible. Early notification was of vital importance to enable the tuberculosis officer to investigate the source of infection, but it should not be forgotten that notification should be made only on definite evidence of tuberculous disease. In cases of tuberculous meningitis or miliary disease, it was often difficult to establish a true diagnosis, but

increased use of chest radiology in such children should be of considerable assistance. In prevention, bearing in mind that the major problem was the danger of human infection, there were three main lines of procedure: immunisation of children exposed to risk; boarding-out of contacts; and—perhaps most important of all—the segregation in institutions, if possible, of patients with tubercle bacilli in the sputum. These must be found at as early a stage as possible and maintained in hospitals or sanatoria for as long as possible. Too often they saw a chronic sputum-positive case returned home for no other reason than that there was “no further advantage in retention.” The use of the local municipal hospital for the care of advanced cases was of great service in this respect.

Tuberculosis of Bones and Joints

At the second session the subject for discussion was the Treatment of Tuberculous Lesions of Bones and Joints.

Sir HENRY GAUVAIN said that there was one point of fundamental importance to be remembered—that a tuberculous bone or joint lesion was an osteitis or arthritis occurring in a tuberculous patient, or in other words, that it was secondary to a primary focus occurring elsewhere which might or (more usually) might not be discovered. If this was admitted, treatment logically followed on two lines, local and general. Radical treatment of the local lesion, by which he meant extirpation of the lesion, became less often indicated, although it was still of value in certain circumstances such as tuberculous disease of the knee-joint in an adult. As a rule conservative treatment was called for, and this, in the case of tuberculous disease of bones and joints, might be defined as the adoption of all measures which tended to improve the patient's health, to increase his powers of resistance to tuberculous disease, and to preserve or restore the part attacked; while sometimes it might be wise also so to fix the lesion by operative treatment that the affected part was immobilised and later risk of deformity or disability minimised—the treatment still, however, being strictly conservative. In children suffering from advancing and progressive spinal caries he would unhesitatingly avoid bone-grafting or fusing, since mechanical immobilisation alone would almost always result in cure. Later on, after successful treatment, if the patient had poor dorsal musculature and could not have satisfactory after-care supervision, a bone-graft was definitely indicated. Even in adults, osteosynthesis should only be performed when the disease was becoming quiescent. In tuberculous disease of the hip, where adequate conservative treatment was undertaken and efficient after-care given, operation was not as a rule called for. In any case he did not favour operative treatment in the acute stages of hip disease, nor in any case of tuberculous disease of the knee-joint in children. In adults with tuberculous knee-joints he usually favoured excision. Turning to general and adjuvant treatment, Sir Henry said that climatic and seasonal changes were of value to the patient, producing varying stimuli which were of great assistance. Sun-bathing, light treatment, and sea-bathing were also helpful in suitable cases and in suitable dosage. But though open-air treatment was now advised by general consent, many wards designed for the purpose were miserable and cheerless structures. To make such wards completely open on one side was not only unnecessary, but sometimes even cruel.

A folding wall on the south side which could be instantly opened or closed was preferable.

Mr. G. R. GIRDLESTONE said he fully appreciated the fundamental consideration underlying the conservative treatment of tuberculous disease of bones and joints, in that it was a local manifestation of a general disease; and he entirely agreed that a long period in hospital such as was rendered necessary by the conservative treatment was of immense advantage in countering the general disease and ought not to be cut short by operative measures which led to either the excision of the diseased focus or the arrest of the diseased focus by some form of fusion operation. This long period in hospital, whether or not the treatment was purely conservative, was especially advantageous to children, both because in childhood lymphatic tuberculosis was far more likely to be still active and even widespread, and also because they thrive under prolonged rest, in a well-run open-air hospital. For patients above the age of twenty these special considerations no longer applied, and the economic factor had also to be reckoned with. Those who favoured purely conservative treatment had, he thought, been biased by statistics based on cases many of which were probably not tuberculous at all; or on cases which for reasons of distance or age never returned to the hospital and were set down on the records as cured. The reasons for deciding on an operation were: the preservation of life (e.g., amputation in middle life for proved and active tuberculosis of hip or knee, or wide excision in the presence of persistent sepsis added to tuberculosis); the elimination of persistent disease (e.g., in proved active tuberculosis of elbow or shoulder in or after middle life); and the aim of “a permanently safe and useful limb” (Lovett), including the spine. The decision here depended largely on the extent of destruction and the mechanics of the limb or body in relation to the site of disease. A further object of operation was to save time in bed (e.g., in adults in whom the joint focus had outlasted all signs of lymphatic tuberculosis due to mechanical strain). But where the joint disease was of comparatively recent origin, indicating therefore active lymphatic tuberculosis, there could be no cutting short of general treatment. This reason, therefore, could only apply in a strictly limited field.

SOCIETY OF RADIOTHERAPISTS

At the first scientific meeting of this new society, held on Feb. 21st, the chair was taken by Dr. G. B. STEBBING, the president, and Mr. GEOFFREY KEYNES opened a discussion on the technique of

Radiotherapy in Carcinoma of the Breast

which has not been previously treated. He found it difficult, he said, to adhere strictly to the title, for he regarded radiotherapy as a method to be used in conjunction with other methods; sometimes surgery was the right treatment, sometimes surgery and radium, sometimes X rays, and sometimes radium alone. Radiotherapeutic technique had been retarded by the custom of confining it to late and advanced cases, because the patients died from metastases before the local effects could be assessed. He recognised more and more the limitations of radium, which would not give greatly better results than good surgery. He therefore used surgery before radium more often than in the past. It was important to recognise that radium was a strictly local method

and many patients did better if it were only used to clear up after surgery. Patients with supraclavicular extensions were unsuitable for radium and did better under a full course of X rays. The limitations of radium were difficult to define; it had not great penetrating power and its effect could be to some extent gauged by the size of the tumour. The palpable part, however, was by no means the whole, and the entire gland must be treated. Mr. Keynes preferred interstitial application because of the inevitable damage to superficial tissues caused by external radium. The radium must never be distributed in cartwheel fashion round the growth but in parallel lines right through the mamma, in order to produce a perfectly uniform field of radiation. If the needles were placed in a grid on a rigid framework, an almost mathematically uniform field could be obtained, but natural contours and variations in thickness interfered with such rigidity; the breast was not a pancake and greater penetrating power was needed in the centre. A more difficult problem was the treatment of the axilla; results had, however, shown that satisfactory irradiation was possible. A needle was introduced along each wall—at least four needles—and often one or two more, converging to form a cone of needles enclosing the axilla. A few long needles might be put down through the pectoral muscle from above, overlapping the others and increasing the intensity in the apex. At least 6 mg. was placed above the clavicle for prophylactic reasons, in the absence of gross manifestations of cancer there. Results had shown, in 148 patients, five-year results closely corresponding with those of surgery. No attempt had been made in this series to dissect the axilla—which often failed, and did more harm than good.

Dr. W. M. LEVITT dealt with X ray treatment as carried out at St. Bartholomew's Hospital—a modification of the glancing or skimming method introduced independently by Finzi and Holfelder. They had two plants; in one they used 200 kv. at 8 ma. at 40 cm. f.s.d., the output being 25 r. a minute. Applicator openings measured 27×18 cm. In the other plant they used 320 kv. at 50 cm., producing 15 r. per minute. Powder had been found better than wax for secondary radiating purposes; it must have a specific gravity of 1 and must have such coherence as to be mouldable. A mixture of sodium bicarbonate, two parts, to one part of Fuller's earth was used, sewn into mackintosh bags. For the anterior field one edge of the applicator rested on the midline of the chest and protective rubber was laid over the chest, humerus, and applicator mouth to limit the field. The posterior field was difficult and important. The applicator entered from behind the axilla, so as to irradiate the axillary contents. The ray must be pointed slightly upwards. There was deficient irradiation below and above the clavicle from these two fields, and this was compensated for by a third field from above the shoulder. The applicator for this field was 5 cm. shorter than the required focal skin distance. The dosage was so arranged as to make the irradiation of the whole area uniform.

The treatment took just under three weeks, one field only being treated on any one day and treatment given daily. The total dosage to the anterior and posterior fields was 1800 r. each and 1600 r. to the supraclavicular field. On the other plant the dosages were 2100 r., 2100 r., and 2000 r. over a period just under a month. In the delto-pectoral region there might be a deficiency if the arm was very mobile, but otherwise irradiation was uniform. The tissue dosage was about 2500 r. or 2900 r. everywhere.

Dr. RALSTON PATERSON described the three main techniques in use in Manchester: amputation plus radium implantation, radium treatment only, and X ray treatment alone. In so far as the radium implant was combined with a radical amputation at the time of operation, the first of these techniques legitimately came within the scope of the discussion. The general idea underlying this method was to irradiate all the gland-bearing areas just beyond the actual wound zone, but to avoid any implantation into the wound itself. Such gland areas included the apex of the axilla, the supraclavicular region, the intercostal spaces, and an implant extending down the rectus sheath from the wound. Although theoretically sound, he was doubtful whether the method actually improved the results of surgery to any greater extent than could be achieved by a radium implantation alone. The second method in use was called a Keynes's implant, and followed, with certain modifications, the original technique published by Mr. Keynes, a technique which the speaker considered a definite contribution to radiotherapy. The modifications had been introduced in order to achieve a complete implantation of the whole mammary gland, to amplify implantation of the apex of the axilla, and to extend the scope of the intercostal implant. In Manchester they had not met with any misadventures as a result of the retro-clavicular implant used to reach the upper part of the apex of the axilla.

Dr. Paterson then presented an analysis of all published figures showing the various results of surgery, radium, and X rays in treatment of breast carcinoma, the striking point of the analysis being the unusually good results which appeared to be obtained in a considerable number of foreign clinics by means of X rays alone. As a result, in Manchester they had been developing an X ray technique *pari passu* with the radium technique. Several different field arrangements were used, all of them based on the fundamental tangent principles, the dose given amounting to some 4000 to 4500 r. throughout the whole breast, and the reaction being carried to the stage of a vigorous moist desquamation. A slide was shown illustrating the very definite white blood count drop occurring as a result of intensive radiation therapy. The drop was most marked in the lymphocyte count.

Dr. FRANK ELLIS said that in Sheffield Mr. Keynes's technique was followed, except that the axillary dose had been found too large, leading to skin atrophy and late reactions. He had therefore started irradiating this area with needles in two planes, one in front and the other behind, 600 r. being given to each field when the patient was subsequently to undergo operation.

Dr. DOUGLAS WEBSTER said he had dealt with 350 primary cases and some patients remained perfectly well after ten years although their dose of radiation would now be considered quite insufficient. No doubt sensitivity varied in different individuals. He considered that the Finzi technique did not bring in the axilla satisfactorily and he supplemented it by an American method, using three or four fields converging on the breast. It was important to avoid damage to the heart when treating cancer on the left side.

Dr. N. S. FINZI said that the maximum dose with the three-field method was delivered where it was most needed: in the apex of the axilla and just above the clavicle. He sometimes rotated the centre axis during the course of treatment so as to get even

irradiation. He thought that radium had a more marked effect on a growth than X rays, especially if it were a resistant growth. One case had recurred after 200 kv. irradiation and had cleared up again, at any rate temporarily, with 300 kv. That was why he was trying to push the voltage still further.

Dr. J. S. FULTON thought that the problem of irradiation of intercostal spaces was best met by using a field 15×7 cm. which would embrace the intercostal region on both sides.

The PRESIDENT pointed out the importance of using any method, even splinting, to keep the patient still while treatment was going on, and said that his aim was to deliver 3000 r. in ten days and 4500 r. in three weeks according to size. He usually employed only two fields, but sometimes four converging on a large breast and five in the axilla. If any appreciable growth was left after treatment of this kind he treated it by interstitial radium.

ROYAL SOCIETY OF MEDICINE

SECTION OF RADIOLOGY

At a meeting of this section held on Feb. 21st the chair was taken by Dr. C. G. TEALL, the president, and Prof. H. CHAUL (Berlin) read a paper on some

Recent Developments in X Ray Therapy

He discussed short-distance low voltage high dosage therapy, designed to replace radium. Its superiority was due to the physical properties rather than to the quality of the rays. A voltage of 60,000 volts with a two-inch focal skin distance was employed. The small focal distance was obtained, he said, by using a monopolar X ray tube of unusual design. At 3 cm. depth the intensity was still about three-quarters that at the surface. The aim was to give a high dose to the disease centre while sparing the surrounding and underlying healthy tissue to assist in the cure. Ulcerated and infiltrated and deep-seated tumours, not amenable to other treatments, could be treated. For cancer of the rectum, the lower part of the sacrum must be removed and the rectum opened up. Four cases had been so treated and all remained free of primary symptoms. Prof. Chaoul showed statistics of cancer of the lip, skin, and mouth treated by his method. Of 109 cases in the skin, 93.5 per cent. had given success; for cancer of the lip the figure was 88.5 per cent. of 26 cases; for the oral cavity (28 cases), 53.6 per cent.; and of 12 melanoblastomata, 83 per cent. had recovered. Sixty-three per cent. of sarcomata also had been successfully treated. The method was contra-indicated in tumours of large size or with many metastases, or after intensive X ray or radium treatment by other techniques.

Prof. Chaoul illustrated his technique by a cinematograph film. This emphasised the sharp energy gradient, the area of irradiation limited to 9–25 sq. cm., the daily fractionated dose of 350–500 r., each application lasting only two to four minutes; and the total dosage of 7000–8000 r. spread over two or three weeks. It also showed the applicators and the results of treatment in a number of cases. In conclusion, he pointed out that there was not enough radium to treat all the patients for whom it was indicated, but this method was available to all countries, even the poorest.

Dr. J. F. BROMLEY sketched the history of short-wave therapy and considered the pathological aspect of the problem. There was no difference between

the effects of varying wave-lengths; the important factor was the energy absorbed per c.cm. and the time spacing. The claims made by the supporters of this technique were: (1) The distribution of radiation was similar to that from surface applicators, and many patients could be treated in a short time with less cost than by radium. (2) The healthy tissues were spared, and the total dosage was of little importance provided the fractioning was kept up properly. Coöperation between radiologist, pathologist, and physician was essential. The limit of the practical depth dose was $1\frac{1}{2}$ –2 cm. At first sight the preservation of healthy tissue seemed very attractive. Much work had been done on the effect of radiations on cancer cells, but less on the normal cell. Satisfactory healing depended on radio-sensitivity, good blood-supply, and healthy surrounding tissue. If, however, Sampson Handley's theory were true, it would be desirable to irradiate surrounding tissues as widely as possible. The giant cells which appeared around tumours attacked cancer cells on one side and were attacked by reticulo-endothelial cells on the other side. The effect of radiation on them was not fully understood; they seemed to show no reaction. It seemed therefore that the natural defence against cancer depended on several factors and that the effects even of heavy radiation resembled closely those of the body's own defence mechanism, and were not so damaging as might be imagined.

Another argument in favour of the Chaoul tube, however, and one insufficiently stressed, was its great convenience. Of 70 cases treated in Dr. Bromley's department at the General Hospital, Birmingham, 22 had recovered and 37 improved—results so good that the method was now a routine for rodent ulcer, only one sufferer from which had become worse. The method was also satisfactory for carcinoma of the vulva. Skin recurrences after cancer of the breast were being treated, with gratifying results. Doses comparable with those of radium therapy were well tolerated. The method filled a very definite and useful place in radiotherapy and offered a valuable sphere of research. It hardly replaced high voltage radiation, and did not absolve the radiologist from giving the usual care to glandular and other areas.

Prof. J. WOODBURN MORISON said that the apparatus he used was simple and easy to handle and gave no trouble, whereas high voltage tubes gave a great deal of anxiety and trouble and were not really practicable for routine work in a hospital. The million-volt plant seemed to work better than the 400-volt. Clinical results from low voltage therapy could undoubtedly be obtained. It was interesting to find the absorption so comparable with that from a radium applicator and even somewhat comparable with the one-gramme bomb. Work at the Cancer Hospital confirmed Prof. Chaoul's results, but the problem of metastasis remained. Where there were metastases there was eventual failure of any method. The problem of cancer therapy was the problem of accessibility. Some observers thought the stomach and cæcum could be exposed, without danger, long enough for the necessary irradiation. One day perhaps the oesophagus would also be exposed. The real justification of radium bombs would only be established when they could treat cases at depth—through the abdominal wall, for instance. Education of the public was still necessary in order that cases might be treated earlier. A great deal of research was also needed. The low

voltage apparatus would be especially suitable for tropical regions, where a great deal of skin cancer was encountered. Prof. Morison concluded with a review of a number of successfully treated cases.

Dr. DOUGLAS WEBSTER expressed his interest in the method, and asked Prof. Chaoul if it had been used in benign conditions, for example, the treatment of tonsils.

Prof. CHAUL, replying through Dr. E. W. Twining, said he had used the method for tonsils, a two-minute exposure every day for four days under local anaesthesia yielding excellent results.

MEDICAL SOCIETY OF LONDON

At a meeting of this society on Feb. 24th Prof. G. E. GASK, the president, took the chair, and a discussion on

B. coli Infections of the Urinary Tract

was opened by Lord HORDER. Additional knowledge, he said, justified another discussion on this condition, which was common and intractable. The discussion would be limited to aetiology and treatment, which went hand in hand. Lesions of the urinary tract fell roughly into two main categories: foci of sepsis and obstructive anatomical defects. It was vitally important to realise that in both categories the lesion might be small and easily overlooked or thought too trivial for treatment, but in this domain nothing must be regarded as trivial. It was not likely that the last word had been heard either of the incidence or of the variety of these lesions. The urgent thing was to recognise them and to hope that more and more of them would be remediable. It might be that by reducing the load of possible infection it would prove possible to cut in between the point of non-infection and of infection. There might be a sort of threshold of infection determined by congenital defects and by residual acquired pathological defects. Congenital defects might be absolute or relative. The discovery of certain congenital abnormalities which predisposed to infection was disturbing, as was also the realisation that the renal calyces had sphincters and that there was a peristalsis and a potential antiperistalsis in the ureters. In fact it was disconcerting as well as disturbing, for here were the materials for functional departures from normal. A prolonged spasm of one of the sphincters, or persistent antiperistalsis, might cause retention, which in its turn might prove an important factor in inducing infection by coliform organisms. There was general agreement that thorough drainage must be established if the urinary tract was to be guarded against infection from foci such as the appendix, gall-bladder, and diverticulitis. The tendency to infection from general gastro-intestinal defects, such as enteroptosis, undoubtedly existed but the mechanism was less certain. Agreement ceased even on the premiss that a causative relation existed between urinary infections and colon stasis and constipation. Efforts to act rationally in assessing values for the relationship between intestinal stasis and other diseases had been hopelessly countered during the past 20 years by that wave of pseudo-scientific opinion which linked the hygienic salvation of the race irrevocably with an artificial and forced evacuation of the bowels several times a day. There had been recently some refreshing and constructive

criticisms of this attitude. Dr. Geoffrey Evans had observed that diarrhoea was much more often complicated by pyelitis than was constipation.

There was general agreement on most points of the treatment, but the majority of writers said that fluids must be pushed from the first, and the speaker regarded a distended and splashing stomach as a quite unnecessary addition to a very uncomfortable inflammation. It was no use attempting to flush the apparatus until the renal tissue was ready and willing to be so treated. The generally accepted indications for a thorough investigation of the urinary tract were: (1) the general survey suggests that a lesion is present; (2) an acute infection threatens to become chronic despite thorough medical treatment; (3) there are intermittent symptoms despite a medical routine calculated to keep the general health sound and the bowel function at its best; (4) medical treatment fails and the condition becomes chronic. In the chronic case the aim must be the production of a soft, formed stool of reasonable bulk. Milk was to be avoided even in acute cases, but apparently it was the casein residue which did the harm, since junket and cream did not have the same baleful effect. Game, rechauffé dishes, and salted meats and fish were to be avoided, and eggs and butcher's meat excluded for a time. An increasing bulk of soft celluloses (sieved root vegetables and dried fruits) was added. If laxatives were needed agar-agar or paraffin was suitable. Lord Horder had not seen any lasting good results from colon irrigation, and his experience of sour milk and *Bacillus acidophilus* had been disappointing. He still advocated antigen therapy in certain chronic and intermitting cases.

DISCUSSION

Dr. S. A. MILLEN uttered a plea against the hazardous use of acidification therapy. It was, he said, practically important to ascertain in each case whether the infection was ascending or blood-borne. The normal tract would drive out organisms by flushing; acidification would help even the abnormal tract to free itself of infection. The difficult task was, however, to prevent reinfection. In rather more than 50 per cent. of children and 40 per cent. of adults urinary obstruction, with consequent stasis, was associated with infection. Inflammatory foci were either intrinsic—e.g., tuberculosis and neoplasm—or extrinsic, including such causes as an infected cervix. This predisposed to urinary tract infection for two reasons: the female external meatus was constantly bathed in bacterial secretions, and, secondly, the urethra and bladder base were in a state capable of providing a suitable nidus for infection. The analogue in the male was the infected prostate. Instrumentation, whether by the urethra or the ureter, was always unpleasant and dangerous, and should only be used if a case had lost ground under adequate medical therapy; ureteric stasis was one indication, and another was an infective process due to incomplete emptying of the bladder behind a large prostate or incomplete emptying of a renal pelvis, when drainage was urgently called for.

Dr. CUTHBERT DUKES remarked that if *B. coli* was introduced deliberately into the bladder of 100 healthy people only a small proportion would develop the infection. It would be interesting and instructive to discover why some persons became infected and others not. Such an experiment was provided daily by patients suffering from post-

operative retention of urine lasting for three or four days. Bacteria were almost always present in the stagnant urine. It did not matter whether they were introduced by the catheter or by the kidney or lymphatic channels. Observations on 214 such cases showed that infection was accompanied by a sudden rise of temperature about the fourth day. About 46 per cent. developed *B. coli* infections: 59 per cent. of the women and 36 per cent. of the men. Urinary infections depended on defective function of the urinary organs, and any factor which disturbed the normal mechanism of urination would increase the likelihood of the infection.

Mr. H. P. WINSBURY-WHITE stated that all chronic cases of urinary tract disease tended to become complicated by *B. coli* infection but a large group remained which did not fit into this category. In the former group a mixed infection often preceded the coliform infection—i.e., by staphylococci, streptococci, and diphtheroid bacilli. This prepared the ground for the implantation of the coliform growth. Chronic frequency in women sometimes developed into acute pyelonephritis and sometimes settled down into a chronic *B. coli* infection. A single examination often revealed a sterile urine but a second test might well show a mild infection. In many cases of staphylococcal abscess of the kidney the urine was sterile or contained only *B. coli*. Caution was therefore necessary in interpreting a sterile urine. Cystoscopy and urethroscopy frequently gave the lie to the negative urine test. Several groups were recognisable among children—e.g., the *B. coli* infection of the urinary tract which supervened upon a respiratory tract infection by cocci. Gastro-intestinal disease, impetigo, and other chronic skin lesions often set up a chronic infection, and persistence of infection in these cases called for investigation of the urinary tract for abnormality. The commonest finding was dilatation of some part of the tract. Phimosis, balanitis, and other local conditions of the tract in children might be responsible.

Dr. O. E. J. MCOUSTRA confessed to bewilderment. He had considered, he said, that the origin of the *B. coli* infection must lie in the alimentary rather than the urinary tract, but the results of a series of test-meals in cases of *B. coli* infection had been completely negative and no common factor had been discernible. One remarkable case in a man of 35 with chronic nasal and pharyngeal catarrh who had an acute attack of *B. coli* infection had been completely and finally cured with potassium citrate.

Mr. E. M. RICHES maintained that the first essential of successful treatment was accurate diagnosis. Acidifying remedies, particularly mandelic acid, gave excellent results in some acute and serious cases, the patient showing an immediate response provided that there was no anatomical abnormality of the urinary tract.

Dr. P. H. MANSON-BAHR said that *B. coli* pyelitis often accompanied malaria and was a consequence of it. More frequently it was a sequel of bacillary dysentery. An investigation he had performed during the war showed that some 80 per cent. of chronic cases of bacillary dysentery also had *B. coli* infection, and he had traced the course of the infection from the bowel wall through the glomeruli of the kidneys—a proof that the disease was blood-borne. He had also isolated the organisms from urine or blood cultures—the true *B. coli* of Escherich and its variations. He had cured with mandelic acid what he considered a unique case of severe anaemia due

to *B. coli* infection in a man who had lived in the tropics. Abnormality in the tract must, of course, be eliminated. It was not necessary to produce acetone and oxybutyric acid in order to succeed. Albumin and hyaline casts were not necessarily an indication for stopping or modifying the treatment. There was no foundation for the belief that mandelic acid therapy, even if prolonged for two or three weeks, led to anything like chronic nephritis.

Dr. JOUKES maintained that, whatever the difficulties might be in manufacturing a bacteriophage effective against streptococcal strains, it was fairly easy to produce one that would combat the coliform group. It was necessary to find a specific phage; the stock commercial virus phage usually gave no result at all against *B. coli*. The phage was now generally instilled into the bladder and left as long as the patient could retain it.

Sir RUSSELL WILKINSON described the case of a married woman with chronic pyelitis who had been unsuccessfully treated with alternate alkali and hexamine mixtures and had aborted a recent pregnancy. She was now in the nineteenth week of treatment by mandelic acid. He had hoped to be able to report that she had been successfully delivered of a normal baby, but her labour was in fact due that evening. Whenever the acid was withheld the urine had become offensive. No renal elements had been found throughout the course.

LIVERPOOL MEDICAL INSTITUTION

At a meeting of this institution on Feb. 6th, with Mr. G. C. E. SIMPSON, the president, in the chair, a paper entitled

Kidney Pain and its Treatment by Renal Denervation

was read by Mr. J. B. OLDHAM. Section of the renal nerves, he said, resulted in increased flow of the blood to the kidney, secretion of a larger quantity of urine of low specific gravity (comparable to that of ordinary diuresis), relaxation of the sphincteric muscles surrounding the papillæ and calices and uretero-pelvic junction, and anaesthesia of the kidney. Animal experiments and operations on the human kidney had proved that denervation has no untoward effects, and the operation had been suggested for the treatment of nephralgia, essential hæmaturia, non-mechanical hydronephrosis, reflex anuria and oliguria, certain forms of nephritis, arterial hypertension, and early renal tuberculosis, and also as a substitute for nephropexy and to prevent the re-formation of calculi after nephrolithotomy. The results of Mr. Oldham's own operations and those of Papin, Harris, Hess, and others showed that, whatever the cause of renal pain, removal of the nerve-supply of the kidney made relief entirely probable. Non-mechanical hydronephrosis, he suggested, was due to overaction of the sphincters of the renal calices and pelvis, and he showed radiograms demonstrating cases in which as the result of denervation pain had disappeared, renal function had improved, and the normal shape of the pelvis and calices had been regained. He agreed with Muschat that essential hæmaturia was often due to congestion of the renal papillæ by overaction of the sphincteric muscles surrounding their bases, and described two such cases in which pain and bleeding had been cured by denervation. Mr. Oldham held that the

usual operations for nephroptosis, in which the kidney was anchored to the last ribs, were unphysiological; for normally the kidney, unlike the ribs, moved downwards on inspiration. The results were not infrequently good, but the benefit was due to the surgeon having unintentionally denervated the kidney when he was fixing it. He himself operated only when there was evidence of pelvic stasis and after a prolonged trial of conservative measures, and he would not consider operation where there was general visceroptosis or marked neurasthenia. But in suitably selected cases denervation seemed to offer a certain cure. He had performed denervation seven times when removing calculi from the kidney in the hope that the consequent diuresis might lessen the chance of recurrence. The nerves could be sectioned most certainly, simply, and safely where they surrounded the outer third of the renal artery; none ran in front of the renal vein and it was unnecessary to strip this aspect of the vein.

Mr. Oldham always operated under spinal anaesthesia, for no other form of anaesthesia gave the same access to the renal pedicle. He insisted on the importance of stripping the pedicle towards the kidney and suggested that the vein should be separated from the rest of the pedicle and retracted to one side. The nerves should be excised over a distance of about one inch, and he thought no attempt should be made to strip either the branches of the artery or the pelvis up to the hilum of the kidney since this was unnecessary and liable to cause troublesome bleeding. If aberrant renal vessels were present they too would be accompanied by nerves, which must accordingly be excised, but it should be remembered that the renal arteries were end-arteries, so that ligation of an aberrant artery inevitably led to partial necrosis of the kidney. After the vessels of the pedicle had been stripped as clean as possible they were painted with 10 per cent. carbolic, which not only destroyed the finer nerve-fibres but whitened any large fibres which had not already been divided and so allowed the surgeon to pick them up and divide them. After operation there was severe pain for two to three days and for the same time the amount of urine was diminished. After a few days the urine increased and examination showed that the denervated kidney was secreting more than the normal one. The excretion of indigo-carmin—usually delayed before operation—was also improved. These urinary changes gradually lessened and after 3-6 months the secretion of the two kidneys was usually equal. In every case before operation retrograde pyelography reproduced the pain of which the patient complained, even on the injection of small quantities of opaque medium. In every case after operation the kidney was quite insensitive to overdistension and 30-40 c.cm. could be injected without the patient being conscious of it. Within 6-12 months, however, there was a slight recovery of pelvic sensation; it was still impossible to produce typical renal colic with nausea, but the injection of large quantities into the renal pelvis caused an ache in the loin. No patient had had any recurrence of symptoms.

In all Mr. Oldham had performed renal denervation 40 times, but cases treated during the last year and patients on whom other operations had been performed on the kidney at the same time as the denervation were omitted from the discussion of the results. On the basis of the results obtained in 28 remaining cases, he contended that if cases were properly selected and an adequate denervation was performed, relief of the patient's symptoms was certain.

Mr. C. A. WELLS agreed whole-heartedly with what Mr. Oldham had said. He had himself performed the operation of sympathectomy on the kidney some 30 times, and had on the whole been delighted with the results. There could be little doubt that it offered hope of relief to many sufferers for whom otherwise little or nothing could be done. Careful selection of cases, however, was very necessary, and it was essential to exclude, by every possible means of investigation, other causes of renal pain. Like Mr. Oldham, he had relied mainly upon the reproduction of pain by means of retrograde pyelography; patients were usually able to express a definite opinion upon the resemblance or otherwise of this pain to that of which previously they had complained. Having established the diagnosis it was his custom to discharge his patients for 3-6 months' observation and treatment, after which, if their history remained consistent, the investigation was repeated and the operation performed if the indications seemed sound. In cases of hydronephrosis with gross dilatation he had employed a modification of Thomson-Walker's plastic operation in conjunction with sympathectomy.

Misleading Cases

Dr. S. BARTON HALL read a paper entitled *Misleading Cases or Psychological Investigation as a Diagnostic Measure*. He had arrived, he said, at two general conclusions: first, that clinical examination at the hands of the patient's own doctor was often difficult to make effective in the nervous patient, owing to a mistaken and misleading modesty, if not actual though unintentional concealment, on the patient's part; secondly, that the time had passed when the physician relying upon clinical acumen alone could feel, with any degree of assurance, that as a result of thorough examination of the patient he had excluded organic factors. Three postulates must be satisfied before a diagnosis of functional disease could be made: (1) the case must prove negative to all laboratory and clinical investigation; (2) a positive psychogenic basis must be found; (3) the psychogenic factor must bear direct relation to the patient's symptoms. Even were all these conditions fulfilled, such a diagnosis could not be made with certainty. The speaker thought that psychological investigation might assist in diagnosis from two aspects—notably from the knowledge gained with regard to types of individual and from the result of detailed investigation of the particular case. He pleaded for the subjective method in investigation since it might provide evidence of organic disorder at a much earlier stage of the disease. Dr. Barton Hall gave the results of psychological investigation of a series of 1000 cases referred in the routine manner—500 from hospital and 500 from private practice. In all, 67 (15 per cent.) of these ultimately proved to be organic in nature, the number of hospital cases (44) being approximately double the number of private cases (23).

ONE HOSPITAL SERVICE FOR MANCHESTER.—The scheme of co-operation between the voluntary and municipal hospitals of Manchester, prepared by the Joint Hospital Advisory Board, was outlined by Mr. Walter Cobbett at the annual meeting of the trustees of the Royal Infirmary. The municipal hospitals are to be divided into medical and surgical units and are to have access to the honorary physicians and surgeons at the voluntary hospitals. This idea of a common staff should, he said, lead to a better distribution of patients and to the reduction and perhaps the abolition of waiting-lists.

REVIEWS AND NOTICES OF BOOKS

Post-graduate Surgery

Vol. I. Edited by RODNEY MAINGOT, F.R.C.S. Eng., Senior Surgeon to the Royal Waterloo Hospital. London: Medical Publications Ltd. 1936. Pp. 1742. 70s. (£9 9s. per set of three volumes).

THOUGH the undergraduate student has admirable text-books to choose from, the graduate who seeks more detailed information about the management of surgical cases must consult modern epitomes or search through monographs and periodical literature for the solution of his specific problems. The aim of this work is the collection of such material in a readily accessible form wherein senior resident officers, candidates for the F.R.C.S., medical officers in the fighting services, and others who desire to keep abreast of the modern developments in surgery may find the guidance which they need in the practice of their craft. As Lord Moynihan points out in a graceful introduction, there is a real call for such a book, and the editor is to be congratulated upon the choice of distinguished collaborators whose combined experience covers the whole range of surgery, including the care of the patient before and after operation.

The first of the three volumes to reach us is devoted almost entirely to abdominal surgery, but it also contains a valuable section on anaesthesia by C. Langton Hewer whose comments on the choice of anaesthetic for operations in special regions are most helpful; also chapters on X ray diagnosis in alimentary and urinary tracts by H. Cecil Bull, and on radiotherapy by Stanford Cade and Malcolm Donaldson. It is noteworthy that Dr. Bull has confined his attention entirely to the interpretation of radiograms without supplying any details, even when cholecystography and pyelography are under discussion, about the technique of administering the appropriate opaque substances. It is doubtless assumed that the graduate will be familiar with such matters; but he would probably be grateful for a reminder.

An outstanding feature of the main part of the work is the chapter by W. Ernest Miles on the rectum and anus, but 1200 pages are allocated to the surgery of the upper abdomen. Here the coöperation of A. F. Hurst and R. Sleigh Johnson on the medical side has been wisely enlisted in the chapters on the stomach; and the contribution by A. J. Cokkinis on intestinal obstruction is deserving of special praise. This part of the work might have been improved by careful planning, judicious exclusion of non-essentials, and concise diction; there are too many "lists" of the kind favoured by the experienced examination candidate, which are of value chiefly when they are compiled by himself, and there is some lack of balance in the space allotted to the various organs. The stomach and duodenum occupy 550 pages, while diseases of the colon are dismissed in 30, volvulus and diverticulitis being allotted barely a page apiece. The chapters on ileus and on Egyptian splenomegaly are redundant, and this is not the only example of overlapping and repetition.

The opinions expressed by the several authors are in accord with the best surgical teaching, and this must be the ultimate criterion by which the work will be judged. It is specially to the credit of the editor that very little has been omitted, but it is not always easy to find the reference to a given

subject. Alkalosis, for example, is mentioned only once in the index in reference to infantile pyloric stenosis, though the more important occurrence of alkalosis in adults receives due consideration in the section on the pre-operative treatment of peptic ulcer. The illustrations are well reproduced, but the book might well have been shortened by omitting a large number of pictures with which every undergraduate is quite familiar, and many others which show in unnecessary detail the steps of operations clearly explained in the text. It is to be hoped that the editor may be persuaded in future editions to improve an already good piece of work by ruthlessly cutting down redundant and unnecessary matter so that it may resemble more closely the "friendly book of reference" envisaged in the introduction.

Disorders of Metabolism

Diagnosis and Treatment. By JAMES S. McLESTER, M.D., Professor of Medicine at the University of Alabama. London: Humphrey Milford, Oxford University Press. 1936. Pp. 318. 25s.

METABOLISM is an elastic word and the term disorders of metabolism might be stretched to include the greater part of medicine. The first problem confronting the writer of a text-book on the subject is thus that of selection. He cannot steer clear of the pancreas, for instance, in considering disturbances of carbohydrate metabolism, but one hormone leads to another, and if he is not careful he will end by writing a book on endocrinology. Prof. McLester has resisted this syren of modern medicine, however, and has held to his course. He has also discriminated between common and important conditions like diabetes and obesity, and mere interesting oddities like alkaptouria. The British reader might perhaps feel that too much attention is devoted to gout, which seems to be following typhoid and the red squirrel into extinction in this country. Perhaps the prosperity associated with economic revival will give us back our tophi.

In discussing obesity, a subject which can generally be relied upon to divide the profession into two opposing camps, the one composed of lean rationalists, the other of more rotund mystics, Prof. McLester steers an admirable middle course which should help to reconcile the two factions. His opinion that obesity causes direct cardiac damage will not be generally accepted. Exception must also be taken to the statement that "chronic bronchitis and pulmonary emphysema are occasional accompaniments of obesity, due in part to chronic pulmonary congestion of cardiac origin, and in part to the hindrance which the subcutaneous fat offers to the heat-regulating mechanism with consequent loss of protection against changes of temperature." The gross pulmonary congestion of mitral stenosis does not give rise to emphysema, and it might also be argued that a generous lining of insulating fat might assist the heat-regulating mechanisms to maintain a constant internal temperature. However, there is much still to be learnt about obesity. The insurance companies tell us that the stout are short-lived; the reason is a matter for speculation. The author rightly believes that the rational treatment should be a matter of diet and exercise, and he makes no reference to the drugs which have lately been in fashion, not always with happy results.

The section on diabetes contains a great deal of useful information; Prof. McLester is perhaps overbold in stating that the pituitary can be ruled out of the ætiology of the disease. The modern pituitary is burdened with many functions, real and reputed, but the fact that the diabetes which follows pancreatectomy in animals can be checked by removing the pituitary leaves no doubt that the latter is intimately concerned in normal carbohydrate metabolism. It cannot therefore be ignored in connexion with a state of abnormal carbohydrate metabolism, the cause of which is still unknown.

This book should appeal to the physician who wishes to use the best available methods in investigating and treating cases of metabolic disease. It is essentially practical, and details of technique and of the various diets are fully described. The clear type and the wide spacing between lines make for easy reading.

Bacteriology in Relation to Clinical Medicine

Theoretical and Applied. By M. N. DE, M.B., M.R.C.P. Lond., Professor of Pathology, Medical College of Bengal, Calcutta; and K. D. CHATTERJEE, M.B., Medical Registrar, Medical College Hospital, Calcutta. Calcutta: The Statesman Press. 1935. Pp. 599. 30s.

THIS text-book provides evidence of the strong root that pathological teaching has taken in Indian soil. Designed for senior medical students and for students of public health, it covers the necessary ground very well. Many of the most recent advances in bacteriology are described; these are selected with excellent judgment, and the student should never be in danger of losing sight of the wood for the trees. Naturally the requirements of Indian and other Eastern students are specially considered, and the student of tropical medicine will find this a useful text-book. Protozoology is not included, the authors recognising that it is too big and important a branch of tropical medicine to be treated as a sideline. It would seem ungracious to refer to the fact that the authors occasionally stumble over the niceties of English expression; at worst a venal fault—except that this takes away the finish of an otherwise admirable work. In a new work the small effort required to rectify this matter should be made. The work as a whole is a credit to Indian medical teaching and, we may add, to Indian printers and publishers, for the printing is excellent, and the profuse illustrations, many of them in colours, are beautifully reproduced.

Endocrine Tumours

And Other Essays. By FREDERICK PARKES WEBER, M.A., M.D., F.R.C.P., F.S.A., Senior Physician to the German Hospital, London. London: H. K. Lewis and Co., Ltd. 1936. Pp. 207. 7s. 6d.

WE welcome the publication of another volume of the collected essays from the pen of so wise a medical scholar and philosopher as Dr. Parkes Weber. The main essay from which the book takes its title is written from a clinical standpoint, and is admirably lucid and informative. According to his habit the author is not content to quote merely from his own experience but has drawn extensively from the literature, and no aspect of medicine, simple or complex, seems to have escaped attention. He writes with equal facility on "Change of air," on the one hand and "The theory of the leucæmias as neoplastic mutations" on the other.

The essay on thrombo-angiitis obliterans is especially interesting. It contains an account of a case he first described in THE LANCET before Leo Buerger's publications on this disease. Dr. Weber has had this case under observation for 30 years, and has watched the patient gradually recover from the condition. With characteristic modesty he disclaims all credit for the cure. Not all the essays are confined to strictly medical matters. He has something interesting to say, for example, on Savagery in Myths and Dreams and on Pathological Money. The doctor, anxious to relax after a trying day's work, will find this book sedative without being soporific.

Tropical Diseases

An Epitome of Laboratory Diagnosis and Treatment. By HORACE M. SHELLEY, F.R.F.P.S., M.R.C.S., D.T.M. & H. Eng. Government Pathologist, Nyasaland, East Africa. London: John Bale, Sons and Danielsson, Ltd. 1936. Pp. 81. 2s. 6d.

IN Dr. Shelley's words "this little book is intended to supply the busy practitioner in the tropics with simple details concerning the laboratory diagnosis and treatment of diseases common to those climes. The essentials only are dealt with. . . ." It is inevitable that the author appears to have travelled beyond his reference in certain places and stopped short of it in others. For example, the certain diagnosis of malarial infection depends essentially on the demonstration of plasmodia or pigmented leucocytes, and in the absence of both, no amount or variety of blood counting can help very much; on the other hand, the suggestion that the essential laboratory diagnosis of Japanese river fever rests upon the observation of the fact that "there is a leucopenia" under-estimates the complexity of the problem. The diagrams are poor, especially those on pp. 32 and 33, while those on pp. 14 and 64 give wrong impressions of the relative sizes of the objects depicted. In dealing with methods of treatment Dr. Shelley states that his object has been to emphasise those of proved value rather than others of doubtful benefit, but unfortunately, as he himself says, details of therapy largely reflect personal bias rather than established principles. It is difficult to judge of the extent to which this book may prove useful.

Diseases of the Skin

Third edition. By F. C. KNOWLES, M.D., Professor of Dermatology, Jefferson Medical College; Member of the American Dermatological Association. London: Henry Kimpton. 1936. Pp. 640. 30s.

SOME 14 pages of contents indicate the scope and arrangement of the subject matter of this book, which includes in addition to diseases of the skin those of the appendages and mucous membranes, and the eruptive fevers. Forty-five pages are devoted to syphilis, which in common with the dermatoses is illustrated by a generous number of clinical photographs. The value of these from a diagnostic standpoint is somewhat discounted by their small size, sufficient perhaps for indicating the sites of predilection, but not large or vivid enough to permit of a study of characteristic detail. The need for continuity of treatment in syphilis, which has been emphasised in America for some time past, receives due recognition, and a useful and easily comprehended schedule is provided on pp. 460-61. Well managed too is the article on acne. Some points

in the treatment based on theoretical considerations such as the potassium bromate content of white bread will be new to British readers, while the endocrine treatment of persistent alopecia areata, which originated largely in the U.S.A., is quoted without extravagant claims. With such modern additions it is strange that in the discussion of ringworm of the scalp no mention is made of the thallium acetate method of epilation which in this country has proved most useful in children too young for treatment by X rays. It is not easy to place this work, for while

it may be regarded as too large for the busy practitioner, its scope is hardly sufficient to serve the purpose of a text-book.

GUY'S HOSPITAL REPORTS is a quarterly journal of general medical interest directed to all professional classes. The annual subscription has now been reduced from £2 2s. to £1 10s. New subscribers are invited to communicate with the treasurer, *Guy's Hospital Reports*, Guy's Hospital, London Bridge, S.E.1.

NEW INVENTIONS

OUTFIT FOR VASOTOMY

WHATEVER objections may be raised to vasotomy in the treatment of acute gonorrhoea, few can object to it as a useful—I consider essential—measure for dealing with infection of the prostate and seminal vesicles and systemic complications arising there-

from. An account of the outfit I use for the purpose may therefore be of interest.

The needle (A) is so designed that it reduces to a

minimum the possibility of damaging the intima of the vas. The point (A1) is blunt and has an outside bevelled edge, and 1/2 in. from the point is a shoulder (A2) which prevents the introduction of the needle too far into the lumen. They can be had in four

different calibres (21 to 24 swg). The needle is fitted by a bayonet joint to a 2 in. length of rubber tubing (B) the other end of which fits by another bayonet joint to a 20 c.cm. Record syringe. This secures the absence of wobbling of the needle-point in the lumen of the canal. The bridge (C) through which the needle is passed still further secures steadiness

and also holds the needle parallel with and at the level of the lumen of the tube outside the skin surface. The vasotomy clamp (D) will be found very useful for grasping and steadying the vas during incision, and is very easily manipulated.

The outfit, which is neatly contained in a metal case (6 in. by 3 1/4 in. by 1 1/4 in.) as shown in the illustration, has been made for me by Messrs. Allen and Hanburys Ltd. of Wigmore-street, London, W.

J. F. PEART, F.R.C.S. Irel.

AN IMPROVED TYPE OF GALVANOCAUTERY

THE instrument here illustrated is particularly suitable for the treatment of warts, naevi, &c. The holder is about the thickness of a pencil and has obvious advantages over the usual type of instrument. Instead of a press switch on the handle which

in use often becomes unbearably hot, a pear switch is fitted in continuity with the wire flex about 3 ft. from the cautery handle. This switch is held and easily operated by the left hand leaving the right hand free for the careful manipulation of the cautery point.

The instrument has been made to my design by Messrs. Mayer and Phelps, New Cavendish-street, London, W.

R. T. BRAIN, M.D., F.R.C.P. Lond.

THE LANCET

LONDON: SATURDAY, FEBRUARY 29, 1936

WATER METABOLISM IN EPILEPSY

DURING the past few years the field of epilepsy research has been inundated with water. The flood reached its height a year or two ago, and, having damped the ardour of all but a few enthusiasts, has since been receding rapidly, so that it is now possible to take stock of the situation. Apart from a few damp patches, the field seems remarkably unchanged. The idea that epilepsy might have something to do with water metabolism is not new. HIPPOCRATES is credited with the statement that "whoever is acquainted with such a change in men and can render a man humid and dry, hot or cold by regimen could also cure this disease—without minding purifications, spells and all other illiberal practices of a like kind." LENNOX and COBB have aptly paraphrased this as follows: "Whoever is acquainted with physiology and can render a man acidotic, dehydrated and fully oxygenated could also repress this disease, without minding purification of narcissistic personalities, ritualistic empirical diets and all other illiberal practices of a like kind." Both the original dictum and the paraphrase have been frequently repeated, in our own columns and elsewhere, and they stand repetition. But neither the Father of Medicine nor his interpreters would be pleased to see their words construed as meaning that epilepsy is due to waterlogging of the brain. It is true that modern research has confirmed the intuition of HIPPOCRATES in that it has shown that anything conducive to dehydration—be it starvation, a ketogenic diet, or drastic restriction of fluid intake—will often lessen the frequency of fits in the epileptic, and that on the other hand forcing of fluid will precipitate convulsions. But it is a perilous jump from these facts to the conclusion that epilepsy is an expression of disturbed water balance. It would be just as logical, or illogical, to assume that because alcohol induces a state of euphoria, schizophrenia is due to a deficiency of alcohol.

Another source of misapprehension is the fact that the convulsion itself gives rise to severe though temporary dislocations of physiological equilibrium in general and of fluid balance in particular. During and immediately after convulsions the body loses a considerable amount of extracellular fluid, and this temporary dehydration is naturally followed by a reactionary phase of water retention. The body, in short, loses water during fits and recovers it in the intervals. But somehow this has been twisted round into the statement that the body retains extra fluid between convulsions and discharges it during the fit. Epilepsy is therefore due, argues the enthusiast, to retention of water. When he is reminded that

convulsions are not a symptom of oedema, he shifts ground and postulates a local oedema of the brain due to obstruction of venous return. Counter this with the fact that the tension of cerebrospinal fluid is normal in epilepsy and he falls back on local shifts of water between the neurone and its environment. Surrounded thus by the cell membrane he is safe from assault. Nevertheless the onus of proving his hypothesis rests on him; and in point of fact no single metabolic aberration has yet been demonstrated to precede the epileptic fit. The normal activities of the neurone are responsive to changes in its environment, and it is therefore no cause for surprise that its pathological activities can be similarly modified.

But while informed opinion may remain unmoved by inconclusive evidence, it must always leave some impression on the general reader who has neither time nor training to assess it at its true worth. In consequence much of the time and resources of medical research workers must be spent in disproving "theories" which ought never to have been propounded. A recent publication by Dr. H. S. TEGLBJAERG¹ is a case in point. Dr. TEGLBJAERG records the results of exhaustive investigation into all aspects of the relation of water metabolism to epilepsy, during the course of which he has carefully tested the data and criticised the conclusions of his predecessors. The net result of a great deal of expenditure of time, money, and labour is that there is no positive evidence to incriminate water metabolism in the ætiology of epilepsy, but that forcing of fluids, associated with injection of pitressin, may be useful in diagnosing the disease. Such negative inquiries seem inevitable, but one is left with a feeling of regret that the resources at Dr. TEGLBJAERG's command have had to be used to such small gain.

NON-SPECIFIC PROTEIN THERAPY

ABOUT twenty years ago it was shown that the course of typhoid fever is often favourably influenced by intravenous injections of typhoid vaccine.² It was soon found that similar results could be got with *Bacillus coli* vaccine³ or albumose,⁴ and non-specific protein therapy dates from these observations. A great variety of proteins has since been used to treat an even greater variety of conditions, both acute and chronic. The American Council on Pharmacy and Chemistry, believing that there are many proprietary preparations of this type of unproved value, and that the indications for the use of non-specific protein therapy are not widely appreciated, has recently authorised the publication of two informative articles on the subject. In the first of these CECIL⁵ provides a critical review of the whole field. The three proteins most often used in the United States are typhoid vaccine,

⁵ Cecil, R. L.: Jour. Amer. Med. Assoc., 1935, cv., 1846.

boiled milk, and diphtheria antitoxin, the latter being employed not because of its antitoxic property but because it is an available form of horse serum. CECIL thinks it very unlikely that any of the proprietary remedies offered as substitutes have any virtues not inherent in these substances, but the Gram-positive bacteria such as pneumococci are said to be less likely to cause febrile reactions than Gram-negative organisms such as typhoid bacilli, when given intravenously. It is essential, however, to distinguish sharply between the effects of intravenous and of intramuscular or subcutaneous injections. The two last provoke comparatively mild reactions, and there are very few patients indeed who cannot safely be given them. On the other hand, though such injections do no harm, they very often do no good, and CECIL believes that intravenous injection of typhoid vaccine is not dangerous, provided it is not applied to patients in a state of exhaustion, and that the first dose given is a small one. It is also wise to avoid treating patients who are known to be protein-sensitive, those who have active or quiescent pulmonary tuberculosis, and cases of congestive cardiac failure and hyperthyroidism.

It is extremely difficult to assess the merits of any form of therapy in chronic disorders, especially in those characterised by natural remissions. It is therefore not surprising that opinions about the value of non-specific protein therapy in such conditions as chronic arthritis should be conflicting, though the balance of evidence is in favour of its trial, especially in early cases. CECIL holds that the greatest usefulness of protein injections is in acute and subacute infections, and in these it is usually possible to be surer that benefit is being obtained. The method having been first applied to typhoid fever, there are numerous series of cases on record treated by protein therapy, and with great success. In pneumonia, although the statistical evidence is distinctly in favour of protein fever therapy in Group IV. cases, it is felt that this form of treatment is too drastic, especially as several fatalities have been recorded. In dementia paralytica malarial therapy holds a secure place, but although this is almost certainly a further example of protein therapy, there is as yet no certainty that injections of typhoid vaccine are equally efficient in bringing about a cure. In tabes dorsalis the results are less consistent, and in other diseases of the nervous system relief is the exception. CECIL states that protein therapy should always be considered for cases of acute arthritis, especially for those that do not respond to salicylates. The treatment of inflammatory diseases of the eye—especially acute iritis, uveitis, keratitis, and conjunctivitis—is the subject of numerous reports claiming successful results. In gynaecology, acute and subacute infections of the adnexa have often been treated by foreign proteins, and L. H. STUHLER, of the Mayo Clinic, goes so far as to say that if he were limited to one method of treatment in salpingitis, it would be this. In the treatment of allergic diseases and dermatological conditions reports are more conflicting, and

striking improvement should not be expected. Of especial interest, perhaps, is the use of proteins in the treatment of diseases of the peripheral vessels, for which comparatively little can otherwise be done. G. E. BROWN has described intravenous injections of typhoid vaccine as the best medical measure for the relief of the severe pain of thrombo-angiitis obliterans. N. W. BARKER prefers typhoid H antigen, which when injected intravenously produces fever with fewer rigors than typhoid vaccine. And though the suggested mechanism is not the same, it may not be irrelevant to recall also the impressive results obtained from the use of muscle extract.⁶

A second paper, by HEKTOEN,⁷ deals in more detail with the changes which occur in the organism in response to foreign proteins. The benefit derived bears some relation, he believes, to the degree of the general reaction and of the fever. There is a dilatation of the vessels in the splanchnic area with contraction of the peripheral vessels, and it is this which gives rise to the rigors; later this state of affairs is reversed. At first there is a leucopenia which is followed by a leucocytosis. Numerous other alterations occur in the various chemical constituents of the blood, such as an increase in the proteolytic and lipolytic enzymes. It is surprising that it has not yet been determined whether the normal antibodies and bactericidal constituents of the blood are increased in man in non-specific protein therapy, nor is it known whether in typhoid fever the production of specific antibodies is as great after typhoid vaccine has been given as after a non-specific protein. In some types of disorder, it may be, specific immune bodies are manufactured and assist the natural defences of the body; in others it is possible that the leucocytosis is the important reaction, and in yet others the fever, which by giving rise to vasodilatation floods the infected or injured tissues with antibodies. In vascular disease it is certain that the degree of vasodilatation is of prime importance, and in a sense the treatment here is specific rather than non-specific. There obviously remains a wide field for further research, not only into the practical value of the method, but also into the processes underlying it.

CONGENITAL G.P.I.

SINCE the advent of malaria therapy so much attention has been focused on acquired general paralysis of the insane that the inherited form of the disease has suffered relative neglect. At a meeting of the neurological section of the Royal Society of Medicine on Feb. 20th a clinical demonstration of cases of congenital G.P.I. treated at the Maudsley Hospital was therefore welcome and provided the basis for a lively discussion. Some 27 patients thus afflicted had been under the care of Dr. T. TENNENT during the last nine years. Of these 9 belonged to a group for whom no form of therapy offered any hope, some degree of amentia being present. In the remaining 18

cases the child was normal until the development of the clinical picture of G.P.I.; of these, 14 had received malaria plus tryparsamide, with the result that 5 had improved to an extent which made them fit to remain at home and to assist in household duties—a result as gratifying as it is unusual; 4 had made slight improvement, 2 remained stationary, 1 was in a mental hospital, and 2 had died. The incidence was the same in both sexes; in 16 cases syphilis could be definitely traced to one or other parent, and in 7 one or other parent had G.P.I. (6 fathers and 1 mother). In one of the families there were 3 juvenile victims of G.P.I. The diagnosis was made on a fourfold basis—history, mental picture, and the neurological and serological findings all being considered. The treatment adopted in suitable cases consisted of induced malaria (8 rigors) followed by repeated courses of tryparsamide. The older the age of onset, and the shorter the time during which symptoms had been observed before steps were taken the more favourable appears to be the prognosis.

Another series of treated cases was described by Dr. W. D. NICOL and Dr. E. L. HUTTON in a joint communication from Horton. Over a period of ten years they had 16 such cases (2 boys, 14 girls) of whom 7 were dead. As in the Maudsley series congenital stigmata were comparatively rare, the incidence of pupillary changes was extremely high, and slurred speech was common; fits occurred in half the cases, but none had tabes. All but one of the cases had malaria treatment; salvarsanised serum had been given to 2 patients and arsenical treatment to 4 others, but none had had tryparsamide. Serological findings were positive in every case, and in 9 there was evidence of syphilis in parents, 4 of whom had developed G.P.I. Results of treatment were disappointing; in only one case had the progress of the disease been arrested. Three patients were still alive 15, 11, and 10 years after the onset of symptoms; one of these was now held to be suffering from neuro-syphilis rather than G.P.I. Diagnosis indeed seems to be a difficult matter, since other neuro-syphilitic manifestations such as epilepsy and meningovascular disease cannot always be excluded. In the course of the discussion Dr. J. BRANDER pointed out the pitfalls which are encountered when too much reliance is placed on serological findings, in the adult as well as in the child. Even in young children, moreover, the possibility of acquired syphilis must be borne in mind, though proved instances of this are very rare. D. C. JEANS and J. V. COOKE¹ could find only 34 cases of syphilitic infection acquired between the ages of 2 and 9 in their examination of more than 75,000 children. Some of the family trees of the Horton cases shown on the screen proved to be of great interest and supported Dr. NICOL's plea for the investigation of family histories. Dr. DAVID NABARRO also emphasised the value of the information to be gained from the study of family history. His vast experience of congenital syphilis in

children, of which he discusses another aspect on p. 498 has convinced him that neuro-syphilis is far more common than is generally supposed—probably as high as 50 per cent. He maintains that the early discovery of a positive cerebro-spinal fluid demands energetic antisyphilitic treatment if the risk of G.P.I. occurring in any of these children is to be forestalled.

It is fortunate that congenital G.P.I. is a rare disease, for the general consensus of opinion appears to be that once clinical symptoms have supervened the condition is almost hopeless. Dr. R. M. STEWART confirmed this melancholy verdict as the outcome of considerable experience. W. C. MENNINGER² has reviewed records of 610 cases from the literature in none of which was treatment of any avail. H. W. POTTER³ reports 60 cases which include 6 remissions after treatment. It would appear that these together with the few shown by Dr. TENNENT are the only ones in whom any degree of improvement has been reported. It remains to be seen whether even in those 5 children the amelioration will be maintained.

PROSTIGMIN AND MYASTHENIA GRAVIS

THE nervous system contains at least three types of junction between functionally linked structures: (1) between a stimulus receptor and its afferent neurone, (2) between one neurone and another, and (3) between an efferent neurone and the muscle-fibre or other effector organ which it innervates. The separate activities of each of these structures have one common accompaniment: an electrical ionic shift that can be objectively recorded by means of suitable apparatus and which may be taken as the most reliable indicator of functional activity. A natural inference is that activity passes from each of these structures to the next in virtue of this electrical change—i.e., that transmission of activity across the junction is mediated directly by electrical influence. This simple explanation becomes less satisfactory with every addition to our knowledge of the behaviour of those functional units which embrace both discontinuous structures and the junction between them. So little is yet known of the mode of action of stimulus receptors that we have not yet reached the stage of a simple explanation of the transfer of their activity to their afferent neurones, though LEWIS's suggestion that peripheral excitation of afferent neurones that give rise to pain is brought about by the liberation of histamine or of some pharmacologically similar substance is a plausible one.

To explain the observed facts of spinal reflex physiology SHERRINGTON found it necessary to hypothecate the liberation at the interneuronal junction, or synapse, of two mutually antagonistic substances—excitatory (E) and inhibitory (I)—instead of the simple transfer of electrical instability. These (E) and (I) substances still remain physiological abstractions, but the work of DALE and his collaborators has drawn attention to a

¹ Prepubescent Syphilis, New York, 1930.

³ Psychiat. Quart., 1933, vii., 593.

substance of undoubtedly objective existence—acetylcholine—which appears to provide all that our present knowledge of neuromuscular activity demands of a chemical transmitter, and it is at the moment sufficient to assume that the exciting impulse in the motor neurone causes at this junction the liberation of acetylcholine which in turn excites to activity the contractile elements in the muscle-fibre. Although this is still barely beyond the stage of an hypothesis, not universally accepted, clinical neurology has already found in it a ready explanation for one of its own particular problems—i.e., the nature and the relief of the muscular weakness in myasthenia gravis. This muscular weakness is associated with a form of myogram peculiar to this condition; the prompt and dramatic relief afforded by Prostigmin can thus be actually charted, also the gradual reversion of the myogram to its characteristic pathological form as the effect of the drug wears off and the clinical improvement disappears. There are therefore good grounds for believing that prostigmin, unlike glycine and ephedrine, has an effect in myasthenia gravis which is not merely adjuvant or compensatory, but which is concerned directly with the reversal of the change responsible for the muscular weakness. This pathological change undoubtedly occurs at the neuromuscular junction between voluntary nerve and skeletal muscle. If it is assumed that excitation is normally transferred from nerve to muscle at this junction by acetylcholine, it is to be expected that the change is concerned at some stage with the liberation, the migration, or the exciting action of this transmitter. When it is further demonstrated that prostigmin has also the property of protecting acetylcholine from destruction by the esterase normally present in the blood, its therapeutic value in myasthenia gravis is easy to understand.

In normal persons, according to this theory, the quantum of acetylcholine released by each impulse is immediately attacked and rapidly destroyed by the esterase locally present. The excitation is transferred to the muscle-fibre only when an adequate amount of acetylcholine escapes destruction and reaches the motor end-plate or whatever other structure effects the immediate stimulation of the contractile elements. In the myasthenic patient the weakness of voluntary movements is due either to the smallness of the amount of transmitter liberated by each nervous impulse, or to the over-activity of the destructive esterase, so that the transmitter does not accumulate in quantity sufficient to excite the normal number of muscle-fibres to contraction. Prostigmin presumably relieves this weakness by slowing the rate of destruction of acetylcholine, the effect being achieved either by giving extra protection to the abnormally small amounts produced, or by protecting normal amounts against destruction at an excessive rate. The latter possibility can be discarded in the light of other observations; the former fits in well with the phenomena of myasthenic fatigue as observed clinically and with the characteristic myasthenic myogram. A delay in the synthesis of the inactive precursor of acetylcholine from its

chemical components would account for the experimentally recorded abnormalities of the myogram, but would not account for the clinically observed weakness of the victims of myasthenia gravis; if we are to retain this hypothesis we must therefore make the further assumption that there is delay in the mobilisation of these components to the point where they can be used. The probability that this, and possibly other change, is present in myasthenia gravis is perhaps to be inferred from the fact that the therapeutic effect of prostigmin is limited to the very transitory relief of a symptom and does not include any favourable influence upon the course of the disease.

Another line of approach to the problem has been pursued by Lady BRISCOE, who records the outcome of her investigations elsewhere in this issue. She has introduced an entirely different conception of the essential pathological change responsible for myasthenic weakness. The hypothesis advanced by her, in conjunction with DALE, is derived from the long recognised similarity between the behaviour of a myasthenic patient and that of a curarised muscle-nerve preparation. It seems likely that curarine acts not by reducing the amount of the transmitter (acetylcholine) liberated at the neuromuscular junction, but by raising the threshold for excitation of the muscle-fibre so that a previously effective amount of the transmitter becomes no longer adequate. The question immediately arises: is the weakness in myasthenia gravis due in the same sense to a pathologically high stimulation threshold of the muscle-fibre receptor? If we adopt this view, as Lady BRISCOE has pointed out, the clinical action of prostigmin can still be accounted for, in terms of its esterase-inhibiting action, enabling abnormally large amounts of the transmitter to accumulate in contact with the muscle-fibre and thus to reach a value which is once more adequate in relation to the pathologically raised threshold. But she has shown further that prostigmin has a toxic effect on the muscle-nerve preparation which reduces both the height and the maintenance of contraction produced by repetitive stimulation of the motor nerve, and that this effect is exercised most markedly upon the muscle responses to higher rates of supramaximal stimulation. These toxic effects can be quantitatively antagonised by curarine, but they cannot be explained as due to an opposite effect—i.e., to a lowering of the muscle threshold for excitation—because the anticipated result of such lowering would be to make stimuli of subminimal strength and of any rate of repetition adequate, and to make stimuli effective at a rate of repetition too high for transmission to normal muscle. It would be equally difficult to explain the toxic effects in terms of the esterase-inhibiting action, since the anticipated effect of this would be identical with that of a lowering of the muscle threshold. Moreover, prostigmin given in this way produces, according to Lady BRISCOE, a very definite change in the uprising or tension-increasing limb of the myogram, a change which has no clinical counterpart in myasthenia gravis and for

which no explanation is available. These interesting experiments thus bring us nearer to an understanding of the essential pathological change responsible for myasthenic weakness, but not as yet to any explanation of the mode of action of the drugs which completely relieve this weakness. Any attempt that we may now make at an explanation must take into account additional effects which at present seem entirely unrelated to therapeutic

value. Indeed, so many different phenomena appear to be taking place and so many different varieties of activity have been disclosed in this zone of structural discontinuity between nerve and muscle that we cannot but regret the time when it was possible to think in terms of electrical excitation alone and to picture a succession of subdued sparks jumping across a gap which, the microscope assured us, was very small indeed.

ANNOTATIONS

EXPERIMENTS ON ANÆMIA

THE technique developed by Whipple¹ has proved one of the most useful means of assessing the value of remedies for anæmia. In his experiments dogs are given a standard diet and are maintained at a given level of anæmia by bleeding at regular intervals. The degree of anæmia—about 45 per cent. hæmoglobin—is insufficient to impair the appetite or materially affect the physical activity. The amount of blood which must be abstracted to maintain the anæmia is obviously a measure of the hæmoglobin production, and under the standard conditions the dogs produce 10 to 15 grammes of hæmoglobin a week or 1 to 2 per cent. of hæmoglobin a day. Anti-anæmic substances are tested by adding them to the basal diet and noting the increase, if any, in hæmoglobin production. The rate at which the dogs manufacture hæmoglobin is remarkable. When supplied with suitable amounts of hæmatinic material they may produce an average increment of 4 per cent. of hæmoglobin a day, with a peak output up to 10 per cent.

Whipple defines the optimum dose as the amount of a preparation which is utilised to the best advantage in hæmoglobin manufacture when added to the basal diet. As the dosage is increased beyond a certain point, which varies of course in different animals, utilisation falls off, and ten times the optimum dose gives less than twice the return in new hæmoglobin. The optimum dose of iron by mouth in a dog weighing approximately 15 kg. averages 40 mg. a day, which is equivalent to about 200 mg. in a human being. In the dog it appears to make no difference what soluble iron salt is used and ferric citrate scales are just as effective as ferrous salts. In man it is generally believed that the various preparations of iron differ greatly in availability, the average effective doses of ferrous chloride and iron and ammonium citrate being given as 200 and 1600 mg. Fe respectively.² Another difference between the dog and man is the considerable increase in hæmoglobin production when whole liver is combined with massive doses of iron. Hæmoglobin production in these dogs is likewise accelerated when amino-acids are given along with massive doses of iron. Thus there seem to be substantial differences in response to treatment between the experimental hæmorrhagic anæmia of dogs and human idiopathic hypochromic anæmia. About 35 per cent. of an optimum dose of iron by mouth in the dog is converted into hæmoglobin and about 40 per cent. of the food iron. Elvehjem³ has shown that very little of the iron of hæmoglobin and similar preparations is absorbed from the alimentary tract in rats and Whipple finds that only about 10 per

cent. of it is utilised by his dogs—a result in keeping with the low therapeutic efficiency of organic iron compounds in man. Whipple also studied the effect of intravenous injections of ferric hydroxide. Starkenstein⁴ maintains that trivalent ferric iron is therapeutically inactive, but Whipple found that it was quickly and completely converted into hæmoglobin. Efforts to determine the site of hæmoglobin manufacture met with great technical difficulties, but there is a suggestion that the iron is very rapidly taken up by the bone-marrow.⁵

Whipple has often emphasised the necessity for adequate control periods to obtain stable conditions and the long time taken to exhaust the hæmatinic stores of the organism. The importance of these points is emphasised by work lately done in Denmark⁶ on the production of anæmia in dogs by operations on the stomach and duodenum. The experiments were at first sight disappointing, since nothing resembling pernicious anæmia was produced even though the upper duodenum and the distal half of the stomach were resected—the area from which (according to Meulengracht's observations) the anti-pernicious anæmia ferment is secreted. But in a postscript to the paper it is stated that a year later, after a period of apparent recovery, one dog on which this operation was performed had developed a condition similar to pernicious anæmia.

PROGNOSIS IN THE CONVULSIONS OF CHILDHOOD

A FOLLOW-UP investigation by Dr. N. Faxén,¹ of Gothenburg, has contributed some valuable data on the prognosis of convulsions in childhood. In the period 1922–1931 the children's hospital to which he is attached dealt with 365 cases of attacks of loss of consciousness or convulsions in children. Convulsions immediately preceding death or due to some organic disease such as meningitis or a tumour of the brain were excluded. At the end of 1934 a questionnaire was addressed to the parents of the children, and the answers received form the basis of this study. Among the 365 children were 95 whose convulsions were diagnosed in hospital as epileptic. Only 15 of these 95 children could be said to be psychologically normal and free from convulsions after an observation period of at least three years; and only 9 of the 15 had had no attack since discharge from the hospital. As many as 78 of the 95 children were still subject to convulsions, 36 were mentally defective, 17 were undergoing institutional treatment, and 7 were already dead. Small as is the proportion of 15 to 95, Dr. Faxén insists that provided

treatment is skilled and prolonged, the prognosis in epilepsy beginning with convulsions in early childhood must not be considered as hopelessly gloomy. In another group of 40 cases, in which the convulsions had a psychogenic basis, the follow-up inquiries were unsatisfactory in that only 23 of these children could be traced. By far the largest group was composed of the children whose convulsions were due to some infectious disease. The follow-up study showed that 12 of these children had subsequently developed epilepsy, and 6 had shown themselves to be mentally defective. A comparison of the children in the epileptic and the other groups suggested that after the age of 4 years the prognosis in convulsions becomes progressively worse. The frequency with which they occur has some prognostic significance, for while the convulsions with an epileptic basis are usually isolated and separated from each other by fairly regular intervals, those due to other causes, such as an infectious disease, are apt to recur in frequent bouts.

SCHISTOSOME AND MOLLUSC

In a valuable article¹ entitled "the carriage of schistosomes from man to man, with special attention to the molluscs which are their larval hosts in different parts of the earth," Lieut.-Colonel Clayton Lane reviews, with additions, the most important papers on the subject which have been epitomised in the *Tropical Diseases Bulletin*. He begins by recalling how Leiper and Atkinson in 1915 demonstrated that *Schistosoma japonicum* develops from miracidium to cercaria in a mollusc, thus confirming Miyairi's previous discovery. Owing to war conditions the steps they took to identify the species of mollusc responsible were not perhaps the best possible; the molluscs were not of laboratory growth, and the method used was based upon the differential degree of attraction shown by various species for the miracidia, and upon the examination of fully developed worms in animals infected with cercariae obtained naturally from various species of snails. Nevertheless Leiper and Atkinson were in no doubt that the development of the worms was as they said, and with this conclusion there has been full agreement. Clayton Lane suggests that the best chain of facts which can be offered to support the view that a certain mollusc is the intermediate or larval host of a certain schistosome is that put forward by Gordon, Davey, and Peaston. The snails used by these workers were of laboratory growth, so that unnoted natural infection was impossible; infection was given by miracidia from eggs whose species was certain; and the cercariae coming from the molluscs gave the infection to clean animals, as was clear when worms of full development were seen in the veins. Following up his earlier work Leiper in 1916 showed not only that two sorts of eggs came from worms which, when of full growth, had a different structure, but also that the carriage of the two species from man to man took place in Egypt through molluscs which zoological grouping had placed in different genera.

Clayton Lane next discusses the statement that besides the three blood flukes of which human beings are the optimum host—viz., *S. hæmatobium*, *S. japonicum*, and *S. mansoni*—man is also the harbourer of others. This statement has sometimes been based upon the size and outline of the egg; while sometimes the morphology of cercariae which have come out of a snail has been used to put that mollusc among the larval hosts of a schistosome of

man. He draws attention to several papers on the variation in size of the eggs of a single species in various circumstances, and examines critically many others dealing with differentiation based upon differences in the appearances of eggs. Turning to the morphology of cercariae he states that unhappily there is no agreement about the anatomical details of the cercariae of the schistosomes of man, and he thinks that attempts to say with our present knowledge that cercariae coming from a mollusc are those of a certain species of schistosome, and that that mollusc is the larval host of that species, are of no value. He is forced, therefore, to the decision that at present only *S. hæmatobium*, *S. japonicum*, and *S. mansoni* come into the picture of schistosomiasis in man. The rest of his article is a concise account of the geographical distribution of the schistosomes of man and their larval hosts. Observations on the ecology of the molluscs, with special reference to their control, come in for discussion.

This review by Colonel Clayton Lane is of further interest since, apart from words necessary for biology, parasitology, and medical science, the paper is in basic English, keeping to 850 words in the general list and those in the special lists for science. In this way, the author believes, the information collected in the *Tropical Diseases Bulletin* can be made more easily intelligible to those whose language is not English.

PROGRESSIVE GANGRENE ROUND OPERATION WOUNDS

A RARE complication of operations on the serous cavities is the spread of gangrene of the skin on one or both sides of the scar. The course of the gangrenous process is rather slow, and healing by scar tissue follows gradually in the wake of the ulceration, but the advance of the process is quite relentless, until the trunk may be encircled by the ulcer, and death follows unless drastic treatment is undertaken. During the past six years 5 cases have been reported in this country; of these, 2 have died and 3 have recovered. The usual history is that of the fruitless trial of all types of local application, the onward spread of the gangrene being quite unchecked by these or by antiviral, antitoxin, vaccines, or ultraviolet light. The heroic measure, a wide excision of the edges of the wound, was necessary to ensure complete arrest of the disease and the promotion of healing. This was the treatment adopted in the 3 cases which recovered; it is the recognised treatment in America where the condition has been the subject of much discussion. Excision may be either by the scalpel or by the diathermy cautery. A trench cut an inch or so outside the growing edge of the ulcer will effectually stop its advance, and the sloughing edge can be excised at a future operation. The infective process is in the skin, and it will not advance across scar tissue; it never affects the scar of the operation wound, so that the secret of its arrest seems to be the formation, well outside the area of affected skin, of a line of scar tissue. In the most recent case, reported by H. T. Cox,¹ the nature of the condition was recognised 26 days after the first operation, and the treatment by excision successfully carried out, with complete epithelialisation three months later. The primary operation in this case was for repair of a perforated duodenal ulcer, as it was also in the cases reported by R. Owen-Jones and L. M. Hawksley in 1931,² and by H. J. Nightingale

and E. C. Bowden in 1934.³ F. H. Scotson's case, reported in THE LANCET in 1933,⁴ followed operation for an appendix abscess; and A. M. Stewart-Wallace in 1935⁵ reported a case following drainage of an empyema. The gangrenous process may start around the edge of a sinus at the site of drainage, or around one or more punctures made by deep tension sutures. The sinus itself always heals, and there is an immune island of tissue around the scar. Outside this is the denuded base of the ulcer, possibly with granulations covering it; then a slough of varying extent; the blackish gangrenous edge; and, at the periphery, a red, usually very tender, serpiginous margin, raised and oedematous, and largely undermined.

The cause of the gangrene has given rise to much speculation. One difficulty is that secondary infection may render impossible culture of the original organisms. In Owen-Jones and Hawksley's case long-chained streptococci were found invading the tissue, but the peculiar nature of the microscopical appearances led to them being reported as "corresponding with the appearances of granuloma fungoides." The most usual finding is of a combination of a non-haemolytic streptococcus with a non-specific staphylococcus. Stewart-Wallace gives it as his opinion that the streptococcal infection comes from the serous cavity, and that the particular streptococcus at fault is capable of adaptation to aerobic and non-aerobic conditions. The symbiosis of this organism with a non-specific staphylococcus introduced from without produces the peculiar type of skin reaction. He suggests that cutaneous hypersensitivity may play an important part, and this seems likely from the rarity of the complication.

THE DETECTION OF STRYCHNINE

It is a remarkable fact that no sensitive qualitative test, based on the formation of a well-defined derivative, is available for strychnine. The laborious work of Dr. Douw G. Steyn,¹ veterinary research officer at Onderstepoort, South Africa, on the detection of this alkaloid in carcasses and corpses is, therefore, of considerable interest. Authorities on toxicology differ greatly as to the limiting dilution at which the characteristic bitter taste of strychnine can be detected, some placing it as low as 1 in 700,000 and others as high as 1 in 67,000. In this connexion, Dr. Steyn points out, an hour or more should be allowed to elapse between each test since the taste nerves very soon become exhausted. Even with this precaution he himself was unable to detect strychnine in a solution of 1 in 200,000 when only one drop was placed on the tongue, but he could appreciate the bitter taste of 1 c.cm. of the same solution. The most delicate precipitating agent for strychnine seems to be Wagner's reagent No. 1 (prepared by dissolving 2 g. iodine and 6 g. potassium iodide in 100 ml. of water), which, he found, will give a macroscopic recognisable precipitate with one drop of a 1/20,000 solution of the alkaloid, whilst the next sensitive reagent is Mayer's solution, of which the limit is 1/8000. Steyn appears to consider the well-known Otto test, with bichromate or other oxidising agent and sulphuric acid, to be the most delicate colour test for strychnine, but it is not, in his experience, specific, as he obtained from a decomposed liver which was known not to contain strychnine a positive sulphuric-bichromate test and the solution was

bitter to the taste. In order to express a definite opinion as to the presence or absence of strychnine in purified extracts of specimens of organs, it is essential, in Steyn's view, to conduct the following tests: (a) taste test, (b) colour test, and (c) a biological test. For this latter he prefers immature white mice (about 14 days old) to frogs, on grounds that mice are always obtainable and behave uniformly, whilst the sensitivity of various species of frogs differs and some are not obtainable at all seasons of the year. The stability of strychnine in the bodies of animals which have been killed by this alkaloid is still a matter of discussion. Steyn, using Glaister's method of extraction, which he finds the best, was able to detect it in three carcasses of dogs exhumed 10 weeks after death, but in only one of four dogs exhumed 18 weeks after death, and in only four out of eight which had been buried for 11 months.

TREATMENT OF BACTERIAL MENINGITIS

THE wireless appeal on Feb. 24th to any doctor with a patient recently recovered from infection with Pfeiffer's bacillus met with immediate response. It suggested a confidence that the life of a child suffering from meningitis might be saved by some form of serum therapy or immuno-transfusion which may not be generally shared; but the discovery, usually after repeated examinations of the cerebro-spinal fluid, of the infecting organism in bacterial meningitis naturally brings with it the impulse to try specific therapy. A recent analysis by C. J. Tripoli¹ of all the cases of bacterial meningitis admitted to the State Charity Hospital of Louisiana during the past ten years, many of them being under his personal observation, gives little encouragement to the use of serum in meningitis other than the cerebro-spinal form. The total was 468, and among them meningococcal meningitis heads the list with 221 cases (47 per cent. of the total) and 144 deaths, a case-mortality rate of 65 per cent. There were 111 examples of pneumococcal meningitis (24 per cent.), 90 being untyped, and all save one of these proved fatal. From tuberculous meningitis (51 cases, 11 per cent.) there were no recoveries. The remaining 86 cases included streptococcal and staphylococcal infections of varying strains, mixed infections, and purulent meningitis of unknown causation.

In the treatment of meningococcal meningitis (cerebro-spinal fever) six different methods were employed; serum administration was the basis of five. Simple lumbar drainage was used for 14 patients, all of whom died; but since most of them were moribund on admission, the results are not a true index of the value of the method. Many of the patients (130) suffering from cerebro-spinal fever were treated by repeated intravenous, intramuscular, and intraspinal injections of antimeningococcal serum after withdrawal of "as much spinal fluid as possible." Of this group 87 died (a case-mortality of 67 per cent.). Tripoli points out that with the foregoing methods no attempt is made to maintain the normal spinal fluid pressure, and further it is difficult for the serum to reach the ventricles and particularly the more important subarachnoid spaces. Serum injected intravenously does, it is true, ultimately reach the cerebral ventricles but in a very much diluted form. Therefore, in 54 patients, the intracisternal route was utilised alternately with the intraspinal. Of these patients 26 died (case-mortality 48 per cent.). Tripoli describes a modification of the Lyon²

"substitution" method of serum therapy, by which serum containing phenolphthalein as an indicator is introduced into the ventricle at the same time as cerebro-spinal fluid is being drained by lumbar puncture, the process being stopped when serum appears at the lumbar site. Tripoli places the patient on his side, the head of the table being raised 9 inches. He then introduces a needle into the basal cistern and a second needle into the lumbar cistern, and allows spinal fluid to escape from both needles. The flow from the basal cistern usually ceases first, and as soon as this happens, the lumbar flow continuing, warm serum containing a phthalein indicator is introduced cisternally. The table is then lowered immediately, so that the foot is 6 inches higher than the head, and the serum is allowed to flow into the cistern until it fills the ventricles and appears at the lumbar tap. At the same time, up to 80 c.cm. of serum is given intravenously and up to 100 c.cm. intramuscularly. Of 19 successive cases treated by this method 8 were fatal (case-mortality 42 per cent.), a result which Tripoli, while drawing no definite conclusions, points out is more favourable than those of other methods. He mentions the satisfactory reports upon Ferry's meningococcal antitoxin, but, pending the completion of his own comparative study, expresses no opinion on it.

The methods employed for the treatment of the 247 cases of meningitis other than meningococcal were many and various. Simple lumbar drainage used in 181 cases resulted in 1 recovery, the organism in this case being *Hæmophilus influenzae* (Pfeiffer's bacillus). Intraspinal administration of chemical agents such as mercurochrome proved to be useless in 7 cases; indeed death occurred so quickly in 4 of them that the chemical employed was suspect. For pneumococcal meningitis, specific and non-specific sera and vaccines were without avail; severe reactions "sometimes causing death" are stated to have attended the use of antipneumococcus serum. Permanent and forced drainage of the basal and lumbar cisterns (L. S. Kubie), or surgical drainage of the focus and replacement of the spinal fluid by non-specific serum with and without intracarotid injection of chemical agents were among the heroic methods employed in other cases in Tripoli's series. It is true that in 4 cases of non-meningococcal meningitis treatment by spinal lavage with non-specific serum and the eradication of primary foci of infection was successful; but, on the whole, the results of therapy in forms of meningitis other than cerebro-spinal fever were almost uniformly bad.

SCIENTIFIC SOCIETIES AND RATES

WHILE the de-rating of hospitals is still awaiting the serious attention of Parliament, a recent case at Liverpool is a reminder that scientific societies can sometimes escape assessment. An Act of 1843 exempted non-profit-making societies instituted for the exclusive purpose of science, literature, or the fine arts, and supported wholly or in part by annual voluntary subscriptions. The Liverpool Amateur Photographic Society, founded in 1853, claimed to come within the statutory exemption. It seemed to be wholly or partly supported by voluntary contributions, and it was precluded from making any dividend, gift, or bonus to its members. The society had a distinguished history, and one of its members had invented the dry-plate process. Counsel for the assessment committee replied that the yearly payments of the members could not be regarded as voluntary contributions within the words of the

Act. Photography, he said, might be a science; to some it was a business, to others a hobby; all that the members of the society appeared to do was to congregate for intercourse relating to their common hobby. The Recorder of Liverpool decided against the society. He held it was not instituted exclusively for the purposes of science or the fine arts, nor did the annual subscriptions and occasional gifts of its members amount to "annual voluntary contributions." According to a dictum of Lord Herschell in the case of the Art Union of London in 1896, members' yearly subscriptions, which purchase them an advantage and are not made as a gratuitous offering for the benefit of others, do not comply with the statutory condition that the society should be supported by "annual voluntary contributions." The Act of 1843, be it noticed, speaks of "science or fine arts." The Royal College of Music obtained exemption from rates in 1898, music being one of the fine arts. The Institution of Civil Engineers had earlier been refused exemption. A professional art, it seems, is not a fine art.

A PLEA FOR COÖRDINATED TOWN PLANNING

THE National Housing Committee, a voluntary band of nine public-spirited men who are working under the chairmanship of Lord Amulree, had already published two important constructive reports¹ before the Housing Act of 1935 came into force. In a further interim report, they point out that this Act marks a definite stage in the evolution of national housing policy, and that if the Government's anticipations are fully realised, one side of the housing problem—the provision of a very large number of dwellings for overcrowded populations—should be solved in measurable time. It is not enough, however, to provide dwellings; it is at least equally important that these dwellings should be built in the right places and in the right relationship to transport facilities, to places of employment and recreation, and to all the other elements which compose the physical pattern of the country's development. Without an efficient system of town and country planning, the national housing campaign may create as many problems as it solves. The committee give examples of fundamental errors both of distribution and of interrelation in the development of housing (municipal as well as private enterprise), of industries, of road and rail transport, and of public services, in various parts of the country. All will agree that the safety and efficiency of the Great West-road as a long-distance fast-traffic artery has been permanently damaged and its amenities ruined by the failure to restrict and plan its frontage development, and those who have recently driven along the Barnet by-pass road on the London side of Hatfield, near the road to Lemsford, will have been horrified by a mushroom development of similar unplanned type. Local authorities have been invested with considerable powers of control, but the powers are permissive, and there is no national and often no regional master-scheme to guide the planning work of individual authorities. The committee's plea is for machinery through which a policy and a broad master-plan for the physical pattern of national development can be worked out at the centre, and imposed as a controlling background and purpose on local schemes and projects. The machinery must operate continuously, for its plans and policies must be readily adjustable to suit changing circumstances. It must

¹ See THE LANCET, 1934, i., 1123, and ii., 148.

command the highest technical skill and be sufficiently independent to obtain its own information by surveys and investigations, to stimulate and, where necessary, to compel the requisite local action to implement its schemes, and to formulate, for the Government's consideration, such proposals as it thinks necessary for the modification and extension of the planning system. In conclusion the committee stress the intimate connexion between their proposals and the efforts which are being made to bring back prosperity to the distressed areas, holding rightly that a well-planned national housing policy should be an effective weapon in the campaign for their rehabilitation.

LONG SURVIVAL WITH METASTATIC MAMMARY CANCER

THE attitude of the medical profession to mammary cancer is, in general, pessimistic, for though no problem in surgery or pathology has been more diligently studied, at any rate during the last twenty years, little improvement in survival rates can be recorded. It is now accepted that the possibility of cure or at least of considerable prolongation of life is dependent, in the main, on the stage the disease has reached when the patient first presents herself for treatment; local recurrence after operation or the development of metastatic growth is therefore regarded as an ominous, if not more or less hopeless, sign pointing to widespread dissemination. A case recently recorded by M. C. Tod and E. K. Dawson,¹ of survival with maintenance of health for 24 years after operation for mammary cancer, in spite of recurrence and metastases, suggests that a pessimistic outlook is not necessarily justified, and that in some patients there may be an undefined and, at present, undefinable factor of "resistance" which prolongs life in spite of widespread tumour development. The patient in this case, a married woman of 47 years when first treated, developed a local recurrence 12 years after radical operation, and subsequently metastases in the opposite breast and axilla, which were treated by irradiation and excision. Tumour tissue, if still present, is now quiescent, and the general condition of the patient is satisfactory. Though such a long survival is probably very rare it provides an encouragement to clinicians, and also suggests that adequate post-operative irradiation of the primary tumour area might in similar conditions serve to prevent local recurrence and the possibility of further dissemination.

PROSPECTS IN THE INDIAN MEDICAL SERVICE

ALTHOUGH no official pronouncement has yet been made it is now a matter of common knowledge that a considerable number of attractive posts in the Provinces will be reserved for European officers of the Service. The Secretary of State for India has recently given a public assurance that the standard of medical aid by European doctors for European civil officials and their families in India will be maintained. For the purpose of honouring this undertaking, and also of providing a war reserve of European medical officers, it has been found necessary to reserve for European members of the Service a number of specialist clinical posts and civil surgeoncies in the Provinces, in addition to a considerable number of posts in the Foreign and Political department. Apart from the posts which have been specifically reserved for European officers there will also be many clinical, research, and public health

appointments for which all I.M.S. officers will be eligible. It has been asserted indeed by responsible people that the prospects of highly qualified recruits to the Service have never been better than they are at present. Although some of the prize appointments will be open only to men with special qualifications there will be excellent prospects of attractive careers both in military and civil employment for men of good all-round attainments. In view of the number of recruits likely to offer themselves after an official announcement young graduates who are thinking about going to India may be well advised to lose no time in making inquiries about the conditions of life and work in the I.M.S. An important point which has been overlooked by many candidates for commissions in the military services is that permanent commissions are given at the outset to all who join the I.M.S., so that unless the officer himself prefers to retire with a gratuity after a few years he automatically retains his commission, instead of finding himself in the position of an applicant for a permanent commission after several years of temporary service. We are informed that in the other military medical services less than half of those who obtain temporary commissions are likely to be retained after their first contract has expired. Many young graduates have entered the I.M.S. with the intention of taking the gratuity for which they become eligible after six years, but few exercise their right to retire; this fact speaks for itself. In the column containing details concerning the Services information is given as to application for commissions.

At the Royal College of Physicians of London on Thursday, March 5th, at 5 P.M., Dr. R. A. McCance will deliver the first of his Goulstonian lectures on medical problems in mineral metabolism. His second and third lectures will be given on March 10th and 12th.

Dr. R. Kuczynski, formerly director of the statistical office, Berlin-Schönberg, is giving three lectures at University College, London, on March 3rd, 6th, and 10th, at 5.30 P.M. His subject will be Recent Population Trends, and Lord Dawson will take the chair at the first lecture.

King Edward's Hospital Fund for London have issued a revised edition of their pamphlet which gives particulars of the provision made for the professional and middle classes at voluntary hospitals in London. This shows a substantial increase in the number of beds for paying patients, as compared with the accommodation available in 1928, when a special committee of the King's Fund inquired into the situation. The total number is now 1997 at 108 hospitals. It should be emphasised that the increase in the number of pay-beds is in addition to an extension of the accommodation for patients in the ordinary wards of the hospitals. This pamphlet gives full particulars of the charges at each individual hospital, and copies may be had from Messrs. Geo. Barber and Son Ltd., Furnival-street, E.C. 4, price 3d., post free.

CONGRESS ON FEVER THERAPY.—As already announced, the first International Congress on Fever Therapy will be held in New York City from Sept. 29th to Oct. 3rd. It is suggested that an English committee should be formed to collect reports which have appeared in this country, and all those who have information which they wish to be brought forward in New York are invited to write to the medical secretary, the International Clinic, Sherwood Park, Tunbridge Wells.

PROGNOSIS

A Series of Signed Articles contributed by invitation

XC.—PROGNOSIS OF CONGENITAL SYPHILIS

In discussing the prognosis of congenital syphilis it is necessary to consider (a) the outlook for an affected patient, and (b) the history and course of the disease itself.

Outlook for an Affected Patient

This depends upon several factors: (a) the severity of the disease; (b) the age of the patient when the disease is first diagnosed and adequately treated; and (c) the adequacy of the treatment given.

SEVERITY OF THE DISEASE

As a general rule the more recent the infection in an untreated mother the more severe is the infection in the infant, and occasionally an infant is born so heavily infected suffering, for example, from syphilitic pemphigus or syphilitic nephritis that it dies within a few days or weeks of birth, in spite of the best nursing and antisyphilitic treatment one may give it. If, as is usually the case, the infant is born apparently healthy, and shows signs of the disease during the first four or five weeks of life, even though the rash be extensive and severe and be accompanied by much nasal catarrh with consequent snuffles, life can usually be saved by appropriate treatment and good nursing. In my experience, the nursing is of importance, as great as, if not greater than, the antisyphilitic treatment itself. If the infant's strength is to be maintained for example adequate nourishment is essential. A syphilitic baby whose nasal passages are blocked with discharge from a diseased mucous membrane is unable to take its feed either from the breast or from a bottle. The toilet of the nose and mouth should be rigorously attended to before the feeding is started by wiping away all mucus with moistened swabs of cotton-wool, and the utmost patience is needed in feeding. It may take as long as two hours to get the baby to take a feed of two ounces, but recovery may depend upon perseverance in this respect. Since constant attention to the rash on the body and face is also essential, it can be readily seen how a bad case of congenital syphilis may occupy a nurse's whole time for several weeks. I have had several little patients with disease of such severity (one or two of them with oedema from nephritis) as to make the prognosis seem almost hopeless who nevertheless made a good recovery and appeared to be well several years later.

At the present time severe cases of congenital syphilis seem to be less common than they used to be. This may be due to a natural diminution in the pathogenicity of the spirochete and/or to the effect of a certain amount of treatment of the parents. The symptoms may be vague and inconclusive, such as malnutrition, pylorospasm, anaemia, and so forth, and the infant who fails to respond to ordinary treatment may at once improve and eventually be cured if the presence of syphilis is suspected and confirmed, and treatment is pursued vigorously.

AGE OF THE PATIENT WHEN THE DISEASE IS FIRST DIAGNOSED

This factor is of prime importance in prognosis. Provided that an infant is not overwhelmingly infected by the spirochete, adequate treatment started during the first three to six months of extra-uterine life and given over a sufficiently long period

will result in a complete cure in almost all cases. This statement, however, raises questions to which different paediatricians and syphilologists will give varying replies; notably (a) what is adequate treatment? (b) How long should treatment be continued? (c) What criterion of cure should be adopted?

(a) *What is adequate treatment?*—Certainly the time-honoured treatment with mercury cannot be relied upon for a cure except perhaps of an occasional very mild infection in a child whose father had contracted the disease many years previously and had had some treatment for it. I have seen a few cases of this kind. The recognised treatment to-day is injections of arsenicals together with mercury (by mouth or inunction) or injections of bismuth. Some authorities rely on bismuth alone. In many German clinics congenital syphilis is being treated solely by the oral administration of spirocid (stovarsol, orarsan, acetarsone) with, it is claimed, successful results.

(b) *About the duration of treatment* no stereotyped rule can be given though certain general principles may be followed. Some authorities give at least two years' treatment; Tytler Burke recommends five years' treatment which is in my view unnecessary as a routine, and must prove difficult to apply in practice. So long a course of treatment must imply a number of defaulters. On account of the possible psychic effect of the weekly visits to the clinic and of the discomfort or pain associated with the injections—and it is remarkable how even young infants seem to remember their previous experiences directly they come into the injection room—I decided at one time to curtail treatment as much as possible, and gave one complete course of eight arsenic injections after the Wassermann reaction had become negative. This seemed to be satisfactory in some cases, but in others there was a serological relapse and further treatment had to be given; so my present practice is to treat for at least two years, with intervals of one month between the courses, provided the Wassermann reaction in blood and spinal fluid is negative during the whole of the second year and there are no symptoms of the disease. If the Wassermann reaction and flocculation tests are positive, treatment should be continued through a third and if necessary a fourth year.

(c) *The criterion of "cure."*—A negative blood test and a normal cerebro-spinal fluid together with absence of all clinical manifestations of active syphilis for a period of years is to be aimed at, and can usually be attained in the case of infants who have been adequately treated. In older children, who first come under observation and treatment at the age of, say, five to ten years, the prognosis is not so good, because even although the blood serology may have proved satisfactory, there is no guarantee that later manifestations of the disease may not arise. I have seen interstitial keratitis in children whose blood Wassermann had been negative for four and six years and who had shown no sign of active disease at any of their annual examinations since the Wassermann test was first found to be negative. Some authorities go so far as to say that congenital syphilis in older children can never be regarded as cured. Personally I think this extreme view is too pessimistic, but a follow-up for at least ten years and preferably until adult age is certainly desirable. This often proves a difficult matter, and necessitates in institutions an efficient social service organisation.

ADEQUACY OF THE TREATMENT GIVEN

A young child who shows only a mild infection because the disease in the parents is not recently acquired or because the mother had some treatment during pregnancy will probably be cured after one year's thorough treatment. Older children, provided they have no gross vascular or organic lesion of the central nervous system, appear to make a good recovery with adequate treatment, but this may have to extend over four or more years and necessitate the giving of 15 to 20 grammes of arsenicals in forty or fifty injections as well as malaria therapy in Wassermann-fast and positive cerebro-spinal fluid cases. The most tragic cases are those of congenital neuro-syphilis which are not diagnosed until an encephalitis or a hemiplegia draws attention to the patient's condition. The prognosis in such cases is often hopeless as regards life; there is progressive mental deterioration involving a stay in a mental hospital for several years where life may be prolonged by treatment, though there is no question as to the outcome of the disease. Children with a syphilitic hemiplegia will be permanently disabled, though if the blood and spinal fluid can be rendered permanently negative, their lives may be saved.

Special manifestations of congenital syphilis, such as periostitis of the long bones, interstitial keratitis, gummatous lesions of the skin or mucous membranes, hæmoglobinuria, and anæmia, respond readily to prompt antisyphilitic treatment, but the ultimate prognosis as regards cure will depend upon the factors already considered.

History and Course of the Disease

Although in the eighteenth and nineteenth centuries a few physicians recommended the antenatal treatment of expectant syphilitic mothers to protect the child, it was not until the discovery of "606" by Ehrlich and Hata in 1909 that the prevention of congenital syphilis was seriously considered. Since that time an ever-increasing volume of evidence has been accumulated to show that adequate treatment of the expectant mother will fully protect her child in a very large percentage of cases, as high as 95 per cent. according to N. R. Ingraham (*Amer. Jour. Syph. and Neurology*, October, 1935, p. 556), and even if the infant shows signs of congenital syphilis early and appropriate treatment will cure it.

Knowing as we do how difficult some cases of the disease are to diagnose, and also that in older children a "cure" may take four or more years to attain, it behoves us to take all possible steps to prevent the disease. Women who receive treatment at the ordinary clinics should be warned to apply for further treatment as soon as they realise that they have become pregnant. All women attending antenatal clinics should have a Wassermann test, and if found positive, should be treated by injection. In my view the ideal to be aimed at is a blood test for every pregnant woman; if it were realised that this was the usual practice, no difficulties would arise. Congenital syphilis would be almost non-existent after the lapse of a generation; many stillbirths would be prevented; many children who are now doomed to die young, after some years of miserable existence in mental homes, and others who perforce lead incomplete lives owing to physical disabilities, would be spared to live useful lives.

DAVID NABARRO, M.D., F.R.C.P.,

Director of the Pathological Department and Medical Officer in Charge of the Venereal Diseases Clinic, Hospital for Sick Children, Great Ormond-street.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Capt. Sheldon F. Dudley, O.B.E., M.D., F.R.C.P., to rank of Surg. Rear-Admiral in the vacancy caused by the retirement of Surg. Rear-Admiral J. S. Dudding, C.B., O.B.E., on relinquishing command of the R.N. Hospital, Plymouth.

Surg. Rear-Admiral Dudley, at the age of 52, has been 30 years in the Royal Navy, having been appointed Surg. Lieut. Commander in 1914, and Surg. Captain in 1929. In *THE LANCET* of May 11th, 1935, we noted his appointment as Deputy Director-General.

Surg. Lt.-Comdrs. H. J. McCann to *Bee*, and E. B. Pollard and J. C. Souter to rank of Surg. Comdr.

ROYAL NAVAL VOLUNTEER SERVICE

Surg. Lt.-Comdr. R. J. Matthews to *Royal Sovereign*.
Proby. Surg. Lt. R. W. G. Lancashire to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS

Short Serv. Commissions: Lt. (on prob.) J. McN. Lockie is restd. to the estab.

Among the results announced of the examination (in written subjects) of officers with a view to promotion in the Regular Army and Indian Army, which was held in India and Burma in October last, are the following successful candidates: Major W. A. D. Drummond, Capt. D. Bluett, and Capt. R. J. G. Hyde.

The War Office announces that applications are invited from medical men for appointments to commissions in the Royal Army Medical Corps. Candidates will be selected for commissions without competitive examination and will be required to present themselves in London for interview and physical examination on or about April 23rd next. Further information may be seen in the advertisement which appeared in *THE LANCET* last week (p. 52), and full particulars may be obtained on application to the Assistant Director-General, Army Medical Services, The War Office, London, S.W.1.

REGULAR ARMY RESERVE OF OFFICERS

Capt. F. W. Oldershaw resigns his commn.

TERRITORIAL ARMY

Lt.-Col. J. L. Hamilton, M.C., T.D., to be Bt.-Col. and vacates comd. of 167th Fd. Amb.

Lt.-Col. W. A. Lethem, M.C., to be comd. 167th Fd. Amb.

Maj. A. C. Haddow, T.D., to be Lt.-Col.

supernumerary for service with O.T.C.: Maj. R. B. Green (empld. Durham Univ. Contgt. (Med. Unit), Sen. Div., O.T.C.) resigns his commn. and retains his rank, with permission to wear the prescribed uniform.

Capt. A. T. Fripp resigns his commn.

Lts. H. F. Apthorpe-Webb, R. I. Hyder, E. C. Murphy, and F. V. Allen to be Capt.

F. N. N. Roberts (late Flight-Lt. R.A.F.) to be Lt.

Lt. M. Ellis resigns his commn.

ROYAL AIR FORCE

RESERVE OF OFFICERS

Special Reserve: C. W. Kidd is granted a commission as Flying Officer.

INDIAN MEDICAL SERVICE

Lord Linlithgow, Viceroy-Designate of India, has appointed Major H. H. Elliot, M.B.E., M.C., F.R.C.S. Edin., I.M.S., to his personal staff.

The promotion to the rank of Maj. of the undermentioned officers is confirmed: A. Tait, G. P. F. Bowers, J. S. Riddle, J. E. Grey, S. Smyth, M. H. Wace, R. L. Frost, J. C. Drummond, D. MacD. Fraser, J. F. Shepherd, K. S. Fitch, and S. C. H. Worseldine.

J. M. F. Byrnes and W. J. Young to be Lts. (on prob.).

There will be a selection of recruits early in April and thereafter at intervals of about three months. A memorandum of conditions of service can be obtained from the secretary, Military Department, India Office, Whitehall, London, S.W.1, and any who are interested in the matter should consult personal friends who are actually serving in the Indian Medical Service or apply for an interview with the medical adviser, India Office, Whitehall, London, S.W.1.

SPECIAL ARTICLES

PAYING PATIENTS IN HOSPITALS PROBLEM OF GLOUCESTERSHIRE ROYAL INFIRMARY

A SPECIAL meeting of the governors of the Gloucestershire Royal Infirmary was called a week or two ago to consider the conflicting interests of the workpeople's contribution scheme and the medical staff. After a long discussion the following resolution, proposed by the chairman, Mr. Stamford Hutton, was adopted by 29 votes to 24:—

That it be an instruction to the weekly board to investigate the best means of meeting the wishes of the medical staff with regard to (1) the limitation of persons attending as out-patients to those whose means are insufficient to enable them to obtain as private patients the advice and treatment required; (2) the setting up in connexion with the Infirmary of paying wards freed of any restrictions as to income—and to report thereon to the general committee.

Speaking to this resolution, Mr. Hutton said that, while on the one hand the honorary medical staff had good grounds for complaint about hospital abuse, the committee in charge of the contributory scheme had an idea that the medical staff were seeking to exploit this scheme in their own interests. The staff were convinced that stricter supervision was needed in order to prevent members of the scheme from getting free treatment in the out-patient department when they could afford to go to private doctors. This was an accepted principle of the hospital; request was set out in the printed annual report that the hospital subscriber should inform himself of the circumstances of the patient whom he recommended for admission. No contributory scheme should be allowed to alter the basis upon which the institution was run—namely, for those who had not the ability to pay for their cure. While the hospital authorities did not make any charge for treatment they were entitled to recover overhead expenses. The medical staff contended, and Mr. Hutton said he agreed with them, that some limit ought to be placed upon the income of the contributors. This was done at other institutions of the kind. On inquiry he found that of 50 hospitals with a similar scheme in 33 there was an income limit of £5 per week; 44 of the 50 made some inquiry into the means of contributors who applied for hospital care. The abuse of the out-patient department was, Mr. Hutton added, not restricted to contributors of the scheme. Turning to the question of paying wards, admission of private patients to these was limited to those with incomes below £400 for a single man or woman, below £500 where there was a family. The medical staff asked to have the income limit done away with. Again, from inquiries he had made he was in a position to state that 39 of 53 hospitals in the provinces admitted private patients irrespective of their financial position. They had been reminded that the Infirmary had a waiting-list of 116; this was a matter for regret, but he felt sure that no reasonable increase in the number of beds would diminish this list because the hospital spirit had become so prevalent among those who wanted to go into the ordinary wards that without a close scrutiny of income they would never be able to keep within the limits. Unless they abolished the income limit for paying patients Mr. Hutton felt they were not making medical practice sufficiently attractive to induce the best class of medical men to settle in the

district, and the standard would go down. Hospitals were getting more and more expensive and delicate machinery and appliances which required men who had been trained to use them. When the paying wards were set up in 1925 it was hoped that they would not interfere with nursing-homes, but that hope had not been verified.

In his reply, Mr. W. C. Oxenham, chairman of the workpeople's hospital committee, said there was some reason for the appointment of an almoner to see that consultations were not obtained by people who could afford to pay, but he was doubtful whether the doctors should receive a percentage of the contributions of the workpeople, at all events not 25 per cent., and he doubted whether the paying wards had seriously diminished the doctors' incomes, as examination of the figures showed that last year they received some 60 per cent. of the income from the wards. If the doctors were permitted to charge what fees they liked, could anyone, he said, see people of moderate means ever getting into the wards? The provision of nursing-homes for people with affluent means was still a business proposition.

Speaking on behalf of the honorary medical staff, Dr. A. Alcock said that in his time the number of beds at the hospital had increased from 80 to something like 200, which meant a great deal more work for the staff, and it could not be seriously contended that this big increase came from people who were destitute of means to pay. Times were surely not as bad as that. There was no doubt that the doctors' private practice had declined because of the workpeople's contribution scheme. Is it fair or right, he said, to expect the doctor to treat for nothing a man earning £5 a week? Nursing-homes certainly were now not business enterprises.

After a lively discussion in which it was stated that, if the doctors' proposals were accepted, collectors for the hospital scheme would be in an embarrassing position and scores of people would stop contributing, the chairman's resolution was adopted.

MEDICINE AND THE LAW

Alleged Negligence in Hypodermic Injection

THE Privy Council dismissed the appeal of a doctor last week in *Caldeira v. Gray*, where the Supreme Court of Trinidad, after a hearing which lasted several weeks, had awarded the patient £864 3s. 4d. damages for negligent treatment. The negligence was alleged to have occurred in hypodermic injections of quinine in the right buttock. It was said that the needle had been so unskillfully inserted as to injure the sciatic nerve. The plaintiff complained that, immediately after he got up from the bed on which he lay while the injection was made, he walked with a dropped right foot, and that the disability had continued ever since. There was a great volume of medical evidence taken in the Trinidad Court; it had been exhaustively analysed by the trial judge and the Privy Council did not attempt to go through it all again. Each side had given its own explanation of the injury. The patient said that either the needle pierced the sciatic nerve or else the injection was made so close to the nerve that the quinine permeated into the nerve; he had no symptoms of foot-drop before the injection. The trial judge accepted this explanation, observing that it was fair to infer that the injection caused, or

contributed to, the foot-drop. The doctor explained the injury by saying that the patient had suffered from latent alcoholic neuritis before the injection and that the alcoholic toxins in the patient's system were lit up and precipitated by the shock of the injection. There was, however, no definite evidence of the existence of the latent alcoholic neuritis; the patient was willing to confess that he enjoyed an occasional "spree," but no witness put the case for alcoholism any higher than that. The medical witnesses who gave evidence on behalf of the doctor during the Trinidad hearing could claim no actual experience of latent alcoholic neuritis precipitated by shock; they agreed that such a condition was rare and they were unable to cite a single authentic case which lent full support to the theory. Thus the defendant doctor's explanation could be described by the trial judge and by the appellate tribunal as resting on mere speculation. It presupposed alcoholism in the patient and it required the concurrent existence of two conditions—namely, the existence of latent alcoholic neuritis and the flaring up of the neuritis upon so slight a shock as the injection would cause. The Privy Council considered that the concurrence of these two conditions was, on the evidence, highly improbable. It was argued for the doctor that an experienced practitioner could not have made the cardinal and elementary blunder attributed to him by the patient. Lord Alness, who delivered the judgment of the Privy Council, recalled that there were many instances of signalmen and engine-drivers of experience who on occasion neglected their duty. Their lapses illustrated the principle that familiarity might breed contempt and that an ordinary practice sometimes lacked the constant care which the circumstances demanded. Be that as it may, the judgment declared that the patient's explanation of his disability, supported by the medical evidence which he adduced, had not been displaced by evidence on the other side. The case for the plaintiff was clear, simple, and straightforward; the case for the defendant doctor was speculative, theoretic, and unconvincing.

Although the Privy Council thus tended to express its own opinion upon the merits of the claim, the appeal was not a re-trial. The Trinidad Court had carefully and dispassionately weighed the two conflicting theories and had reached a clear conclusion of fact in favour of the patient. It is not the practice of the Judicial Committee of the Privy Council to reverse a conclusion of fact based upon adequate evidence. The principle is the same as that which was decisive not long ago in the House of Lords case of *Powell v. Streatham Nursing Home*. The trial court has an overwhelming advantage over the appellate tribunals in that it has seen and heard the parties and their witnesses.

Professional Libel Action Settled

Dr. A. M. Simpson's libel action, claiming damages against the eight doctors constituting the medical committee of St. Paul's Hospital, Endell-street, W.C., and a subcommittee of one of the departments of the hospital, was settled in Mr. Justice Macnaghten's court last week. The plaintiff, for many years honorary surgeon at the hospital, had attended before a subcommittee set up by the committee of management to inquire into part of the hospital's work. His comments and criticisms at this inquiry became known to other members of the staff. The defendants drew up replies to his criticisms before the committee had made any report. These replies imputed personal motives to the plaintiff. The

combination of his critics and the publication of the statements about his motives resulted in his not being re-elected to the position of senior surgeon of the hospital. Such was the account given by his counsel, Sir Patrick Hastings, in announcing the settlement of the case and the withdrawal of all imputations. Mr. Norman Birkett, for the defendants, handsomely agreed with what had been said, and the judge pronounced his benediction. If there must be libel actions between professional men, the best kind of libel action is one which is happily settled before witnesses are called. It is profitable to the bar if, when once briefs have been delivered, the presentment of the case in court can be concluded in a few minutes and in the easy atmosphere of mutual compliments. Would it not be profitable to the medical profession if there were some earlier method of composing differences with less expense and less publicity?

AUSTRALASIA

(FROM OUR OWN CORRESPONDENT)

POST-GRADUATE WORK IN NEW SOUTH WALES

IMPORTANT changes have taken place during the last few months in the organisation of post-graduate work in New South Wales. Occasional courses for graduates have been held in Sydney since 1900 by the University and by the New South Wales branch of the British Medical Association, which provided teaching and instruction for its members by means of lectures and clinical meetings. In Victoria, a lead had been given by the appointment of the Melbourne Permanent Post-Graduate Committee, and in 1929 the New South Wales branch formed a standing committee of its council for the purpose of organising post-graduate work in New South Wales. This standing committee showed that wider representation and scope and the complete control of its own funds was important for the proper carrying out of its function. Accordingly, in September, 1932, the branch founded an autonomous body which was known as the New South Wales Permanent Post-Graduate Committee. Under this committee, considerable advance was made and post-graduate instruction in medicine began to become regular and definite. After three years' working it became apparent that still wider scope was required and that a close association with Sydney University was essential. After several conferences had taken place with the University, the senate, on Oct. 10th, 1935, adopted a new by-law which had been approved by the Governor, and the Executive Council, establishing a committee to be known as the New South Wales Post-graduate Committee in Medicine, and on Nov. 4th, 1935, the members of this new committee were appointed. The old committee went out of existence on Nov. 30th, 1935, and all its funds and functions, including any matter which that committee had undertaken or authorised, taken over by the new committee. The by-law of the University that constitutes this body provides for a fund for the promotion of post-graduate education, study, work, and research, and for the advancement of the art and science of medicine. The Committee consists of the chancellor, the deputy-chancellor, the vice-chancellor, and the dean of the faculty of medicine as ex-officio members, representative members appointed from the faculty of medicine, two from the New South Wales branch of the British Medical Association, and from the honorary medical staffs of a number of metropolitan

hospitals. Except for the ex-officio members or a member representative of the faculty of medicine, no person can be a member of the Committee unless he is a member of the British Medical Association, and all must be active members of the body which they represent.

After a review of the hospital position in Sydney, the Permanent Post-graduate Committee, during its last months, approached the Minister for Health in Sydney with a request that special accommodation should be provided for graduate teaching in Sydney. As a result of this, the Government has decided to reconstitute the Prince Henry Hospital, Sydney, as a post-graduate hospital. This hospital, which will have 1100 beds, has hitherto been completely under government control. This will cease and the board will be controlled by a committee consisting of a number of business and medical men, on which it is proposed to give representation to the University of Sydney, the Royal Australasian College of Surgeons, the Association of Physicians, and the New South Wales Government. A Bill for this purpose will be brought forward shortly by the Minister for Health.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE ROYAL MEDICAL SOCIETY

Dr. S. A. Kinnier Wilson was the guest of the evening at the annual dinner of the Royal Medical Society which was held in the hall of the Royal College of Surgeons of Edinburgh last week. Dr. A. M. McFarlan, the senior president, presided over a company of about 120, and the other presidents were Dr. H. M. Adam, Dr. A. F. Barron, and Dr. R. T. Campbell.

In proposing the toast of the guest of the evening, the chairman welcomed Dr. Kinnier Wilson as a former president of the society and paid a tribute to his many contributions to neurology. Dr. Kinnier Wilson, in his reply, said he would like to pass on a few lessons he had learned in the 33 years that had elapsed since he had occupied the presidential chair. One was "Never show surprise"; another, "Never say the same thing twice to a patient"; a third piece of advice he offered was, "Never believe what the patient says the doctor said"; and a fourth, "Be decisive in your indecision." If doctors did not know what a disease was they should know exactly what their reasons were for not knowing. A further piece of advice was: "Never take a meal with your patients." In proposing the toast of the Royal Medical Society, Dr. Wilson said that it was at the society's meetings that he first learned to stand on his feet, to face criticism, and to think medically; it was there that he got his first glimpse of the real medical world. The society had a marvellous history of nearly 200 years; it was old, but ever new, as it was conducted by generations of new men every year. Those who had been active members in the past were proud to think that they were once part of that great wave, sweeping onwards.

Dr. H. M. Adam, who replied to the toast, referred to the preparations which are being made for the celebration of the society's bicentenary next year. The bicentenary fund now amounts to £1500, and the Royal Colleges have demonstrated their friendship to the society by their generous contributions. He thanked the College of Surgeons for allowing the society to hold their dinner in the college hall, and drew attention to the fact that on one occasion, over a hundred years ago, the hall of the College of

Surgeons was in such a dilapidated state that the members of the College were glad to have permission to use the hall of the Royal Medical Society.

NEW GLASGOW CLINIC

The Lansdowne Clinic for Functional Nervous Disorders at 400, Great Western-road, Glasgow, was inaugurated at a meeting held last week. The clinic is under the management of the directors of the Royal Mental Hospital and its function is to supplement the work carried out by the psychiatric clinics already working in Glasgow. Patients will be seen at the new out-patient clinic, by appointment, only on request of their family physician, for consultation or treatment, and will be allocated to a member of the medical staff who will arrange for any subsequent interviews that may be required, and who will have charge of the case throughout in co-operation with the family physician. It is hoped that the clinic will gradually develop into something much larger to meet the great need for the treatment of minor nervous disorders. Prof. D. K. Henderson, of Edinburgh University, emphasised the value of clinics such as these. He thought it would have a large social and economic value and should do much to relieve those who are nervously ill. Their chief work was preventive and it would often enable the breadwinner of a family to carry on his daily occupation with the aid of the treatment he received.

IRELAND

(FROM OUR OWN CORRESPONDENT)

THE IRISH FREE STATE MEDICAL UNION

The first meeting of the central council of the Irish Free State Medical Union was held in Dublin on Feb. 20th, with Prof. T. G. Moorhead in the chair. The chief business of the meeting was to sign the memorandum and articles of association of the Union, and for the signatories to constitute themselves the central council. According to the articles such of the subscribers to the memorandum as shall be members of the council of the Irish Medical Association or of the Irish committee of the British Medical Association, resident in the Irish Free State at the date of registration of the Union as a company, shall form the first central council. Such council will hold office until the termination of the annual general meeting of the Union to be held in 1936, and its members will be eligible for re-election. There were about thirty members present, and after the signing of the memorandum and articles a general discussion took place on the steps to be taken to render the Union effective. Dr. John P. Shanley was appointed hon. secretary of the Union and Mr. C. MacAuley and Dr. Robert J. Rowlette were elected joint hon. treasurers.

A NEW FEVER HOSPITAL FOR DUBLIN

It has been generally known for some time that the Hospitals Commission favoured the establishment of a new hospital for infectious diseases in or near Dublin, in which the existing Cork-street Fever Hospital would be merged. The recommendation of the Commission has been approved by the Minister for Local Government and Public Health, who last week introduced in the Dáil a Bill for the purpose of establishing such a hospital. It is proposed that the board of the hospital shall consist of 20 persons, of whom 7 shall be elected by the corporation of the city of Dublin, 3 by the Dublin board of public health, 7 by the existing trustees of Cork-street Fever Hospital (and their successors, provision being

made for a continuing electorate), and 3 to be appointed by the Minister. It shall be the duty of the hospital to receive, as far as accommodation permits, any patients suffering from infectious diseases sent on the order of the medical officers of health for the city and for the county of Dublin, their assistants, or any dispensary medical officer in the city or county of Dublin. Provision is made that the corporation of Dublin and the board of health shall make payments to the hospital board in respect of city and county patients respectively. Moreover, the corporation and the board of health shall make good any deficiencies in the establishment account of the hospital from time to time, their

contributions being in proportion to the respective valuations of the city and the county of Dublin. The hospital board, when constituted, is, with all convenient speed, to prepare and submit to the Minister a scheme for the erection and establishment of a new fever hospital in or near Dublin, setting out the proposed site, the plans and specifications, and the estimated cost. Approval of the scheme lies with the Minister who also reserves the right to modify the scheme subsequent to approval. It is understood that the cost of building and equipping the hospital will be met by a grant by the Minister under Section 25 of the Public Hospitals Act, 1933, from the Sweepstake Funds.

PUBLIC HEALTH

THE SPECIAL AREAS

THE report of the Commissioner for the Special Areas¹ deals primarily with economic conditions but merits consideration from its reference to certain aspects of public health.

At the time of the crisis in the cotton trade in Lancashire during the American Civil War public money was found for and employment provided in schemes of sanitary improvement under a special Act—the Public Works (Manufacturing Districts) Act, 1863. To such works many of the Lancashire towns owe a definite impetus towards the amelioration of the appalling sanitary environment which then prevailed. It is of interest to note the repetition of this experience during the present distress, and that the Commissioner has under his powers approved 152 grants to local authorities for works of public utility totalling a sum of £1,870,872. Grants are mostly in respect of sewerage and water schemes but have also been made to maternity and child welfare centres, and as an illustration of recent trend it is significant to remark the emergence of hospital grants—e.g., £240,000 to Durham county council and £250,000 to Glamorgan county council towards the provision of new general hospitals. The assistance thus rendered is timely in view of the fact that the authorities in the special areas are confronted with the difficulty that while schemes for amelioration of public services may be urgent, the pressure of unemployment has both reduced the rateable value and increased demands on the authority, as by the much enlarged scope of public assistance; thus in County Durham in 1934 (estimated population 914,500) a penny rate produced £12,092, in Middlesex (estimated population 1,810,200) the produce was £67,788.

Food for thought is provided by the observations of the Commissioner on the outlook for the adolescent population: "probably the most serious problem of the Special Areas is that presented by unemployment among young men between 18 and 21." Stress is laid on the social aspect of the passing into manhood of youths debarred from useful occupation, living in an atmosphere of unemployment, and accustomed from early years to maintenance by the State. The population of this age-group is given as 11,000, of whom 7000 have been unemployed for more than three months, so that during the recent black years in these areas a multitude has passed forward handicapped by this depressing passage from youth to manhood. The Commissioner shows concern, however, not only with this moral, social, and psychological reaction but also with the physical

condition of this section of the community. He states "the percentage of rejections on medical grounds for juvenile transfer centres and for the men's instructional centres is alarmingly high." Reference to this question is to be found in the recent annual report on "The Health of the School Child," and in the report by the Ministry of Health on conditions in Sunderland and the adjacent areas which stated "the condition of adolescent youths especially those aged 14 and 15 years is the least satisfactory feature of our findings." Anyone acquainted with the special areas must be seriously concerned by the problem of the unemployed adolescent.

It is well that the Commissioner can report some encouraging features, and it is to be hoped that the return of these areas to brighter conditions may not be indefinitely delayed. Limbs from which the blood-supply is cut off cannot but react on the body corporate.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 15TH, 1936

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2173; diphtheria, 1203; enteric fever, 16; acute pneumönia (primary or influenzal), 1308; puerperal fever, 34; puerperal pyrexia, 99; cerebro-spinal fever, 22; acute poliomyelitis, 2; acute polio-encephalitis, 1; encephalitis lethargica, 4; continued fever, 1 (Rugby R.D.); dysentery, 42; ophthalmia neonatorum, 79. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Feb. 21st was 4617, which included: Scarlet fever, 987; diphtheria, 1094; measles, 1194; whooping-cough, 693; puerperal fever, 22 mothers (plus 15 babies); encephalitis lethargica, 281; poliomyelitis, 3. At St. Margaret's Hospital there were 22 babies (plus 11 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (1) from enteric fever, 58 (8) from measles, 5 (1) from scarlet fever, 41 (13) from whooping-cough, 48 (7) from diphtheria, 47 (8) from diarrhoea and enteritis under two years, and 97 (12) from influenza. The figures in parentheses are those for London itself.

The mortality from influenza remains much the same, the total deaths for the last 11 weeks (working backwards) being 97, 85, 98, 104, 89, 110, 110, 80, 67, 62, 45. The deaths this week are scattered over 52 great towns, Birmingham reporting 6, Portsmouth and Salford each 4, Willesden, Oxford, Bradford, Liverpool, Manchester, Rochdale, and Wallasey each 3; no other great town more than 2. Liverpool and Manchester each had 10 deaths from measles, Middlesbrough 4, Croydon, Salford, Sheffield, Warrington, and Bristol each 3. Whooping-cough caused 4 deaths at Birmingham, 3 each at Manchester and Salford. Deaths from diphtheria were reported from 27 great towns: 4 from Liverpool, 3 each from Hull, West Hartlepool, and Plymouth.

The number of stillbirths notified during the week was 253 (corresponding to a rate of 40 per 1000 total births), including 38 in London.

CORRESPONDENCE

ARTIFICIAL RESPIRATION FOR THREE AND A HALF YEARS

To the Editor of THE LANCET

SIR,—I described an unusual case of prolonged artificial respiration in your issue of April 14th, 1934, and I have now to report that the patient, a man who suffered from progressive muscular atrophy, died a few days ago at the age of 66. It may be recalled that respiratory paralysis began in 1932, and was at first intermittent, but continuous artificial respiration became necessary from June, 1932, until his death. An unorthodox manual method was in use for many months before Sir William Bragg introduced a very successful device, using simple apparatus and the experimental method. Eventually a machine worked by the water-supply was specially designed and made by Mr. R. W. Paul. The first instrument was installed in October, 1933. An improved model was substituted a month or so later, and this was in use thereafter. One slight alteration in design was made in October, 1934, in order to improve the lubrication, but no fundamental change or repair became necessary, in spite of the continuous wear caused by the 700 gallons of water which each day passed through it. Fortunately there was no shortage of water in the district during the last two dry summers. On one occasion the water-supply was cut off without notice, on account of repairs to the main; and once the water-pipes froze. The original manual method was used in both emergencies, and the patient was never left alone for fear of such accidents. An alarm note, resembling that of a bird, could be uttered by the patient with tongue and teeth without breath, and it was arranged that this should be a danger-signal to be used if the machine stopped working and the attendant did not notice.

The medical history after 1934 was almost as eventless as the scientific. No new symptoms arose until near the end, and the slight difficulty in swallowing became less. Dr. W. T. Mills, who was in charge of the case, and to whom I am indebted for the clinical details, treated occasional difficulty due to collections of mucus in the respiratory passages with atropine, and two respiratory infections with injections of "pneumococcus immunogen combined." Great care was taken with the skin, and no bedsores developed, in spite of the fact that the patient was moved very little, because there was only one position in which he was really comfortable. During the daily washing, which took 1½–2 hours, the manual method of artificial respiration was employed, which gave the chest a relief from the wearing of the belt. The patient remained mentally active to the last, and both apparatus and illness ran so smooth a course that the chief feature of the case became an unforgettable revelation of how rich life could remain with an incapacitated body when the spirit was unconquered. During the last few days of the patient's life he had a gastro-intestinal disorder, together with difficulty in opening his mouth and in swallowing. He died while he was asleep.

The artificial respiration apparatus has become known as the Bragg-Paul Pulsator, and an electrically worked model has been described by Mr. Paul in the *Proceedings* of the Royal Society of Medicine (1935, xxviii., 436). Its manufacture has been taken up by a firm of safety engineers, Messrs. Siebe, Gorman and Co., of 187, Westminster Bridge-road, London S.W. This firm keeps one instrument which

is available for hire in emergencies. It can be obtained by telephoning Waterloo 6071 by day or night, and arranging for transport. The machine has been used successfully for cases of temporary respiratory paralysis complicating diphtheria, and anterior poliomyelitis. It has been installed in the first-aid room of a large mining concern for cases of gas poisoning. A miniature model is on trial for selected cases of asphyxia neonatorum.

I am, Sir, yours faithfully,

PHYLLIS M. TOOKEY KERRIDGE.

University College, Gower-street, W.C., Feb. 24th.

THE EMBLEY MEMORIAL LECTURE

To the Editor of THE LANCET

SIR,—You were good enough to refer in your issue of Feb. 22nd (p. 438) to the Embley memorial lecture which I delivered in Melbourne in September last, and to note that it has been published in the *Medical Journal of Australia*. I was gratified at the publication of the lecture, but it was accompanied by an editorial expression of opinion against which I have felt it necessary to protest. I would ask if that protest may appear in THE LANCET as it is quite possible that those readers who see the *Medical Journal of Australia* may read the denunciatory leading article there but not the lecture itself. The leading article closes with the following passage:—

"The results of the modern type of cerebral operation speak for themselves. If in the future surgeons are able to evolve newer methods of securing the necessary gentle handling of tissues, a sepsis, hæmostasis, and so forth, together with speed, Dr. Mennell's wish will be gratified. This does not at present seem possible. Dr. Mennell comes from London as an anæsthetist of world-wide reputation. His views on anæsthetics and their administration will be listened to with respect. His utterances on cerebral surgery are to be deplored in a country where neuro-surgeons are trying to bring their art to the high level attained in other parts of the world. It is to be hoped that no serious attention will be paid to them."

In support of this contemptuous view the article says:—

"It can be dogmatically stated that the present so-called slow technique has achieved infinitely better results than were obtained by the older methods. To refuse to follow modern methods with a slavish attention to minute detail is to jeopardise the life of the patient. It has been computed that at present the death-rate for complete removal of cerebral tumours in Australia, even with the use of modern methods, is somewhere in the region of 80 per cent. Cushing has for certain types of tumour brought his mortality down to as low as 7 per cent. What the death-rate with the old rapid methods was may be left to the imagination. . . . When the operation was performed rapidly, it was the exception rather than the rule for the patient to recover."

Since writing the above I have seen the leading article in THE LANCET of Feb. 22nd entitled *The Gentle Surgeon*, and it appears to me apposite to the remarks made in my Embley lecture and for which I am criticised. Nobody can dispute what is said in your leading article about the surgery in the early part of this century, or that the advance in anæsthesia and the better understanding of shock have enabled surgeons to do without the extreme slashing speed formerly necessary. But surely the pendulum has swung too far, more surgeons relying on the better anæsthesia for a too great deliberateness in their methods. Gentleness and care combined with unflurried speed are the essentials of good surgery.

In reply to the *Medical Journal of Australia* I have made the following protest which they will have received by now, and which I shall be much obliged if you will quote.

I am, Sir, yours faithfully,

Harley-street, W., Feb. 21st.

Z. MENNELL.

COPY OF LETTER SENT TO THE EDITOR OF THE
Medical Journal of Australia

Feb. 4th, 1936

SIR,—Holding the views you have so clearly and forcibly expressed in your leader of Dec. 14th, I feel I must first thank you for your courtesy in giving a verbatim report of the Embley lecture I delivered in Melbourne in September, 1935.

The slides, through an error, have been referred to incorrectly, but notwithstanding the well-known difficulty of reproducing coloured slides, they remain clear enough for anyone reading the paper to realise the mistake.

Your leader is another matter; I wrote the lecture with extreme care, and apart from my personal views I am entitled without giving offence to give reasons why a change in anaesthesia has become necessary in certain cases. No one can be more alive than I am to the fact that there are two schools of thought in intracranial surgery, but I am convinced that speed and gentleness are compatible.

You speak first of all of thoracic surgery. Surely it must be admitted that in this work speed is essential whether the operation is done under a local or general anaesthetic. The most recent lobectomy to which I gave an anaesthetic was done in twenty minutes under a very light chloroform anaesthesia, and the excellent result in this and in other cases in which I have been concerned makes me think that in the future the mortality of this very serious procedure may be lowered by a combination of speed and simple anaesthesia.

I can well understand that when you admit an Australian operative mortality of 80 per cent. for the removal of cerebral tumours some change is desirable. Such a mortality is far higher than anything I have met during the thirty-two years I have been giving anaesthetics for such cases. It is because I believe certain neurological surgeons have evolved "the necessary gentle handling of the tissues, aseptis, haemostasis, and so forth together with speed" that "I cannot understand why it is necessary to be so slow" in making a bone flap, &c. Giving anaesthetics to such cases almost daily, and seeing them afterwards, makes it possible to form the opinion which I felt at liberty to express. I do so more readily as I have had the opportunity of seeing cerebral surgery in the new world and on the continent as well as in England. Are Dandy and Adson, whose skill is recognised throughout the world, slow operators? You will naturally reply to this more "vague and general statements." I have figures of course that could be made to prove anything, as they would include many desperate cases and a great variety of tumours.

Here are the figures of four sets of cases.

1. Pituitary tumours operated on by the intracranial route in one year. Twenty-one consecutive cases in 1928 without any untoward symptoms or death. Shortest time forty minutes; longest seventy-five minutes. Neither the late Sir Percy Sargent, who was the surgeon, nor I could claim this a constant figure; but the facts are as stated. Anaesthetic: intratracheal ether with pressure.

2. Gliomata unselected and unclassified. The late Sir Percy Sargent's records, analysed by Mr. Harvey Jackson, who has given me the following data.

Two hundred and sixty successive cerebral gliomata—mortality 12.7 per cent. within forty-eight hours.

This is case mortality and not operative mortality, which would be considerably lower.

3. Hedonal anaesthesia. A hundred and twelve cerebral tumours removed reported in the *Transactions of the Royal Society of Medicine, Section of Anaesthetics, 1922*. No death from anaesthetic within twenty-four hours.

4. To illustrate work with which I am concerned in London (if one may venture to cite English experiences

in Sydney) I quote one of my last cases (surgeon, Mr. Julian Taylor).

H. L. 38. Operation Jan. 31st, 1936, for left parietal endothelioma. Anaesthetic started 11.20 A.M. Large bone flap extending across midline. Tumour, weighing 82 grammes, removed. Part of the bone flap taken out which was invaded by the tumour, and then fixed in position. Wound closed and patient in bed 1 P.M. Condition good. Anaesthetic: Atropine, intratracheal N₂O and O₂, ether.

Feb. 2nd: Patient comfortable. Sitting up in bed eating food.

To-day, Feb. 4th: Pulse 76, temperature 97.6°. Patient sitting up apparently without abnormal symptoms.

The use of local anaesthesia and basal narcotics may be the most usual practice in Australia, it is not here. A small quantity of ether added to continuous stream of gas-and-oxygen is believed to be best after an extensive trial of other methods. I hasten to add pulmonary complications do not occur.

My first impression on reading your leader was surprise, but then it occurred to me how my old friend, Embley, would have risen to the occasion, and I only wish I had his facile pen and power of expression at my command.

I am, Sir, yours faithfully,

Z. MENNELL.

"MORBUS BRITANNICUS"

To the Editor of THE LANCET

SIR,—Dr. Copeland reproaches me with attaching a new label to an old disease. It should be evident from my note that it was not at all my purpose to make new confusing labels to put in text-books, which are most of them surely too big already. I only wanted to call attention to the fact that at the Faroe Islands we observed so many cases of fireman's cramp, among British fishermen only, that we gave the illness a simple geographical name. I emphasised that it is a form of fireman's cramp, and referred to Haldane's researches into miner's cramp, which Macintyre evidently also considers important in the pathogenesis of fireman's cramp. That it is an acute vagotonia I for my part am inclined to doubt, first because similar symptoms are observed in ulcer-stenosis as gastric tetany, secondly because the amount of chlorine in the urine is plainly reduced. Examination of the blood should decide that. The observation that atropine relieves the symptoms in some cases I can confirm, but it does not rule out deficiency of salt or chlorine ions as causing the illness. The fact that a supply of chlorine ions intravenously or rectally can cure the illness at a stroke appears to me much more significant.

I am, Sir, yours faithfully,

Klaksvig, Feroe, Feb. 14th.

SV. E. KOFOED.

DUTIES AND RESPONSIBILITIES OF A SHIP'S SURGEON

To the Editor of THE LANCET

SIR,—After fifteen years ashore in general practice I entered on the duties and great responsibilities of a ship's surgeon on a big liner plying between London and Japan. In common with a large number of my brethren ashore I thought that it would be a light task. I found, of course, that it is a specialised job which needs a considerable time to learn the way of. That by the way. I am hoping that this letter may draw the attention of the profession to those cases which are not suitable to be sent for a "sea voyage." I made the mistakes myself in practice and it is only since I have been at sea that I have realised what gross mistakes they are.

Let me say that the resources of the modern liner are such, nowadays, that almost any treatment can be carried out on board provided that due notice is given of anything special that will be needed. Again,

it is often necessary for a given individual to be conveyed from one place to another irrespective of what he is suffering from. This can be easily arranged, but the surgeon should be notified in good time and certain conditions must be agreed to. It is not with such cases that I am dealing. It is with those patients for whom the doctor in charge prescribes a "sea voyage." I often think that this prescription is sometimes given to get them out of sight and out of mind. The particular types of cases I have in mind are:—

1. *Pulmonary cases with a cough.*—From a physical point of view the rapid changes of temperature on a voyage such as this, together with the extreme humidity experienced after Port Said, are reasons enough to contra-indicate recommending such a case to take a sea trip. But think of the psychological aspect. Everything that happens on board is known all round the ship within a few hours; there are no secrets. What patient can refrain from discussing symptoms, especially a consumptive. The fact becomes known and the patient is ostracised, very kindly, but nevertheless ostracised. I have not dealt with the obvious danger to other passengers in such an enclosed space.

2. *Neurasthenia.*—This is the favourite type to send to sea and the most unsuitable. The phrase includes all types, the most usual of which are (a) melancholic; (b) dipsomaniac; (c) the unstable type.

(a) *Melancholic.*—The opportunities for suicide on board ship must be seen to be believed. There is to start with a long ship's side with sea all around into which the would-be suicide can plunge. He has a cabin to himself in which he can lock himself and do what he pleases. By nature morose he establishes very few contacts with his fellow passengers and goes from bad to worse. The first thing the surgeon hears is that he has gone overboard. Apart from the fact that this costs the company a good deal of money, in stopping the ship and picking him up, it is good marks neither to the doctor who sent him on the voyage for his health nor to the ship's surgeon who knew nothing about him.

(b) *The dipsomaniac.*—This is an obvious case which should not be sent to sea. The opportunities for drinking on board are unlimited. The "chit" system makes it very difficult to check and control the amount of alcohol any given man consumes. And he can always get a drink from a friend.

(c) *The unstable type.*—Until I came to sea I did not know that so many very odd people existed. I have had to deal with borderline cases and oddities of all kinds, and they have all given rise to a great deal of anxiety, chiefly from the danger and opportunity of suicide but also owing to the resentment of other passengers. One lady of uncertain age caused alarm to women passengers by claiming relationship with a different Royal family each day. Another girl was an aggressive nymphomaniac. A man had the habit of wandering around the ship at night waking up complete strangers and demanding all manner of things from cigarettes to typewriters. This last, I found later, a man of good family, had been released from a mental nursing-home two days before the ship sailed and put on board by himself and without notification to anyone.

3. *The venereal case.*—It will hardly be believed that on three occasions I have found, by chance, cases of acute gonorrhœa, travelling in cabins with other passengers, who have been instructed by their doctors to douche themselves in one of the ship's baths. Apart from the danger to his cabin mate,

the fact that the bath will be used by eight or ten other passengers makes such instructions almost criminal.

There are other unsuitable people who are sent to sea for their health, but the above are the most common.

In conclusion let me say that any ship's surgeon, at any rate in the bigger lines, will be always ready to coöperate in any way he can to make the path of a patient easy and as pleasant as possible. If the doctor in charge of the intended passenger will take the surgeon into his confidence, let him have what notes are necessary for the proper understanding of the case and suggestions for the continuance of treatment, much more satisfactory results will ensue.—I am, Sir, yours faithfully,

Feb. 24th.

SHIP'S SURGEON.

A DANGEROUS REMEDY

To the Editor of THE LANCET

SIR,—The *Manchester Guardian* of Feb. 21st reports the case of a 14-year-old boy who was forced by his father to eat a cigarette as a cure for smoking. The father's action appears to have received the approval of the court.

You have previously published notes of certain cases of nicotine poisoning in which patients of mine have been seriously affected by absorption of pure nicotine through the skin. Such experience as I have in this type of poisoning leads me to send you an emphatic protest regarding the treatment of cases of juvenile smoking by the method related above. If this method should be adopted by other parents I think there will undoubtedly be fatalities and it is a pity that approval should have been given to what is obviously a most mistaken course.

When a cigarette is smoked the nicotine is oxidised, but when it is eaten or when a decoction of tobacco is applied to the body there is grave risk of serious poisoning, and I trust that the attention of the authorities may be drawn to what is obviously a little realised but nevertheless serious risk.

I am, Sir, yours faithfully,

Nottingham, Feb. 24th.

L. P. LOCKHART.

THE OXYGEN TENT SERVICE

To the Editor of THE LANCET

SIR,—An oxygen tent of the Guy's Hospital pattern has been sent by the British Red Cross Society to each teaching hospital in London, so that a wide experience of this method of treatment may be gained. In this connexion we have been asked by the society to act as a small medical advisory committee.

We desire to draw the attention of the profession to the facilities afforded by the Oxygen Tent Service, which is at present under our control. For over two years arrangements have been made to send a tent to any part of the country and even abroad at the request of any medical man. A physician, not medically qualified, accompanies the tent. The furthest distance a tent has travelled is to Gibraltar at the request of a well-known physician. Applications should be made to the secretary, Mr. T. W. Adams, A.Inst.P., and the address (for the present) is 25, Upper Wimpole-street, W. 1 (Tel.: Welbeck 1627).

We are, Sir, yours faithfully,

REGINALD HILTON, WILFRED J. PEARSON,
E. P. POULTON.

London, W., Feb. 24th.

WHAT IS SCARLET FEVER FOR THE CLINICIAN?

To the Editor of THE LANCET

SIR,—In the admirable paper on this subject published in your last issue, Dr. F. G. Hobson says much that will be accepted by those who have had experience in throat infections and in scarlet fever—if for a little longer we may be allowed to use that term. It is refreshing to have a challenging article such as this, for the time is certainly ripe to take stock of and to readjust our attitude to streptococcal infection in general. Whether much will be gained by abandoning the term scarlet fever is, however, debatable. Even though it is the name only of a syndrome, and there are, as in all infectious syndromes, borderline and atypical cases, the term is useful. Scarlet fever is a convenient description of a type of streptococcal infection in a non-immune. That the field of streptococcal infection is wider than has been appreciated in the past is no reason why a well-mapped corner of it should lose its notice board.

A fundamental point on which much more evidence is required is the statement that the liability to serious complications appears to be slightly greater in cases without an erythema, or in other words, that erythema is a favourable sign. This surely is exceedingly doubtful. Only an exhaustive clinical study of non-erythematous streptococcal tonsillitis for the periods and under the conditions in which we observe scarlet fever could settle this. After all, the erythema is an indication of non-immunity. It is suggested that a non-immune is better off than a partial immune. If this be so, I do my staff a disservice when I immunise the Dick-positive reactors among them. Given the same streptococcus, is it safer to have scarlet fever than tonsillitis? I doubt it. And if erythema is a favourable sign, why should we give serum, one of the demonstrable effects of which, if given early and intravenously, is to abolish the rash.

If we ask "what is scarlet fever for the clinician" we must also ask "what is streptococcal infection for the bacteriologist." For some little time we have been plating the throat swabs of scarlet fever admissions on blood agar. The cases are typical of the prevailing mild scarlet fever of the district. The striking feature of these plates is the mixed streptococcal infection present. β -haemolytic streptococcal colonies may be scanty, fairly numerous, or numerous, but the other organisms which usually outnumber them are α -haemolytic and non-haemolytic streptococci with a few staphylococci. In one case no β colonies were found, but repeat swabs were not obtained. The picture differs according to the blood plates used, the same swab sown on to (1) horse blood agar, (2) human blood (individual A) agar, and (3) human blood (individual B) agar showed: (1) good growth but no haemolytic streptococcal colonies; (2) good growth with one or two doubtful haemolytic colonies; (3) good growth with numerous typical β -haemolytic colonies. I mention these points to illustrate the complexity of working out throat infections and the need for a standard technique if, as has been suggested, swabs are to be used as a public health measure.

"Scarlet fever" or "streptococcal fever with erythema." Such would appear to be Dr. Hobson's choice. After all a disease is not a thing. There are no infective diseases, there are only organisms infecting hosts and producing no symptoms or varying symptoms. Dr. Hobson may call meningococcal fever a disease, but I might call it a rare complication

following infection of the nasopharynx by the meningococcus. What's in a name? Only a short description of a clinical syndrome and as such it is useful. Scarlet fever is a useful term.

Dr. Hobson's refreshing paper might well have been entitled What can Public Health do for Streptococcal Infection. It is a plea for something more than the abolition of a name. It calls for further study of these infections and a reconsideration of our policy towards them. We want our fever hospitals to do the most needed and most useful work possible and if there are better indications for the admission of streptococcal fever than the presence of a rash, let us use them. But what these indications are and how they can best be applied are wide problems on which much thought will be needed. Should all cases of tonsillitis and other streptococcal infections be notified? I can hear both general practitioners and medical officers of health, with an unusual unanimity, say Heaven forbid. This and many other questions are involved and Dr. Hobson's paper should hasten their consideration.

I am, Sir, yours faithfully,

H. MASON LEETE.

Hull City Hospital, Cottingham, Yorks, Feb. 24th.

To the Editor of THE LANCET

SIR,—The question which forms the title of Dr. Hobson's excellent article is one which has been puzzling many practitioners for a long time. A paper discussing some of the points he raises was contributed by one of us (J. C. S.) to the *Medical Officer* of Jan. 18th last, and a complementary paper by the others (F. E. C. and J. M. W.) is in course of preparation. Meanwhile it may be appropriate to mention one or two of the observations we made during a milk-borne epidemic of scarlet fever, and the steps taken to control it.

In the first place, the tendency of the early cases to show no rash bore out Dr. Hobson's experience. Secondly, he may be interested to know that the Schultz-Charlton reaction, performed as a routine in all cases admitted to the isolation hospital (the majority of which were type 2), gave a positive result regardless of the type to which they belonged; whilst one or two definite type 2 cases gave a definite negative result. Accordingly we regarded the test of no value and discarded it.

In view of the number of cases of streptococcal tonsillitis there had been in the area for some years, and of experience with the epidemic, the following administrative measures were adopted. (1) Notice has been circulated to medical practitioners that the function of the isolation hospital is to deal with all cases which by reason of their infectivity cannot be admitted to a general hospital, but that admission is limited, as far as possible, to patients in the above category who are sufficiently ill to require hospital treatment or are so placed as to be an especial danger to public health. (2) Scarlatinal antitoxin and polyvalent antistreptococcal serum are available free of charge for administration at the patient's own homes by their medical attendant in exactly the same way as diphtheria antitoxin. (3) The question whether a case is notifiable as scarlet fever is for the practitioner to determine; but during the epidemic practitioners were informed that notifications of streptococcal sore-throats, with or without a rash, would be accepted as scarlet fever; and an increasing number of such cases were notified, thereby helping to control the outbreak. (4) The throats of all patients were swabbed on admission to the isolation hospital and also at their own homes by their own

doctors. The swabs were examined for hæmolytic streptococci, and if positive were typed. This was of value in tracing the source of infection and in preventing cross-infection on the isolation hospital.

We note with interest Dr. Hobson's suggestion that the typing of hæmolytic streptococci might be of value clinically. So far as workers have shown up to the present, typing appears to be more applicable to the public health side of medicine—in tracing the source of infection, and in controlling epidemics and preventing cross-infection—than in clinical practice. Gunn, Griffith, and other observers have hitherto failed to trace a definite clinical picture associated with specific types, but it might appear that certain types under certain conditions are more virulent and give rise to more complications, whilst certain others seem to be relatively mild.

We are, Sir, yours faithfully,

J. C. SLEIGH, J. L. MILLER WOOD,
Chelmsford, Feb. 25th. F. E. CAMPS.

TREATMENT OF PSYCHOSES BY PROLONGED NARCOSIS

To the Editor of THE LANCET

SIR,—In his interesting paper in your last issue Dr. D. N. Parfitt records that he used Somnifaine for prolonged narcosis 60 times with 3 fatalities. As this high mortality-rate (5 per cent.) might well dissuade others from carrying out this valuable form of treatment, I should like to point out that it is not in accord with our experience at Cardiff City Mental Hospital, where prolonged narcosis has been carried out in 240 psychotics and neurotics. When somnifaine alone was used we had 2 deaths in 86 treatments (2.3 per cent.); but since glucose and insulin have been used to combat toxic symptoms 154 cases have been treated without a single fatality. A future publication will deal with possible causes of this discrepancy in mortality-rates, and here I will merely state that at Cardiff, with careful nursing in a darkened single room, it is rarely found necessary to give more than 4 c.c.m. of somnifaine in the 24 hours.—I am, Sir, yours faithfully,

P. K. MCCOWAN,
Medical Superintendent, Cardiff City
Mental Hospital.

Feb. 24th.

AN ADDRESS IN HARLEY STREET

To the Editor of THE LANCET

SIR,—A belief common among laymen is that doctors may not advertise; whether the ban is imposed by law or the rules of good form, whether it is *de jure* or *de facto*, does not interest the layman, nor does it matter for the purpose of this letter. The question is: what is "advertising" in the meaning of the ban on professional men? We know that in commercial practice the object of advertising in the broad sense is to draw attention to specific goods; to create the impression in the minds of potential purchasers of the genus of goods that there is none so choice as the species advertised. We know, too, that to all intents and purposes there is no restraint on commercial publicity, and that in this respect trade advertisers enjoy a measure of liberty which is almost immeasurable—such a measure of liberty as is probably without parallel in human things. It may be for good, it may be for bad, but on balance it is probably for good.

Advertising in its popular meaning brings to mind posters on the boardings, pamphlets distributed from house to house, and especially—the best means of all of bringing the commodities of life to the

notice of the public—the newspaper press. All these methods are denied to the professional man, and with the consequence that if he desires to draw attention to himself he must have resort to more subtle means. In the case of the doctor there are in common use the red lamp, the blue lamp, and the brass plate—it may be a personal subtlety to have the plate larger and more brightly polished than his neighbours' plates, and, in some districts, clean curtains point out the doctor's house. The lamps and plate are without reproach in the view of laymen and even commendable since there are times when a doctor is wanted in a hurry.

There is another means of advertising open to the medical man which is not so subtle as he seems to believe; in fact it is becoming so obvious as to be damaging to a section of the profession and I doubt whether it is any longer misleading to the public. I say this as a layman and I may be wrong, but it seems to me, and the opinion is gaining ground, that the fame of "Harley Street"—and by "Harley Street" I mean not merely that thoroughfare but also its environs—is being exploited for advertising purposes. There may be a danger to the profession and to the public in the use of an address merely for advertising purposes. It is even said that not a few charlatans are housed in the district and that the place is as overcrowded—an exaggeration of course—as some of the slums in the East End where several families live in the same room. It ought to be known to the public that "Harley Street" is not a degree but an address.

I am, Sir, yours faithfully,

Whitehall-place, S.W., Feb. 15th. F. C. GOODALL.

THE TREATMENT OF VAGINAL DISCHARGE

To the Editor of THE LANCET

SIR,—The annotation, A Remedy for Vaginal Infections, in your issue of Feb. 15th caused me some astonishment, since it appears to be in the nature of a good advertisement for a proprietary article Devegan. The whole question of vaginal discharge being such a very complicated and difficult one, it seems to me a pity to publish an article of this nature which will make many doctors think that at last a cure for vaginal discharge has been found.

I think you will agree that vaginal discharge is most often due to a chronic endocervicitis, and that this will not be affected by any treatment applied to the vagina. As it is most important to make a complete and thorough gynaecological examination before commencing treatment for vaginal discharge, I feel that it is unwise to recommend a purely vaginal treatment. My own experience of this condition is that a vaginal discharge caused by a localised vaginal infection is very rare; that the presence of the *Trichomonas vaginalis* is very rare; and that, at present, the case for the value of devegan is far from being proved.

I am, Sir, yours faithfully,

Bournemouth, Feb. 19th. S. GORDON LUKER.

. We are glad to have Mr. Luker's views and would welcome other expressions of opinion on the treatment of vaginal discharge. We do not agree with him, however, that it is improper to comment on proprietary preparations of known composition. Many of the most important remedies now in use (from salvarsan and aspirin downwards) were introduced under protected names, and though monopolies are in many ways undesirable they are a recognised condition of modern manufacture, and may be a valuable stimulus to chemotherapeutic research.—ED. L.

RUSSELL'S VIPER VENOM*To the Editor of THE LANCET*

SIR,—Our attention has been drawn to a disturbing statement, reported in the daily press, and attributed to Dr. Peck, of New York, to the effect that the use of snake venom as a hæmostatic has been practically abandoned in the United States on account of the severe reactions produced. Since Dr. Peck is well known for his treatment of hæmorrhagic states by the injection of moccasin venom, which frequently produces local reactions (*THE LANCET*, 1935, i., 997), we believe that the statement refers to this procedure. Moreover, we are not aware that Russell's viper venom has received a trial in America. In the many cases of hæmorrhage treated at St. Bartholomew's Hospital and elsewhere, by the local application of Russell's viper venom, we have not observed any

reaction or local effect other than coagulation of the issuing blood.

In view of the apparent confusion, it may be useful to summarise the venoms that have been employed therapeutically. Cobra venom has been used as an analgesic, particularly in cancer; this and puff adder venom in the treatment of epilepsy; moccasin venom has found an application in certain hæmorrhagic conditions and skin diseases. All these are given by injection. Dilute solutions of Russell's viper venom are only employed as hæmostatic applications direct to bleeding surfaces. This venom is, in our opinion, the most effective local hæmostatic available.—We are, Sir, yours faithfully,

R. G. MACFARLANE,
BURGESS BARNETT.

Pathological Department, St. Bartholomew's
Hospital, E.C., Feb. 25th.

OBITUARY**PRIESTLEY LEECH, M.D. Lond., F.R.C.S. Eng.**

CONSULTING SURGEON, ROYAL HALIFAX INFIRMARY

Dr. Priestley Leech, who died on Feb. 7th, had been in indifferent health for some months but had continued in harness until a few weeks before his death. A native of Halifax he was educated at Owens College, Manchester, where he took honours in several scientific subjects. He qualified as M.R.C.S. Eng. in 1885 and graduated M.B., B.S. Lond. in 1888, obtaining the F.R.C.S. Eng. in the following year. He was for a time house surgeon at the Warrington Infirmary but returned to commence general practice in Halifax, and in 1890 was appointed honorary medical officer to the Royal Halifax Infirmary, an institution which he served until resignation in 1919 when he was made honorary consulting medical officer. He was also the medical officer in charge of the venereal diseases clinic at the Infirmary.

A colleague "J. F. H.," writes: "Dr. Priestley Leech carried on a large general as well as a surgical practice, and for a long period he was the best known consultant over a wide area outside his own town. A voracious reader and a keen observer, he acquired a large practical experience so that his judgment was always sound and valued by his colleagues, and his patients had every reason to be grateful for his skilful and capable surgery. His reputation was more than local. For many years he contributed the article on General Surgery in the *Medical Annual*. He was an expert linguist and abstracted the items from the original. In spite of his very busy life he found time to undertake much work for the profession. He had been chairman of the local medical society, the Halifax division of the B.M.A., and of the Leeds and West Riding Medico-Chirurgical Society. During the war he did much valuable surgical work amongst the soldiers in his own hospital and at St. Luke's hospital, Halifax. When his work would allow him a few hours of relaxation he indulged in his favourite sport of fishing, of which he was an enthusiast. His reminiscences of fishing men and fishing dinners were always entertaining."

Dr. Leech was in his 74th year when he died, and leaves a widow and one son. He celebrated his golden wedding last year.

ARTHUR JAMES ARCH, M.R.C.S. Eng.

Dr. A. J. Arch, who died on Feb. 14th aged 58, was a well-known Coventry practitioner, holding a

large number of public appointments. He was born in Coventry, the son of Mr. James Arch, who was for a long period clerk to the Coventry Board of Guardians, and received his medical education at Birmingham, qualifying as L.R.C.P. Lond., M.R.C.S. Eng. in 1904. He was one of the best known general practitioners in Birmingham, having an extensive general circle of patients, while he was closely identified with National Health Insurance administration, being a member of the Coventry Insurance Committee for 14 years and for a considerable period vice-chairman of the Coventry Panel and Local Medical Committee. Dr. Arch was also public vaccinator when the duties of the Poor Law Guardians were taken over by the municipality, and until the time of his death was public vaccinator under the new authorities. He had been a considerable athlete in his younger days.

ALEXANDER WAUGH, M.B. Glasg.

The recent death at Prenton, Birkenhead, of Dr. Alexander Waugh, has removed a practitioner who for a considerable period occupied a prominent position in Skipton. He received his medical training in Edinburgh and Glasgow and graduated in medicine at the University of Glasgow in 1899. He now practised at Skipton where he had a large practice, being also medical officer to the infectious diseases hospital and poor-law officer to the Skipton sub-district. While at Skipton a serious small-pox epidemic occurred, and Waugh, who had already shown keenness in regard to prevention and suppression of infectious diseases, was so successful in the measures which he took that he was thanked by the urban council for his labours. He left Skipton in 1909, his residence there being terminated by a breakdown in health leading to a sea-voyage. On his return he entered practice in Birkenhead. He did much good work at home during the war, and on the cessation of hostilities held for a period a position under the Ministry of Pensions. He was also medical examiner to many insurance companies and gave medical advice to various shipping companies. Dr. Waugh had been in bad health for the last ten years and was 72 years of age at the time of his death.

ST. GEORGE'S-IN-THE-EAST HOSPITAL.—A new out-patient department at this hospital has been planned by the London County Council at a cost of £20,000. It will include two new receiving wards and an antenatal unit.

ENDEMIC YELLOW FEVER IN TOWN, VILLAGE, AND JUNGLE

THERE has been a revolution in the last decade in ideas of the prevalence and origin of yellow fever, especially in South America. In 1926 the disease was thought to be confined to the north-east corner of Brazil, and it was believed that with anti-mosquito measures it was rapidly disappearing and could soon be eliminated. It was considered a disease limited to the cities and maritime parts of the east coast and to some extent to the shores of the Amazon. The only infecting agent of importance was then thought to be the *Aedes (Stegomyia) aegypti* mosquito which was found only in the houses of an urban population. To-day, however, it is known that yellow fever is widespread throughout the two-thirds of the continent north of Paraguay and east of the Andes. The more intensive the investigations, the more cases are discovered in places remote from cities and maritime transport, in the jungles and plains of the interior, with sporadic outbreaks in isolated settlements where no means of contact can be found. It is now known that the disease can be transmitted by a large variety of mosquitoes and in the complete absence of the stegomyia. Hope of controlling the disease solely by anti-mosquito measures has been abandoned and a new means of prevention has had to be devised.

THE CAMPAIGN AGAINST THE DISEASE

Dr. F. L. SOPER, of the International Health Division of the Rockefeller Foundation, outlined this revolution in the history of yellow fever in an address given at the London School of Hygiene and Tropical Medicine on Feb. 24th. Warfare against the disease had, he said, been successfully waged in South America since 1914, and from 1920 to 1924 it had disappeared from the equatorial zone. In 1927 there was a period of 11 months without a single notified case in the continent. The next year, however, it reappeared in Rio de Janeiro after an absence of 20 years and again in north-east Brazil. In 1929 it had once more spread along the coast and up the Amazon valley. There were isolated outbreaks in Colombia and Venezuela with no known focus of infection or possible contact with other infected places. The year 1930 saw a campaign of intensive anti-mosquito measures throughout the country, not only in the cities but in small towns and villages. These methods were still inadequate and it was decided to hunt for the mosquito in unsuspected places and for the disease in unsuspected persons. The very valuable "viscerotomy service" was organised. Liver tissue, removed post mortem with the viscerotome from every person dying within ten days of the onset of any disease, was sent to the laboratory; it was found that a proportion of the specimens had the lesions of yellow fever. The mouse-protection test¹ was first used on a large scale in 1931, and it was then discovered that over an area of two-thirds of the whole continent every community had a varying proportion of acquired immunity, showing that no part of that area was free from the disease, in spite of the absence of *A. aegypti*. Even young children had this immunity and it was most evident in Indians remote from any

possible known source of infection. This discovery made some investigators sceptical of the value of the test.

During the next three years there were several isolated outbreaks, one among troops in Bolivia that were being acclimatised in preparation for the Chaco war, but their significance was not remarked, though they had taken all by surprise. In 1935 the investigators were startled by a large outbreak far beyond their expectations in an area hundreds of miles from any contagious focus, believed to be free from yellow fever and investigated only to complete the survey. The mouse-protection tests had given a proportion of positives of only 1.6 per cent., and yet, soon afterwards, evidence was found that there must have been thousands of cases of the disease spread over an area of more than 100,000 square miles. The disease did not come into the cities, of which there were several of a population of 30,000-40,000, but the outbreak still continues.

JUNGLE YELLOW FEVER

These events led to the discovery of a second type of the disease known as jungle yellow fever, to distinguish it from that due to the stegomyia. This was prevalent in the remote districts and was believed to be traceable to infected wild monkeys, though there were no *A. aegypti* for hundreds of miles. The diseases were, however, identical in all other respects, not only clinically but also in their response to cross-immunity and monkey transmission tests and in the pathological lesions produced. The disease, it was true, was at present sporadic but there was no reason why the cities might not become heavily infected from immigrants. The stegomyia type was confined to the houses, whereas the jungle fever was found only in those who lived in close proximity to uncut forest. In fact, in many parts it was known to the people as "fiancé's fever" for it infected young men who had left the community to prepare a home further afield. Graphs of the age-incidence were very illuminating in contrasting the two types of the disease. The stegomyial yellow fever in rural districts had its greatest incidence in the early years of life, whereas the jungle type occurred in the young adults group, that is to say, in those that worked in the field and away from their homes. In towns, stegomyial fever showed the early peak found in the rural districts, but also a second peak in early adults, similar to that of the jungle disease. This second curve was due to immigration from the country of non-immune people who quickly fell a prey to the *A. aegypti*. It was also notable that the disease was one that proved fatal to children, the greatest incidence being under 5 years and the next greatest between 5 and 9 years.

Dr. Soper showed a number of photographs of the type of settlement in which a large proportion or all of the people had an acquired immunity. The disease was never present where there was no adjacent uncut jungle, but even small areas of forest in open prairie country were virulent sources of infection. That the wild monkeys were responsible had been proved, for in some investigations 20 per cent. of the monkeys killed in the jungle were found to be infected with yellow fever. This source of infection would never be eradicated but he believed that the new preventive measures against the stegomyia mosquito in the towns would prevent epidemics. It had been discovered that if the breeding-index—i.e., the proportion of houses in the town harbouring the mosquito—was reduced to

¹ Yellow fever virus, fixed for mice, is inoculated intraperitoneally into a mouse, together with the serum to be tested. A simultaneous injection of starch solution into the brain localises the virus and if the serum lacks protective power (a negative result) the animal dies of yellow fever encephalitis.

below 2 to 3 per cent. and maintained there, the probability of infection was remote. Every town had now a periodic examination at least every quarter. If *A. ægypti* was discovered, every house was searched for possible breeding-places, adult mosquitoes were captured, and exposed water was covered with petroleum. In this way even the large cities were able entirely to eliminate the mosquito for several weeks, before one was found, introduced from another place. The viscerotomy service was still continued in every district, and it was the duty of a responsible layman if necessary to provide the specimens. There was also a close coöperation between the health services of the different sea-ports, and information was exchanged which was of even greater importance than the incidence of the mosquito or disease in each individual city.

THE PROBLEM IN AFRICA

In the discussion that followed the address, reference was made to the spread of yellow fever in Africa. Dr. Soper did not believe that because certain areas such as the Sudan were at present free from infection there would be no epidemic in the future; on the contrary, the experience of South America had shown that after apparently

absolute freedom there might be widespread outbreaks. He felt sure that there was jungle yellow fever throughout a large area as far east as the Great Rift Valley; in fact in a recent journey there he himself had found cases of this type in Uganda. Kenya was free because of the nature of the country and its vegetation, but as far as he knew there was no eastern limit to possible infection in the Sudan. The spread of motor traffic would bring civilisation; that brings clothing, and clothing implies washing, and washing, water; but in a dry country all the water was domestic and therefore measures against the *A. ægypti* were essential and it would not be difficult to eradicate the species even in the land that gave it its name. The breeding-index should be lowered to the safe limit in every town in and near the endemic regions; these measures were assisted by the fact that dengue fever was also transmitted by *A. ægypti* and that it had been successfully treated. Dr. Soper thought that even the most stringent precautions in air transport would not of themselves guarantee immunity; the other preventive measures were essential. The whole question of the prevalence in Africa of the jungle type of yellow fever had not yet become clear and more research was necessary.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Juvenile Training in Schools

In the House of Commons on Feb. 19th Mr. C. S. TAYLOR moved:

That this House is of opinion that a greater degree of technical and physical training should be given to juveniles before leaving school, so that they may be better fitted for the changing conditions of industrial and economic progress.

He said that to work well one must be fit. He felt the necessity for developing in the schools a system of physical training. A standard syllabus approved by the Ministry of Health or Board of Education and administered by qualified instructors would help to produce the bodily fitness which was so desirable. Unqualified instructors might do an immense amount of damage; unsuitable exercises might have a very detrimental effect on the health of the children. It was up to the Government now to press upon the local education authorities the need for expanding physical training. It was time for the Government to make a further appeal to local authorities to provide holiday and school camps for the youth of the country. These camps would supplement the physical efficiency which they all desired. He also asked, must the State rely on public charity for the provision of school playing fields? Building was going on to such an extent that all the available open spaces round our great cities would be occupied unless the Government took steps to remedy this great defect.

Mr. CRAVEN-ELLIS seconded the motion.

Mr. MORGAN said he was not too easy about the glib talk about the Army of physical organisers. He would impress upon the Board of Education this point: physical education was something much more than "physical jerks." To put it in a nutshell, physical training without medical supervision and advice might be very harmful. Mr. Malcolm Stewart, Commissioner for the Special Areas, in his report, referred to children suffering from malnutrition and children with a tendency to tuberculosis. In such cases a set form of physical exercises would be the worst possible thing for the child. With the demand for greater opportunities for physical training

he was in the greatest sympathy, but he did not think they should go mad about it. Do not let it be said that they were training a nation of mechanical robots finely developed from the neck downwards. School existed for something higher and better than that.

Mr. MARKLEW said that the first essential of physical fitness was proper nourishment of the body and a sufficiency of the right kind of food. Let hon. Members turn their attention to measures whereby parents might provide their children with such food. If the elementary needs which were indispensable for physical health were satisfied young children would show how to keep themselves fit by indulgence in that healthy play in which children did not need a great deal of instruction.

Viscountess ASTOR said that the most important of all the subjects before the country to-day was the number of children in the elementary schools who were physically unfit because they were under-nourished or mal-nourished. She was all for fitness, and did not even mind the children being drilled. There were 95,000 children in the elementary schools who were unfit, but they had found a way out. She hoped that they were soon going to see a tremendous development in open-air nursery schools. That was the real proper way to deal with this question.

Mr. OLIVER STANLEY, President of the Board of Education, replying to the debate, said that one of the most important requests which his department made to local authorities in the circular on physical training was the importance of organisation. They did not rely on charity for playgrounds and playing fields for their schools. For a long time local authorities and the State had spent large sums on their provision. Nor was it fair to overlook the amount of actual physical instruction which was given in schools or the amount of time devoted to games out of school hours at the expense of the teachers' time and trouble. He hoped that the circular which the Board of Education had issued would have the effect of stimulating what was already a largely growing interest in physical education, not only games, but training as well. He was sure that the fact that the House would unanimously assent to the motion would be helpful in the campaign in which all of them were interested.

After further debate the motion was agreed to.

The Milk Bill

On Feb. 20th, in the House of Commons, Mr. ELLIOT, Minister of Agriculture, moved the second reading of the Milk (Extension of Temporary Provisions) Bill. He said that the debate on the financial resolution had dealt with the question of nutrition. He fully sympathised with that, but the really important fact was that the industry must be kept going. The milk must exist before it could be distributed. They must also remember that the dairy industry did not consist merely of milk production, but also that of butter and cheese—which were, after all, nutritious, valuable and protective foodstuffs, full of vitamins. If, as had been suggested, the £2,500,000 subsidy given to butter and cheese manufacture were used for subsidising the liquid milk market, that would not solve their problems, it would allow of a reduction of only one quarter of one farthing per cent. in the price of liquid milk; and who would say that such a reduction would lead to an enormous expansion in consumption? It had also been stated that one of the reasons for the lack of success of the milk scheme was that milk for schools was taken into account in computing unemployment allowances, and that consequently parents preferred to maintain their allowances and not to have the free or cheap milk in the schools. He was informed that that was not so. In calculating unemployment allowances the Unemployment Assistance Board ignored entirely the provision of free milk for school-children, and also the provision of milk at a reduced price. The poor-law division of the Ministry of Health stated that it was practically certain that the public assistance committees did not take cheap milk into account in assessing poor relief. Allowing for the fact that the milk-in-schools scheme was operating in the great majority of the large urban schools it was probable that about 92 per cent. of the children attending public elementary schools were in schools where the scheme was in operation. The fact that less than half the children were taking milk was not primarily due to the absence of facilities but to other factors. This emphasised the desirability of having a further period for test and experience, so that they might find out what all the factors were, and thereby be in a better position to deal with them when the Government brought forward their long-term legislation.

Provision of milk for children during week-ends and holidays was already made in the milk-in-schools scheme. The Board of Education proposed in the next half-yearly returns from the schools to ask whether such arrangements were actually made. As to the improvement in the cleanliness of the milk supplied, the right hon. gentleman said that in December last over 25 per cent. of the milk had been brought up to the standard of Grade A or Accredited Milk. In the week ending Feb. 11th there were over 15,000 accredited producers in England and Wales, and they were producing one-third of all the milk sold under wholesale contract for liquid consumption.

The motion which Mr. Alexander was going to move on behalf of the Labour Opposition referred to the desirability of making milk products available at a price within the compass of the lowest income. The policy of the Government had not only been directed towards that end but had secured that end. Without Government assistance there would have been a widespread crash in the dairy and liquid milk industry. During the two years since the House voted this subsidy over 1,000,000 tons of butter and nearly 500,000 tons of cheese had been consumed in this country. If we had bought the butter eaten in the last two years at 1929 prices it would have cost £100,000,000 more. How small in comparison was the rebate which has been given to the producers in this country. At 1925 prices it would have cost £116,000,000 more. Since 1925, and even since 1929, great strides had been made towards the provision of ample supplies within the reach of all.

These calculations were unfamiliar and no doubt would attract attention. They were fundamentally the justification for bringing forward this Bill. As regards malnutrition, he thought that there was a widespread evil of that sort, but he did not think that any dietetic authority would challenge the proposition that a greater proportion of this nation than of almost any other nation in the world was adequately nourished, that that proportion had risen in recent years, and that the nourishment of this country had improved and was improving more rapidly in recent years than it had done in the long periods before. Every speech made by Ministers on the 1934 Act had stressed the importance, from the point of view not only of agriculture but of national health, of the increased consumption of liquid milk, and the milk-in-schools scheme has been a substantial contribution to that end. They all wanted to see the public drinking more milk. That was the main object of this Bill. The problem could not be insoluble and must not be insoluble.

Mr. ALEXANDER moved the following amendment:

That, in the opinion of this House, it is necessary for the improvement of the national physique and for dealing with the widespread evil of malnutrition that the consumption of liquid milk should be increased and encouraged by the provision of ample supplies at a price within the compass of the lowest incomes, and this House therefore declines to assent to the Second Reading of a Bill which merely continues a State subsidy without making provision for the effective reorganisation of milk production or for the establishment of an efficient system of distribution, whereby the public need, and particularly the need of children, expectant mothers, the sick and infirm, may be adequately met.

To anyone concerned with social improvement, he said, it seemed a great anomaly that there should be hundreds and even thousands of families who were unable to get anything approaching an adequate supply of liquid milk, while at the same time milk was being sold at a loss for manufacture at a price so low as 3½d. per gallon. If the Minister admitted the need for a subsidy there was surely a case for widening the extent of the subsidy. They were now supplying milk to schools at ½d. per third-of-a-pint bottle, instead of 1d. as formerly, and yet on the Minister's figures nearly half the school-children were still without milk. He (Mr. Alexander) did not believe that any of the reasons given were as important as that of poverty. He hoped that the Minister would not take the propaganda of the Milk Board on the improvement in the cleanliness of the milk supply as being the whole of the truth. He thought that it was beginning to regularise what had already been introduced for a long time by the important retail and pasteurising organisations in the country. As to the cleaning-up of herds, he believed that a much bigger and a more intensive and scientific scheme was required if they were to get rid of a state of affairs in which 40 per cent. of the herds were reacting to the tuberculin test. There was no doubt that the present price level was too high. The producer needed to be gingered up into more efficient production and a more efficient method of distribution was also necessary. If they were to have a really efficient distribution of clean, healthy bottled milk to all the population, and not merely to sections of it, they must have a real national basis of organised distribution.

After further debate, the amendment was negatived by 201 votes to 121 and the Bill was then read a second time.

In the House of Lords on Feb. 20th the National Pension Fund for Nurses Bill was read a second time.

On Tuesday, Feb. 25th, in the House of Commons the Milk (Extension of Temporary Provisions) Bill passed through Committee.

HOUSE OF COMMONS

WEDNESDAY, FEB. 19TH

Lymph Supplies for Public Vaccination in Scotland

Mr. GROVES asked the Secretary of State for Scotland the name of the firm of lymph manufacturers from whom his department obtained supplies of lymph for vaccination purposes; whether the firm in question held a licence to manufacture lymph under the Therapeutic Substances Act, 1925; and whether he would consider the desirability of obtaining lymph in future from the English Government lymph establishment instead of from private manufacturers.—Sir GODFREY COLLINS replied: The Department of Health obtain their lymph from the Jenner Institute for Calf Lymph, Limited. This firm holds both an importing and a manufacturing licence, under the Therapeutic Substances Act, 1925. The department have found that the keeping qualities of the lymph made by the firm mentioned are peculiarly suited to Scottish needs, and I see no reason therefore to make any change.

Malaria Epidemic in Ceylon

Lieut.-Commander FLETCHER asked the Secretary of State for the Colonies the total number of deaths in Ceylon from malaria between November, 1934, and April, 1935; if he was satisfied that adequate supplies of quinine were available during the whole of this period; and if the report of Colonel Gill on the subject of the malaria epidemic in Ceylon would be published.—Mr. THOMAS replied: During the epidemic it was not possible to secure accurate statistics as to the causes of all the deaths that occurred. Malaria was probably a contributory cause in the case of many deaths attributed to other diseases. I am afraid that I cannot give a more accurate figure than that contained in my reply on Feb. 12th, which indicated the excess of deaths over the normal figure during the epidemic period. Colonel Gill reported that there was never any shortage of quinine. His report has been published as a sessional paper in Ceylon, and I shall be glad to place a copy in the library of the House.

Small-pox and Vaccination of Children

Mr. BROAD asked the Minister of Health how many deaths of children under five years had been registered from small-pox; and how many had been registered as being caused by, or associated with, vaccination since Jan. 1st, 1908, when the present conscience clause came into force.—Sir KINGSLEY WOOD replied: The total numbers for the period from Jan. 1st, 1908, to Dec. 31st, 1935, are 96 and 216 respectively.

Municipal Maternity Homes in Lancashire

Mr. GORDON MACDONALD asked the Minister of Health the number of municipal maternity homes in the administrative county of Lancashire, including the boroughs, in each of the last five years for which figures were available.—Sir KINGSLEY WOOD replied: According to returns furnished to my department by the local authorities, the number of municipal maternity homes in the administrative county of Lancashire, including the non-county boroughs, was 5 in each of the years 1930 to 1934.

Midwives in Lancashire

Mr. GORDON MACDONALD asked the Minister of Health the number of practising midwives in the administrative county of Lancashire, including the boroughs, in each of the last five years for which figures were available.—Sir KINGSLEY WOOD replied: According to returns furnished to my department by the local authorities, the numbers of practising midwives in the administrative county of Lancashire, including the non-county boroughs, have been as follow:—

Year.	Midwives.	Year.	Midwives.
1930	603	1933	625
1931	601	1934	656
1932	610		

Births in Lancashire Municipal Maternity Homes

Mr. GORDON MACDONALD asked the Minister of Health the number of births in the municipal maternity homes in the administrative county of Lancashire, including

the boroughs, during each of the last five years for which figures were available.—Sir KINGSLEY WOOD replied: According to returns furnished to my department by the local authorities, the numbers of births in the municipal maternity homes in the administrative county of Lancashire, including non-county boroughs, were as follow:

Year.	Births.	Year.	Births.
1930	816	1933	922
1931	778	1934	975
1932	865		

Anæsthetics Used in Surgical Operations

Mr. GROVES asked the Home Secretary what anæsthetic was used by Dr. Adli Samaan at University College, London, in the case the report on which was published in the *Journal of Physiology*, August 22nd, 1935, under the title *The Effect of Pituitary, Posterior Lobe*.—Mr. GEOFFREY LLOYD, Under Secretary, Home Office, replied: I am informed that the operations described in the paper to which the hon. Member refers were, as stated in the footnote on page 37, performed by Dr. G. W. Theobald, and that they were performed under full anæsthesia after a preliminary injection of morphine, the anæsthetics being chloroform and ether.

THURSDAY, FEB. 20TH

Colliery Employee and Pneumoconiosis

Mr. HOPKIN asked the Home Secretary if he was aware that Sidney Norton, recently employed at the Great Mountain Colliery, Tumble, had been certified as suffering from pneumoconiosis in the third stage; that Norton had worked for the last 14 years on the screens but did not come under the Silicosis Order and would therefore not receive compensation; and would he consider amending the above order to include men who worked in or about the mine.—Sir JOHN SIMON replied: This case has not, I understand, been before the Medical Board, and I have no information in regard to it. The Home Office is not in possession of any evidence that work on the coal screens gives rise to silicosis, but if the hon. Member will send me particulars of the case, including the medical certificate, I will consider them and, if necessary, inquire further into the matter.

Mr. E. J. WILLIAMS: Will the Home Secretary give attention to the whole question, as there is great dissatisfaction in all areas that these respiratory diseases are leading to this particular form of disability?

Sir J. SIMON: As a matter of fact I have had the matter very much under my attention in connexion with various cases, but I was only aware of this particular matter when I saw the question.

Mr. WILLIAMS: Is the right hon. gentleman aware of the case recently decided in the High Court, and if so will he further consider revising the Order?

Sir J. SIMON: It was to the Court of Appeal that the decision was referred.

Mr. WILLIAMS: To the House of Lords.

Sir J. SIMON: No, not the House of Lords. The matter has recently been before the Home Office and gone into very fully with the representatives of the men.

Publication of Offensive Evidence in the Courts

Mr. DAY asked the Home Secretary whether he would consider introducing legislation to amend the present procedure in the courts so as to provide that all evidence of a shocking or offensive character in cases of alleged murder or other serious felonies should be taken in camera.—Sir JOHN SIMON replied: No, Sir. I do not consider that it would be in the public interest to amend the law in the sense suggested. If the hon. Member has in mind the control of newspaper reports, I doubt if legislative restrictions could properly go beyond the provisions on the subject in the Judicial Proceedings (Regulation of Reports) Act, 1926.

Mr. DAY: Does not the right hon. gentleman consider that the publication of some of the details in these cases has a bad influence upon younger minds?

Sir J. SIMON: I think that the hon. gentleman had better look at the section in the Judicial Proceedings Act, 1926, which will cover a great deal he has in mind.

Expressions of Opinions by Coroners and Juries

Sir JOHN HASLAM asked the Home Secretary whether, in view of the recent case when a coroner and the coroner's jury inquiring into the death of a footballer censured the conduct of a football referee, and in view of other such cases, he would introduce legislation to prevent coroners or their juries expressing any such opinions or taking any action other than to ascertain the cause of death of the deceased.—Sir JOHN SIMON replied: The recent report of the Departmental Committee on Coroners contains recommendations on the subject matter of my hon. friend's question, and this report is at present under consideration.

Sir J. HASLAM: May I ask whether from his unrivalled experience as a lawyer and in his present office the right hon. gentleman does not think it is desirable that something should be done so that people are not condemned by a coroner in public in their absence, and also that a coroner's jury should not be allowed to express an opinion when the accused has never been invited to attend the inquiry?

Sir J. SIMON: The report of the Committee on Coroners discusses this matter, and these considerations are fully set out.

Mr. RITSON: Is the right hon. gentleman aware that a jury was only stopped from giving their verdict by a very clever handling on the part of the police; that some of us were there on that occasion, and before he condemns the coroner will he ask for further evidence?

No further answer was given.

Maternal Mortality

Mr. GEORGE GRIFFITHS asked the Minister of Health the number of deaths from and arising out of childbirth for the years ended Dec. 31st, 1932, 1933, 1934, and 1935.—Sir KINGSLEY WOOD replied: The following are the number of deaths registered in England and Wales. A.—Classified to pregnancy and childbearing. B.—Not so classified but returned as associated with those conditions.

	A.	B.
1932	2587	713
1933	2618	828
1934	2748	747
1935	Not yet available.	

Hospitals and Ambulance Services

Sir PERCY HARRIS asked the Minister of Health whether his attention had been called to the recent case that came before the Stepney coroner of a woman having to wheel the dead body of her child through the streets to the London Hospital for a post-mortem examination because the hospital was not able to provide an ambulance; and whether he would endeavour to see that there was closer coöperation between the private hospitals and the municipal ambulance to prevent incidents of this character.—Sir KINGSLEY WOOD replied: I have seen a newspaper report of this case and am making inquiries. I will communicate with the hon. Member when I am more fully informed of the circumstances.

Insanitary Slum Dwellings in Bethnal Green

Sir PERCY HARRIS asked the Minister of Health whether his attention had been called to a lot of bad slum courts in Bethnal Green which had been the subject of a survey by the Bethnal Green Housing Association, especially to Busby-square, where the total population appeared to be 53 persons in 1 three-room and 10 two-room houses, the area of the site being 2686 square feet, including the yard, &c.—i.e., one-sixteenth of an acre; whether he was aware that the lavatory arrangements were in a most unsatisfactory condition; whether he could find out if anything could be done to provide alternative accommodation for the people living under these conditions; and whether, when that was available, the court could be cleared.—Sir KINGSLEY WOOD replied: My attention has been called to this matter. The London County Council and the Bethnal Green borough council are engaged in dealing in close coöperation with slum areas in the borough. I understand that the area referred to will be dealt with as soon as practicable.

Sir P. HARRIS: Does not the right hon. gentleman realise that this is a very special cases and that it should have priority over other case that are not so urgent, because of the appalling conditions prevailing?

Sir K. WOOD: I have no doubt that the London County Council and the Bethnal Green borough council have this matter in hand.

Milk Designation Order

Mr. THOMAS WILLIAMS asked the Minister of Health whether his attention had been called to the recent criticisms of the new Milk Designation Order; and would he undertake to re-examine the question, with a view to helping the campaign for pure milk instead of deteriorating the standard already attained.—Sir KINGSLEY WOOD replied: Various representations have been made to me on the draft Milk (Special Designations) Order, and they will have my fullest consideration before the Order is finally settled.

Voluntary Hospitals and General Nursing Council Rules

Mr. BOULTON asked the Minister of Health if he was able to give an undertaking that the boards of management of the principal voluntary hospitals of the country should be consulted before any action was taken to amend Rule No. 4 (1) of the Nurses Registration Act, 1919, or before it became law.—Sir KINGSLEY WOOD replied: I do not think it necessary to adopt the course suggested by my hon. friend. The proposed new Rule 4 (1) (a) of the General Nursing Council, to which I presume he is referring, has been published in the press, and it is open to any interested party who objects to the rule to make representations to me before I approve it under the Act. I may add that the voluntary hospitals are represented on the General Nursing Council.

Prevention of Silicosis

Mr. HOPKIN asked the Secretary for Mines if he was aware that a number of men from 25 to 35 years of age were being certified as suffering from silicosis in the anthracite district of South Wales; and what practical steps were being taken to deal with the prevention of this disease.—Captain CROOKSHANK replied: The answer to the first part of the question is Yes. As regards the second part, I would refer the hon. Member to my reply to his question of Feb. 13th.

Diabetic Patients and Motor-car Driving

Mr. GROVES asked the Minister of Transport, in view of the fact that from time to time drivers of motor-cars were prosecuted on the ground of being in charge of a motor-car while under the influence of drink, and in defence it was stated that their condition was due to the effect of insulin dosage, whether he would make it a condition for granting a licence to a diabetic under insulin treatment that he should state this in the declaration as to physical fitness required when applying for a driving licence.—Mr. HORR-BELISHA replied: On the facts placed before me, I do not think that I should have sufficient ground for taking the course recommended by the hon. gentleman.

MONDAY, FEB. 24TH

Protective Measures against Air Attack

Captain MACNAMARA asked the Home Secretary, in view of the fact that the Army, the Royal Air Force, the police, ambulance and hospital services, decontamination squads, &c., were administered by the War Office, Air Ministry, Home Office, and Ministry of Health, often working through local authorities, had any arrangements been made by districts for all such services to be under the actual command of one officer in the event of an air attack on this country; if so, was such an officer given facilities for the coördinated training of these services in peace time; and who was the official responsible at present in any district for ordering a black-out in the event of a sudden air attack.—Mr. G. LLOYD, Under-Secretary, Home Office, replied: Subject to general guidance from the Air Raids Precautions Department of the Home Office, the responsibility for working out and

coördinating necessary measures of precaution against the emergency of air attack rests with the various local authorities. The question of the form of executive organisation to be adopted in the event of war is under consideration. With regard to the last part of the question, it would fall to the Secretary of State for the Home Department in time of war to issue any general orders that might be necessary for the regulation and restriction of lighting. It would be the duty of the chief officer of police in each district to make the necessary arrangements for giving effect to any such orders.

TUESDAY, FEB. 25TH

Free Meals for School-children in Greenock

Mr. DAVIDSON asked the Secretary of State for Scotland the total number of school-children in Greenock receiving free meals as necessitous cases.—Colonel COLVILLE, Under-Secretary of State for Scotland, replied: The number of children receiving free meals on the 20th of this month was 163. In addition, about 4000 receive free milk under a scheme approved under the provisions of the Milk Act, 1934.

MEDICAL NEWS**University of Cambridge**

On Feb. 22nd the following degrees were conferred:—

M.D.—W. S. C. Copeman, G. D. Kersley, Frank Goldby, and E. S. Stern.

M.B., B.Chir.—E. J. Currant, B. H. Page, and J. B. C. Murdoch.

M.B.—W. I. Bain, J. H. Walters, and G. O. Brooks.

B.Chir.—A. F. Bryson and P. G. Scott.

University of London

The university chair of dietetics tenable at St. Thomas's Hospital medical school is to be transferred to University College Hospital medical school for five years.

Mr. H. L. Eason has been reappointed representative of the University on the General Medical Council.

On March 2nd, at 5 p.m., at University College, Gower-street, W.C., Dr. Charles Reid will give the first of four Monday lectures on the endocrine organs in relation to metabolism.

Society of Apothecaries of London

At recent examinations the following candidates were successful:—

Surgery.—H. Bentovim and H. Burrows, Univ. of Manch.; and O. A. L. Goode, Univ. of Leeds.

Medicine.—H. A. Koretz, Univ. of Manch.

Forensic Medicine.—H. A. Koretz, Univ. of Manch.

Midwifery.—H. A. Bhattacharji, Univ. Coll. Hosp.; J. A. G. Gulliford, Welsh National School of Medicine; and J. F. O'Malley, Guy's Hosp.

H. Burrows and O. A. L. Goode, having completed the final examination, are granted the diploma of the society entitling them to practise medicine, surgery, and midwifery.

Royal College of Surgeons of England

On Monday, March 2nd, Mr. C. E. Shattock will open the spring course of museum demonstrations at the Royal College of Surgeons by showing specimens illustrating cysts. On the following three Fridays Dr. A. J. E. Cave will deal with the anatomy of cervical rib and of certain vertebral joints and the significance of the facial musculature. Dr. L. W. Proger will demonstrate tumours of the kidney on Monday, March 16th, and on March 23rd new additions to the museum. The demonstrations will be held in the College, Lincoln's Inn-fields, London, W.C., at 5 p.m., and they are open to advanced students and medical practitioners.

University of Glasgow

It is announced that the number of students to be admitted to the first-year courses in medicine in October, 1936, will be limited and that forms of application for permission to commence the study of medicine, which may now be obtained from the registrar, must be returned by applicants not later than July 1st, 1936.

On the recommendation of the faculty of medicine the senate has resolved to add the subject of tropical diseases to the list of special departments from which a candidate may elect to be examined for the M.D. degree.

Post-graduate Course in Paris

A fortnight's course on the medical and hydrological treatment of digestive and nutritional disorders will begin on May 4th at the Hôpital Necker under the direction of Prof. Maurice Villaret. May 17th to 19th will be spent at Vichy where the last two lectures of the course will be given. Further information may be had from the Laboratoire d'Hydrologie et de Climatologie thérapeutiques, Faculté de Médecine, Paris.

British Institute of Philosophy

An address entitled *Vice and Illusion* will be given by Prof. Gilbert Murray on Tuesday, March 10th, at 8.15 p.m., at University College, Gower-street, London, W.C. Cards of admission may be had from the director of studies at University Hall, 14, Gordon-square, W.C.1.

Royal Sanitary Institute

A meeting of this institute will be held in the town hall, Ipswich, on Saturday, March 14th, at 2.30 p.m., when Mr. E. McLauchlan will open a discussion on the disposal of house refuse by controlled tipping, and Dr. A. M. N. Pringle a discussion on baths and bath water.

Public Food Service in Russia

At 8 p.m. on Thursday, March 12th, at the house of the Royal Society of Arts, 18, John-street, Adelphi, Mr. F. Le Gros Clark, hon. secretary of the Committee Against Malnutrition, will lecture on *Men, Medicine, and Food in the Soviet Union*. Tickets may be had from the committee at 19c, Eagle-street, London, W.C.1.

Microchemical Club

The third annual general meeting of this club will be held in the department of plant physiology at the Imperial College of Science and Technology, South Kensington, on Saturday, March 14th, at 11 a.m. The programme will include a lecture by Mr. C. Ainsworth Mitchell, D.Sc., on the microchemical examination of inks and handwriting.

Course in Psychological Medicine

The second part of the course of instruction for a diploma in psychological medicine, which has been arranged by the London County Council and is being held at the Maudsley Hospital, Denmark Hill, S.E., starts on March 2nd and will continue till May 25th. Further information may be had from Dr. F. Golla, hon. director of the medical school at the Maudsley Hospital.

Sir Charles Hastings Lecture

Prof. Winifred Cullis and Dr. R. Cove-Smith will deliver the eighth Sir Charles Hastings lecture at the house of the British Medical Association, Tavistock-square, London, W.C., on Tuesday, March 10th, at 8 p.m. Their subject will be *Keeping Fit*. Tickets may be had from the financial secretary of the B.M.A.

Demonstrations of Contraceptive Technique

On Thursday, March 5th, at 2.30 p.m., a practical demonstration of the technique of the use of a variety of contraceptive methods will be given by Mrs. Marie Stopes, D.Sc., and Dr. Evelyn Fisher at the clinic of the Society for Constructive Birth Control. Medical practitioners and senior students should apply for tickets to the hon. secretary of the society at the clinic, 108, Whitfield-street, London, W. 1.

A Debate on Euthanasia

At a meeting of the Law Students' Debating Society held in London on Feb. 18th Dr. C. Killick Millard, as a visitor, proposed "that in the interests of humanity it is desirable that voluntary euthanasia should be legalised, subject to adequate safeguards, for persons who are suffering from incurable, fatal and painful disease." Mr. A. L. Ungoed Thomas opposed the motion, and after discussion it was carried by one vote.

State Medical Faculty of Bengal

This faculty has instituted a fellowship examination (to be taken in medicine or surgery) for candidates who seek a post-graduate qualification equivalent in status to a university doctorate. Further particulars may be had from the secretary of the faculty at Grosvenor House, Calcutta.

Eugenics Society

At a meeting of this society to be held on Tuesday, March 17th, at 5.15 p.m., at the rooms of the Linnean Society, Burlington House, Piccadilly, London, W., Mr. D. Caradog Jones will speak on Eugenics and the Merseyside Enquiry. Mr. A. Bradford Hill, D.Sc., is to be in the chair.

British Postgraduate Medical School

On Mondays, at 2.30 p.m., beginning on March 2nd, Dr. Gordon Holmes, F.R.S., will give five lectures on cerebro-spinal syphilis, and on Fridays, at 5 p.m., beginning on March 20th, Sir James Walton will give six lectures on surgical aspects of dyspepsia. A course of 13 lectures on recent advances in obstetrics and infant hygiene (of which particulars will be found weekly in our Medical Diary) will be opened on Monday also, when Dr. Leonard Colebrook will discuss puerperal sepsis. Four lectures on the hygiene of the new-born child will be delivered by Dr. Alan Moncrieff from March 27th to April 24th. Further particulars of all these courses may be had from the Dean of the School, Duane-road, London, W. 12.

A Conference on Climatophysiology

The first All-Union Conference on Climatophysiology and Climatotherapy has recently been held in Moscow. "The problem of climate," said Prof. I. P. Razenkov, assistant director of the All-Union Institute of Experimental Medicine, in his opening speech, "is a vital problem of modern medicine. And in our country, with the great variety of climate in its different regions, these problems are of particular importance." A report by Prof. N. E. Marshak was devoted to the climatophysiological problems associated with the rapid industrial growth of the Soviet Union and the development and peopling of its borderlands, and also with the extensive use of climate in the prevention and cure of disease. The other communications presented to the Congress included observations on the climatic treatment of tuberculosis and of renal diseases, on physiological data obtained by the 1935 Pamir expedition, on climatotherapeutic research in Georgia, and on the effect of climatic conditions on treatment with ultra-violet rays.

Joint Tuberculosis Council

After discussing a number of present-day problems, including the new milk designations and the risk run in nursing tuberculous cases, the council lunched together on Feb. 22nd at the Hotel Russell, under the genial chairmanship of Dr. G. Lissant Cox. In replying for the guests, Dr. Arthur MacNalty said that the idea of having a council of all those interested was a great step forward in a national antituberculosis scheme. It was Dr. Ernest Ward's great idea and he was happy himself to have been the first representative of the Ministry of Health on the council, which had led to a better understanding of the aims and uses of the sanatorium-hospital and the place of after-care. The village settlement, he said, fully demonstrated the value of such work. Sir Henry Gauvain, in proposing The Council, excused himself from speaking to the toast in the phrase "we know we're all very good fellows and we needn't rub it in," and then told entertaining stories of his recent journey round the world. Dr. Ward, replying, recalled a M.O.H.'s remark to him, "Your work is easier than mine; it is static," and thus stimulated sought new fields of activity. The tuberculosis-rate was falling (not, it was true, as fast as in Italy), but had intensive pneumothorax treatment led to any acceleration in the fall? Some 10 per cent. of cases were infected from a known source; where did the remaining 90 per cent. get infected? In some cases where treatment was refused (but radiography permitted) he had watched the disease fade away; could the reason for this be discovered? Dr. C. O. Hawthorne proposed the health of the chairman.

THE King has granted permission to Colonel Philip Henry Mitchiner, T.D., M.S., surgeon to St. Thomas's Hospital, London, to wear the insignia of the second class of the Order of St. Sava, conferred on him by the King of Yugoslavia in recognition of his services.

Woolwich War Memorial Hospital

More accommodation is badly needed at this hospital, for the number of cases in every department was greater in 1935 than in 1934. There was a specially large increase in the number of out-patient attendances.

Ophthalmological Congress

The second Internationale Kongress für Irisdiagnostik, which was postponed last year, will be held on May 28th and 29th in Nuremberg. Further information may be had from J. Steen, Leubnitzerstr. 2, Dresden, A 24.

Chadwick Public Lectures

On Thursday, March 19th, at the Royal United Service Institution, Whitehall, London, S.W., at 5.30 p.m., Dr. Arthur MacNalty will give a public lecture under the auspices of this trust. He will speak on epidemic poliomyelitis and Sir James Crichton Browne, F.R.S., will be in the chair. On April 2nd, at 8.15 p.m., Mr. Lionel Pearson will speak on modern hospital construction at the Royal Institute of British Architects, 66, Portland-place, W. The lectures are open to all, and further particulars may be had from Mrs. Aubrey Richardson, O.B.E., at the offices of the trust, 204, Abbey House, Westminster.

Lectures on Women's Health

A series of lectures on this subject will be delivered under the auspices of the Royal Institute of Public Health and the Institute of Hygiene at 28, Portland-place, London, W., on Wednesdays, from March 4th to April 8th, at 3.30 p.m. The lecturers will be Mr. Aubrey Goodwin (the health of the married woman), Prof. Winifred Cullis (women in industry), Dr. G. W. Theobald (some effects of emancipation on the health of married women), Dr. J. F. Halls Dally (psychological influences on the circulation), Dr. R. Fortescue Fox (arthritis in women), and Prof. James Young (sociological problems affecting women's health). The lectures are open to all who are interested in health problems.

Appointments

- BRINTON, D., B.M. Oxon., M.R.C.P. Lond., has been appointed Neurologist to the Croydon General Hospital.
- CASE, R. M., M.B. Birm., Resident Medical Officer at the Leicester General Hospital.
- ELLIS, R. W. B., M.D. Camb., M.R.C.P. Lond., Physician to the Infants Hospital, Vincent-square, London.
- EVANS, C. D., M.B. Camb., Hon. Medical Registrar at the Royal United Hospital, Bath.
- GILPIN, A., M.D., M.R.C.P. Lond., Assistant Physician to the Croydon General Hospital.
- HARRIS, CHARLES, M.D., F.R.C.P. Lond., Physician to the Infants Hospital, Vincent-square, London.
- LAST, S. L., M.D. Berlin, L.R.C.S. Edin., D.P.M. Eng., Second Assistant Medical Officer at the Mental Hospital, Berry Wood, Northampton.
- MOORE, JOCELYN, M.B. Lond., F.R.C.S. Eng., M.C.O.G., Assistant Physician for Diseases of Women to the London Homeopathic Hospital.
- ROBERTS, L. V., M.B. Edin., Resident Medical Officer at the Leicester General Hospital.
- ROPER, R. D., M.B. Camb., Hon. Anaesthetist to Charing Cross Hospital.
- ROSENKRANZ, K., M.D. Freiburg, L.R.C.P. Edin., Assistant Radiologist at the Elizabeth Garrett Anderson Hospital.
- WHITTAKER, DUNCAN, M.R.C.S. Eng., Junior Assistant Physician at the Bethlem Royal Hospital.
- London Skin Hospital.*—The following appointments are announced:—
DUCKWORTH, GEOFFREY, M.R.C.P. Lond., Hon. Physician; MURRAY, J. F., M.B. Irel., Hon. Assistant Physician; and DUNN, J. H., M.D. Belf., M.R.C.P. Lond., Registrar.
- Southend General Hospital.*—The following appointments are announced:—
EVANS, WILLIAM, M.D., F.R.C.P. Lond., Hon. Physician; WHEELER, SIR WILLIAM, M.D. Dub., F.R.C.S. Irel., Hon. Surgeon; O'REILLY, J. N., B.M. Oxon., M.R.C.P. Lond., Hon. Physician in Diseases of Children; BARLOW, D. S., M.S. Lond., F.R.C.S. Eng., General Surgeon; BOND, L. T., M.B. Camb., Pathologist; and STRÖM-OLSEN, R., M.D. Wales, D.P.M., Hon. Psychiatrist.
- Certifying Surgeons under the Factory and Workshop Acts: Dr. J. O. McDONAGH (Stanley District, Perth) and Dr. N. ANDERMAN (Lynton District, Devon).

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, March 3rd.

Pathology. 8.15 for 8.30 P.M. (National Institute for Medical Research, Mount Vernon, N.W.). P. P. Laidlaw: 1. A Group of Filtrable Organisms. 2. An Anaerobic Method for Plates. W. J. Elford and M. Schlesinger: 3. Purified Preparations of Bacteriophage. F. F. Tang: 4. Filamentous Forms of Pleuropneumonia. C. H. Andrews: 5. Malignant Transformation of Virus-induced Papilloma of the Rabbit. 6. Immunisation of Mice against Influenza Virus. S. E. B. Balfour Jones: 7. Rat Leprosy in Hamsters. J. E. Barnard: 8. Microscopic Appearances of Some Viruses. P. Bruce White: 9. Polysaccharides from Cholera Vibrios. J. R. Perdrau: 10. Australian X-disease. A. S. Parkes and S. Zuckerman: 11. Changes in the Primate Prostate Caused by Estrone and their Suppression by Male Hormone.

Orthopaedics. 8.30 P.M. Mr. George Perkins and Mr. R. Watson Jones: Fractures in the Region of the Shoulder-joint.

WEDNESDAY.

History of Medicine. 5 P.M. Prof. Millais Culpin: The History of Psychology in Medicine.

Surgery. 8.30 P.M. Mr. Ian Aird, Mr. G. C. Knight, Mr. David Slome, and Mr. R. St. Leger Brockman: Intestinal Strangulation.

THURSDAY.

Tropical Diseases and Parasitology. 8 P.M., Special Meeting. 8.30 P.M., Colonel S. P. James: Clinical and Parasitological Observations Applicable to the Study of Malaria Epidemics.

FRIDAY.

Otology. 10.30 A.M. (Cases at 9.30 A.M.) Dr. G. Kelemen (Budapest) and Dr. E. A. Blake Pritchard: Disturbances of Function of the Ear following Injury.

Laryngology. 5 P.M. (Cases at 4 P.M.) Dr. A. Brown Kelly, Dr. G. Kelemen, Mr. V. E. Negus, and Mr. G. H. Steele: Non-malignant Obstruction of the Oesophagus.

Anaesthetics. 8.30 P.M., Clinical Meeting.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.

MONDAY, March 2nd.—9 P.M., Dr. P. H. Manson-Bahr: The Differential Diagnosis of Diseases of the Colon (Dysentery and Colitis) and their Complications, with Special Reference to Treatment (last Lettsomian lecture).

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, March 6th.—8.45 P.M. (West London Hospital), Clinical and Pathological Meeting. (Cases at 8 P.M.)

SOCIETY OF CHEMICAL INDUSTRY (London Section).

MONDAY, March 2nd.—8 P.M. (Burlington House, Piccadilly, W.), Dr. T. A. Henry: The Chemotherapy of Malaria.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, March 3rd.—5 P.M., Dr. E. L. Middleton: Industrial Pulmonary Disease due to the Inhalation of Dust, with Special Reference to Silicosis (last Milroy lecture).

THURSDAY.—5 P.M., Dr. R. A. McCance: Medical Problems in Mineral Metabolism (first Goulstonian lecture).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.

MONDAY, March 2nd.—5 P.M., Mr. C. E. Shattock: Specimens Illustrating Cysts.

FRIDAY.—5 P.M., Dr. A. J. E. Cave: The Anatomy of Cervical Rib (Museum demonstrations).

UNIVERSITY OF LONDON.

MONDAY, March 2nd.—5 P.M. (University College, Gower-street, W.C.), Dr. Charles Reid: The Endocrine Organs in Relation to Metabolism (first of four lectures).

TUESDAY.—5 P.M., Dr. R. Kuczynski: Recent Population Trends (first of three lectures).

INSTITUTE OF HYGIENE, 28, Portland-place, W.

WEDNESDAY, March 4th.—3.30 P.M., Mr. Aubrey Goodwin: The Health of the Married Woman.

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.

MONDAY, March 2nd.—2.30 P.M., Dr. Gordon Holmes, F.R.S.: Cerebro-spinal Syphilis (first of five lectures). 3.30 P.M., Dr. Leonard Colebrook: Puerperal Sepsis.

WEDNESDAY.—3.30 P.M., Mr. Eardley Holland: Haemorrhage of Late Pregnancy.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.6.

MONDAY, March 2nd.—10 A.M., Skin clinic. 11 A.M., Surgical wards. 2 P.M., Gynaecological and surgical wards, gynaecological and eye clinics.

TUESDAY.—10 A.M., Medical wards. 11 A.M., Surgical wards. 2 P.M., Throat clinic.

WEDNESDAY.—10 A.M., Children's ward and clinic. 11 A.M., Medical wards. 2 P.M., Eye clinic, gynaecological operations.

THURSDAY.—10 A.M., Neurological and gynaecological clinics. Noon, Fracture clinic. 2 P.M., Eye and genitourinary clinics. 4 P.M., Venereal diseases.

FRIDAY.—10 A.M., Medical wards and skin clinic. Noon, Lecture on treatment. 2 P.M., Throat clinic. 4.15 P.M., Mr. Vlasto: Haemorrhage from the Upper Respiratory Tract.

SATURDAY.—10 A.M., Children's and surgical clinics, Medical wards.

Daily, 2 P.M., Operations, Medical and Surgical Clinics. The lectures at 4.15 P.M. are open to all medical practitioners without fee.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

WEDNESDAY, March 4th.—2 P.M., Dr. B. E. Schlesinger: Croup. 3 P.M., Dr. D. N. Nabarro: Purity of Milk-supply.

Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, March 2nd.—3.30 P.M., Dr. Kinnier Wilson: Some Heredo-familial Diseases (IV.) Cerebellar Spinal.

TUESDAY.—3.30 P.M., Mr. Julian Taylor: Spinal Compression.

WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.

THURSDAY.—3.30 P.M., Mr. Leslie Paton: Optic Atrophy.

FRIDAY.—3.30 P.M., Dr. Purdon Martin: Disseminated Sclerosis.

Out-patient clinic daily at 2 P.M.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W.

TUESDAY, March 3rd.—5.30 P.M., Dr. J. M. H. Campbell: The Use of Quinidine in Fibrillation.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL, N.W.

WEDNESDAY, March 4th.—4 P.M., Dr. Ralph Noble: Some Psychological Principles in General Medicine.

ST. JOHN CLINIC, Ranelagh-road, S.W.

FRIDAY, March 6th.—4.30 P.M., Mr. H. J. Taylor, Ph.D.: The Physical Basis of Electric Treatments, including Diathermy and Ultra-short Waves.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION.

WEDNESDAY, March 4th.—4 P.M. (St. James's Hospital, Ouseley-road, S.W.), Mr. V. Z. Cope: Demonstration of Surgical Cases.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, March 2nd, to SATURDAY, March 7th.—INFANTS HOSPITAL, Vincent-square, S.W. Mon., Wed., and Fri., at 8 P.M., primary F.R.C.S. course in anatomy and physiology.—NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W. Tues., 8.30 P.M., Mr. Hamilton Bailey: Testicle and Prostate. Thurs., 8.30 P.M., Mr. T. Meyrick Thomas: Breast (M.R.C.P. clinical course at 8 P.M.).—WEST END HOSPITAL FOR NERVOUS DISEASES, Welbeck-street and Regent's Park.—Afternoon M.R.C.P. course in neurology and psychopathology.—BROMPTON HOSPITAL, S.W.—Week-end course in chest diseases.—Courses are open only to members of the Fellowship.

MANCHESTER ROYAL INFIRMARY.

TUESDAY, March 3rd.—4.15 P.M., Mr. P. R. Wrigley: Chronic Abdominal Pain.

FRIDAY.—4.15 P.M., Mr. A. Graham Bryce: Demonstration of Surgical Cases.

ANCOATS HOSPITAL, Manchester.

THURSDAY, March 5th.—4.15 P.M., Mr. E. S. Brentnall: Fractures of the Spine.

LEEDS GENERAL INFIRMARY.

TUESDAY, March 3rd.—3.30 P.M., Mr. Armitage: (1) Injection Therapy in the Treatment of Hemorrhoids and Varicose Veins. (2) Demonstration of Some Surgical Cases.

LEEDS PUBLIC DISPENSARY.

TUESDAY, March 4th.—4 P.M., Dr. H. G. Garland: Neuritis—the Common Causes, Prognosis, and Treatment.

UNIVERSITY OF DURHAM.

SUNDAY, March 8th.—10.30 A.M. (Newcastle General Hospital), Dr. W. G. A. Swan: Selected Medical Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, March 4th.—4.15 P.M. (Western Infirmary), Dr. John Gracie: Nephritis.

CONGRESS OF COMPARATIVE MEDICINE.—The third International Congress of Comparative Medicine will take place in Athens from April 15th to 18th under the presidency of Prof. W. Bensis. The last meeting of the congress will be held at Epidaurus. Twenty-eight nations, including Great Britain, will be officially represented, and a British committee is being formed under the chairmanship of Lord Dawson. The official representatives of the British Government are: Mr. F. P. Brooks, F.R.S., Dr. N. Hamilton Fairley, and Prof. F. C. Minett, and those contributing to the proceedings will include Lieut.-Colonel H. E. Short. Further information can be had from the secretary of the British committee, Dr. A. P. Cawadiaz, 52, Wimpole-street, London, W.1.

NOTES, COMMENTS, AND ABSTRACTS

PASTEURISING PLANTS

THE apparent failure of pasteurisation of milk between 145° and 150° F. for 30 minutes to destroy tubercle bacilli has been recorded by various investigators.¹ Since others have obtained consistently negative results when examining milk from efficiently designed and operated pasteurising plants under the same conditions of time and temperature, it seems likely that failure to destroy the tubercle bacilli is an indication of a bad design or inexpert operation of the apparatus. In order to test this hypothesis A. W. Scott and N. C. Wright have examined 19 holding plants in 4 Scottish cities. The outcome of their investigations is set out in a special report to the Hannah Dairy Research Institute.² Some of the conclusions reached are summarised below.

Filtration.—Milk is usually weighed at a platform and then transferred into a receiving tank after passing through a coarse filter designed to remove large particles. Such filters should not be constructed of copper for fear of tainting the milk. The receiving tank should be sufficiently large in relation to the capacity of the rest of the plant to ensure a steady, unbroken supply of milk into the heating apparatus throughout the run. Milk is generally circulated by means of force pumps. Pumps having a long suction lead are undesirable owing to the danger of air leaks developing at joints and consequent contamination of milk from the air. Nor is it desirable to pass milk through a pump after pasteurisation owing to the danger of contamination from the working parts of the machine. Milk should flow by gravity through the cooling and bottling apparatus. Careful filtration or clarification of milk prior to pasteurisation is most necessary. For this purpose cloth filters or centrifugal separators may be used. There is no agreement as to which constitutes the more satisfactory type, but whichever method of cleansing is used it should be carried out at as low a temperature as possible so as not to interfere with the cream-line of the resulting product.

Milk may be pre-heated to the requisite temperature and then passed into holding tanks, or it may receive all the heating in the holder. Four types of *heating apparatus* were examined—viz., kettle heaters, plate heaters, tubular heaters, and batch pasteurisers. The first three types depend upon the rapid passage of a thin layer of milk through a narrow space with suitably heated walls. In the batch pasteuriser a vat of milk is heated by a steam jacket, circulation being assisted by rotary paddles, or by rotating heated coils. The heating of the walls in the first three types—i.e., the pre-heaters—is effected by a system of jacketing with hot water or with steam. If circulating hot water is used, and provided the temperature of the water is thermostatically controlled, these types of pre-heaters raise the milk to an extremely constant temperature. Where tanks are heated directly automatic thermographs should be installed.

As regards *holding tanks* to which milk is passed following "pre-heating," their object is to retain the milk at a temperature between 145° and 150° F. for a minimum of 30 minutes. A single tank is generally used for this purpose which is jacketed with steam or hot water. Provided that the correct temperature is maintained in the main bulk of the milk throughout the run, survival of tubercle bacilli can generally be explained by the existence of dead spaces, faults in the inlet or outlet valves, poor mixing, or excessive foam formation. A dead space is a portion of the milk where circulation is suppressed and which does not reach the required temperature. Such spaces are generally associated with leads to the valves and can be avoided by fitting such valves

flush with the sides of the tank. The valves themselves should not leak; or any milk which leaks must be allowed to run to waste. Adequate stirring of the milk is necessary, but foam formation must be avoided, whilst measures should be taken to avoid contaminating milk with grease or dirt from the bearings of the stirring paddles. Where foam is formed tubercle bacilli and thermophilic organisms may escape destruction through not being sufficiently heated in the protecting foam; formation of this foam can be avoided by a suitable design of the inlet valve and the stirring apparatus, or else the space above the milk in the holder must be adequately heated, in which case foam formation ceases to matter. It was found that thermometers and thermographs used in the various plants showed striking errors of reading, which emphasises the need for frequent checking of such instruments against standard thermometers. In order to ensure constant temperatures all heating processes should be thermostatically controlled, whilst the holder tank should be fitted with a thermograph and a direct reading maximum and minimum thermometer. As regards the duration of heating, it is emphasised that the regulations demand that all milk shall be held at the required temperature for a minimum period of 30 minutes *exclusive* of the time taken to fill and to empty the holder.

Two types of *cooling apparatus* were studied, the one where milk trickles over the surface of corrugated plates cooled by a brine jacket and is exposed to the atmosphere, the other in which the milk is cooled internally. Both types cooled the milk satisfactorily, and the contact between the atmosphere and the milk in the first type had less influence upon the bacterial content of the finished product than might have been expected. The important consideration is the adequate cleansing of the apparatus. To avoid contamination of milk with organisms pathogenic to human beings an internal cooling system is desirable. As regards the bottling apparatus, the design of the apparatus is of secondary importance compared to the necessity of adequate cleansing. An obvious corollary to this point is that the apparatus, and in particular the delivery valves, should be designed with a view to easy cleansing. This remark applies to every piece of apparatus and every pipe through which the milk is passed.

In judging the *suitability of milk* received for pasteurisation, attention should be paid not only to the pre-pasteurisation bacterial count, since that is frequently an unfair index of the conditions under which the milk has been produced, but also to the post-pasteurisation count of heat resistant organisms. The former count is largely influenced by weather conditions, but the thermophilic organisms come from dust and from badly sterilised apparatus, so that a high count of these organisms indicate strongly that the hygiene of production has been bad.

It is suggested that the dairy firms would do well to carry out *routine bacterial examinations* of milk after every stage of pasteurisation, for such a procedure would give a reliable check of the efficiency with which the apparatus was functioning. Furthermore, routine examinations should be made by an outside authority in order to create a standard by which the efficiency of pasteurisation may be judged, and in order to give independent evidence of the efficiency of operation of any particular plant. Also it would serve to deter plant operators from becoming careless. In addition to bacterial counts, an estimation of the *coli* content of milk is a useful index of efficiency of pasteurisation. But quite irrespective of such tests the adequacy of plants must finally be judged by their ability or otherwise to destroy tubercle bacilli, since that is the primary function of pasteurisation. It is of interest to note that Scott and Wright found that out of 332 samples of milk taken from 3 plants run in a slipshod manner,

¹ Medical Research Council, Special Report Series No. 189.

² Hannah Dairy Research Institute, 1935, Bull. No. 6, pp. 72.

3.3 per cent. contained tubercle bacilli. Out of 340 samples taken from 4 efficiently operated plants, none were found to contain this organism.

PHYSIOLOGY FOR SCHOOLBOYS

A SMALL book,¹ to which Sir Humphry Rolleston and Dr. J. R. Rees have written complimentary forewords, embodies a course of seven lectures primarily intended for public schoolboys. The first four lectures deal with the digestive, circulatory, respiratory, and skeletal systems. Consideration of the nervous system is divided between the fourth and fifth lectures and the latter also includes the urogenital system. The sixth lecture summarises what has gone before and the seventh lecture, reserved for those of leaving-age, discusses venereal disease. The facts are accurate and the treatment not too profound. The style is attractively simple and intimate. Dr. Barber perhaps dwells too much on the dangers of constipation and, in a laudable anxiety not to stress sex unduly, has possibly erred on the other side. Some concrete amplification as to how the sex-impulse is to be sublimated before marriage is economically possible might not have been out of place. This little work should be in the hands of all schoolmasters, parents, and school medical officers. With certain modifications, it should be equally useful to headmistresses and those who have charge of the adolescent girl.

A VISIT TO THE G.P.O.

IN no business is efficiency as necessary for the comfort and smooth running of private and business life as it is in the General Post Office. How this high standard is maintained was shown when the Postmaster-General entertained the London University Medical Graduates Society on Feb. 21st in the King George V. Hall of the Central Telegraph Office. After welcoming the guests, he invited them to visit what he claimed to be the largest and most efficient business organisation in the country. To the medical profession, he said, the health service under Dr. H. H. Bashford would be of particular interest, especially on account of the complete and accurate records kept of the staff of over 240,000, of all ages from 16 to 60. The recent great advances in the Post Office routine kept abreast of the times in response to the need of the general public for simplicity and of the modern business world for speed and efficiency. Examples were, on the one hand, the sixpenny telegram and the single night charge for all telephone calls throughout the country; and, on the other, the development of continental and trans-atlantic telephony, the "telex" system where typescript would be transmitted and received in the same way as conversation in the ordinary telephone, and, for the press, picture telegraphy. Mr. W. McAdam Eccles, in expressing the thanks of the company, claimed to be one of the first in Harley-street to use the telephone, and he described its value at that time in a surgical emergency in the country.

The guests were then divided into groups to visit the chief departments of the Post Office. One party was conveyed to Mount Pleasant, the headquarters of the inland sorting office and of the unique underground postal railway. A second group stayed in the Central Telegraph Office, which also housed the medical department and the new air-conditioned King George V. Hall, used for exhibitions, broadcasting, lectures, and cinema displays. The apparatus and transmission of picture and ordinary telegraphy were demonstrated, as well as the use of underground tubes, of which there are 75 miles under the London streets connecting the main post offices and business houses, and of the telephone, both of which have done much to accelerate telegraphy. The two remaining parties were shown the overseas mail

department and the international telephone exchange; telephonic communication took place during the time of the visit with places as far apart as Cape Town, Sydney, Bombay, New York, and the *Aquitania* in mid Atlantic.

A HOME FOR TUBERCULOUS NURSES

Miss K. L. Borne, Matron of Papworth Village Settlement, Cambridge, writes: "Papworth proposes to build a special home for the benefit and prolonged after-care of nurses who have contracted tuberculosis in the course of their duties. This scheme ought to meet with the approval of members of the medical profession who know how difficult it is to advise an ex-sanatorium nurse regarding her future and her means of livelihood. At Papworth work will be available, either as a nurse or in some other suitable occupation. Since 1930 we have found it possible to employ many ex-patient nurses in the wards or in the Papworth Industries. We have discovered that, given shorter hours and sanatorium conditions, under medical supervision, such patients have become partially, some wholly, self-supporting. It is to give a larger number of nurses this same opportunity that I am venturing to ask assistance from the medical profession in the form of a small contribution towards the cost of building this house for 40 ex-sanatorium nurses, or a donation to the Endowment Fund. If every member of the medical profession would send me 5s. we could, I think, pay for the house and still have something over towards endowing a few beds for nurses who are no longer able to work at all, and whose future is grey. The house has been designed by Mr. H. H. Dunn, F.R.I.B.A., our honorary architect, and will be built by the Papworth Industries, thus providing employment for other ex-patients at Papworth. Its site will be near our Nurses' Home, in beautiful surroundings, with a garden, and will contain 40 bedrooms and dining- and sitting-rooms. The cost is expected to be less than £20,000."

PHYSIOLOGY OF LACTATION

THE physiology of milk secretion in the cow is being studied by Prof. H. D. Kay, of the National Institute for Research in Dairying, and his co-workers, and some of the findings were communicated to the Royal Society last Thursday. A new technique has been devised for obtaining arterial blood without serious disturbance to the animal, and with this method it has been ascertained that: (1) the fat of cow's milk is derived mainly from the non-phospholipin fatty acids of the blood; (2) the phosphorus compounds of the milk (including casein) derive their phosphate from the *inorganic* phosphate of the blood plasma; (3) relatively large quantities (up to 30 per cent.) of the blood-sugar are removed from the blood on passage through the mammary gland, the amount of sugar taken out of unit volume of blood being related to the level of sugar in the arterial blood and (probably) to the volume of milk secreted; and (4) the number of volumes of blood required to produce one volume of milk is of the same order whether calculated from the fatty acid changes, inorganic phosphate changes, or sugar changes between arterial and venous blood. A rapid circulation of blood—probably at the rate of 300–400 volumes for each volume of milk secreted—takes place through the mammary tissue.

The suggestion has been made that one of the factors controlling the quantity and quality of the milk secreted is the arterial blood-sugar level. This can be raised and kept above the normal level in the cow by thyroid feeding or thyroxine administration, and under proper conditions, it is found, thyroxine produces a considerable increase in milk volume and in milk fat percentage and also in the percentage of non-fatty solids in the milk. After cessation of thyroxine treatment, the rate of milk secretion rapidly falls and may go below the normal rate that would be expected from the slope of the lactation curve. Thyroxine does not, however, prevent the normal

¹ School Education in Hygiene and Sex. By G. O. Barber, M.B., B.Chir., M.R.C.S., L.R.C.P., Medical Officer, Felsted School. Cambridge: W. Heffer and Sons, Ltd. 1936. Pp. 71. 2s. 6d.

progress of the diminution of functional activity of the mammary gland (which normally takes place after the peak of the lactation cycle): the "thyroxine curve" is parallel with the "normal" one but at a considerably higher level.

During these investigations the phosphatase content of the milk (but not of the blood plasma) of the thyroxine-treated animals showed a striking decrease, which was more than restored when thyroxine administration was stopped. The phosphatase of the milk, it is concluded, is not derived directly from that of the blood.

Messrs. DOWN BROS., LTD. (London, S.E. 1), have been awarded the medal of the exhibition held at Cairo last month in connexion with the tenth International Congress of Surgery. They displayed surgical instruments and theatre equipment.

Vacancies

Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.
 Aylesbury, Bucks, Mental Hospital, Stone.—Sen. Asst. M.O. £600. Also two Jun. Asst. M.O.'s. Each £350.
 Bath Royal United Hospital.—H.S. At rate of £150.
 Belfast, Royal Maternity Hospital.—Res. H.S. At rate of £100.
 Benenden, Kent, National Sanatorium.—Jun. H.P. At rate of £150.
 Birmingham City.—Asst. M.O. for Maternity and Child Welfare. £500.
 Birmingham, Queen's Hospital.—Res. Surg. Reg. £125. Also Sen. Res. Anaesthetist. £70-£100.
 Brighton, Royal Sussex County Hospital, and Hove General Hospital.—Hon. Physiotherapist. Also Hon. Med. Reg.
 Bristol University.—Asst. Clin. Path. £375.
 Cardiff, Welsh National Memorial Association.—H.P. for Adeline Patti Hospital. At rate of £150.
 Charderton, U.D.—M.O.H., &c. £800.
 Chester, County Mental Hospital.—Jun. Asst. M.O. £350.
 City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Physician to In-patients.
 Colonial Medical Service.—Twenty-five Vacancies. Each £600-£700.
 Dewsbury and District General Hospital.—Second H.S. £150.
 Dreadnought Hospital, Greenwich, S.E.—H.P. and H.S. Each at rate of £110.
 Dublin, Peamoun Sanatorium, Newcastle.—Asst. Med. Supt. £300.
 Dudley, Guest Hospital.—H.S. £200.
 Dundee Corporation.—P.H. Dept. Asst. M.O.H. £600.
 Edinburgh, National Association for the Prevention of Tuberculosis.—Secretary-General. £600.
 Exeter, Royal Devon and Exeter Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.
 Gloucestershire Royal Infirmary.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.
 Golden-square Throat, Nose, and Ear Hospital, W.—H.S. £100.
 Gordon Hospital for Rectal Diseases, Vauxhall Bridge-road, S.W.—Res. H.S. At rate of £150.
 Guildford, Royal Surrey County Hospital.—H.S. Also H.P. and Cas. O. Each at rate of £150.
 Hamstead General and N.W. London Hospital, Haverstock Hill, N.W.—Cas. M.O. for Out-patient Dept. At rate of £100.
 Harrogate and District General Hospital.—H.P. and Cas. O. Also H.S. Each at rate of £150.
 Hertford County Hospital.—Hon. Clin. Asst. Hospital for Sick Children, Great Ormond-street, W.C.—Res. H.P. and Res. H.S. Each at rate of £100.
 Hospital for Tropical Diseases, Gordon-street, W.C.—H.P. At rate of £120.
 Hove General Hospital.—Hon. Medical Officer.
 Huddersfield Royal Infirmary.—Cas. O. £200. Also H.S. At rate of £150.
 Kennington Royal Borough.—Asst. M.O. £500.
 Kesteven County Council.—M.O.H. £1000.
 Lancashire County Council.—Asst. Med. Supt. for High Carley Sanatorium. £450. Also Jun. Asst. M.O. for Wrightington Hospital. £200.
 Leamington Spa, Warnford General Hospital.—Res. H.S. to Cas. and Spec. Depts. At rate of £150.
 Leicester Royal Infirmary.—Res. Anaesthetist. At rate of £150.
 Cas. O., H.S., and H.P.'s. Each at rate of £125. Also Jun. Cas. O. At rate of £100.
 Liverpool, City Infectious Diseases Hospitals.—Asst. Res. M.O. £200.
 Liverpool, Hospital for Consumption and Diseases of the Chest, Mount Pleasant.—Res. M.O. £150.
 Liverpool, Ministry of Pensions Hospital, Mossley Hill.—Visiting Surgeon. £300.
 London County Council.—Temp. District M.O. At rate of £290.
 London Homoeopathic Hospital, Great Ormond-street, W.C.—H.P. At rate of £100.
 Macclesfield General Infirmary.—Second H.S. At rate of £150.
 Maidstone, County Pathological Laboratory.—Asst. Pathologist. £700.
 Maidstone, West Kent General Hospital.—H.P. £175.
 Manchester, Crumpsall Hospital and Institution.—Jun. Asst. M.O. At rate of £200.

Manchester Royal Children's Hospital, Garside-street.—Two Asst. M.O.'s. Each at rate of £150.
 Manchester Royal Eye Hospital.—Jun. H.S. £120.
 Manchester Royal Infirmary.—Jun. Asst. M.O. for Radiological Dept. £350.
 Manchester, St. Mary's Hospital.—Four H.S.'s. Each at rate of £50.
 Manchester, Withington Hospital and Institution.—Asst. M.O. for Tuberculosis Wards. At rate of £300.
 Melton, Suffolk, St. Audry's Hospital.—Jun. Asst. M.O. £350.
 Middlesex County Council.—Asst. M.O. £600.
 Northampton General Hospital.—H.P., H.S.'s, also Cas. O. Each at rate of £150.
 Norwich, Norfolk and Norwich Hospital.—Res. Surg. O. £250. Also Res. Orthopaedic O. £200.
 Nottingham General Hospital.—H.S. for Fracture and Orthopaedic Depts. £300. Also H.S. to Ear, Nose, and Throat Dept. At rate of £150.
 Plymouth City General Hospital.—Jun. Asst. M.O. £250.
 Preston, Sharoe Green Hospital.—Sen. and Jun. Asst. Res. M.O.'s. At rate of £200 and £100 respectively.
 Prince of Wales's General Hospital, N.—Hon. Med. and Surg. Regs. Each £100.
 Princess Elizabeth of York Hospital for Children, Shadwell, E.—H.P. At rate of £125.
 Princess Louise Kensington Hospital for Children, St. Quintin-avenue, W.—H.S. At rate of £100.
 Reading County Borough.—Asst. M.O.H. and Asst. School M.O. £500.
 Rochdale, Birch Hill Hospital.—Jun. Res. M.O. At rate of £200.
 Rochdale Infirmary and Dispensary.—Second H.S. £150.
 Romford Isolation Hospital.—Res. Asst. M.O. £350.
 Rotherham Hospital.—Cas. H.S. £150.
 Royal Eye Hospital, St. George's-circus, S.E.—Part-time Pathologist and part-time Bacteriologist. Each £100. Also Sen. H.S. and two Asst. H.S.'s. At rate of £150 and £100 respectively.
 Royal Masonic Hospital, Ravenscourt Park, W.—Res. Surg. O. At rate of £250.
 Royal National Orthopaedic Hospital, 234, Great Portland-street, W.—H.S. At rate of £150.
 St. John's Hospital, Lewisham, S.E.—Hon. Anaesthetist to Ear, Nose, and Throat Dept.
 St. Peter's Hospital for Stone, &c., Henrietta-street, W.C.—H.S. At rate of £75.
 Salford Royal Hospital.—H.P., H.S., and Cas. H.S. Each at rate of £125. Also Hon. Asst. Gynecologist.
 Scarborough Hospital and Dispensary.—Two H.S.'s. Each £175.
 Sheffield, Jessop Hospital for Women.—Res. M.O. Also two H.S.'s. At rate of £150 and £100 respectively.
 Shoreham-by-Sea, Southlands Hospital.—Part-time Radiologist. £100.
 South Shields, Ingham Infirmary.—Jun. H.S. £150.
 Stoke-on-Trent, North Staffordshire Royal Infirmary.—Radium Officer. £500.
 Sunderland Royal Infirmary.—H.S. £120.

Births, Marriages, and Deaths

BIRTHS

BACH.—On Feb. 18th, 1936, at 20, Devonshire-place, W.1, to Matine (née Thompson), wife of Francis Bach, M.D., of 49, Wimpole-street, W.1—a son.
 CHAMBERS.—On Feb. 16th, at Ealing Common, W., the wife of Dr. J. R. Chambers, of a daughter.
 MOCKLER.—On Feb. 18th, at Welbeck-street, W., the wife of Surg. Lt.-Comdr. E. J. Mockler, M.B. N.U.I., Royal Navy, of a son.

MARRIAGES

ENRAGHT—SHEPHERD.—On Feb. 20th, William Enraght, M.R.C.S. Eng., Croydon-road, S.E., to Jessie Gray, youngest daughter of the late Mr. and Mrs. T. A. Shepherd.
 REECE—PETRIE.—On Feb. 15th, at St. James's, Piccadilly, Richard Harold Reece, M.A. Camb., M.R.C.S., to Janet Anderson Petrie, B.Sc., only daughter of Mr. and Mrs. John A. Petrie of Glasgow.

DEATHS

DUNLOP.—On Feb. 19th, at Norbrook, Knock, Co. Down, Joseph Everard Dunlop, M.D. R.U.I.
 PRUEN.—On Feb. 19th, Septimus Tristram Pruen, M.D. Durh., of Cheltenham, aged 76.
 UNDERHILL.—On Feb. 17th, at Vancouver, Frederic Theodore Underhill, F.R.C.S. Edin., son of the late Dr. William Lees Underhill, Tipton, Staffordshire.
 WILSON.—On Feb. 19th, James Alexander Wilson, O.B.E., M.D. Glasg., of Cambuslang, Lanarkshire.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

SOME OBSERVATIONS ON
PEPTIC ULCER*

BY DANIEL T. DAVIES, M.D. Wales, F.R.C.P. Lond.
ASSISTANT PHYSICIAN TO THE ROYAL FREE HOSPITAL,
LONDON

PEPTIC ulcer is in some respects a modern disorder, for it is unknown in the primitive uncivilised races, and equally unknown in the animal kingdom. It attacks the young adult rather than the old, the thin rather than the fat, and males more frequently than females. It is a common source of ill-health in city dwellers, and more often in those who carry responsibilities and their attendant anxieties. Moreover, there is a constitutional type which is prone to develop the disorder, the doer rather than the dreamer, the active in body and mind rather than the lethargic and more contented. It is not surprising, therefore, that its incidence is on the increase. The Registrar-General's statistics show that the number of deaths from ulcer has risen steadily during the past ten years (Table I.), and since the mortality is relatively low, we can assume that the number actually suffering from the disorder is also steadily rising.

Experimental and Pathological Data

Before proceeding to the more clinical aspect of this problem, brief reference should be made to work which has been done on animals. For many years attempts to produce a "chronic" ulcer met with no success, but during recent years this has been accomplished, largely through the work of American experimental surgeons, notably Mann,¹ Ivy,² Matthews and Dragstedt,³ and Morton.⁴ Mann and Williamson⁵ were the first to develop a technique of diverting the alkaline duodenal juices and demonstrate that an ulcer would form in the intestine distal to the anastomosis, although it appears that Exalto⁶ in 1911 was the pioneer.

If the intestine is anastomosed to the stomach, and the duodenum with its alkaline juices allowed to drain into the lower part of the intestine, an ulcer readily forms at the site where the gastric juice first impinges on the intestinal mucosa. It develops with great rapidity, for according to Mann and Bollman⁷ penetration of the mucosa only needs a few hours and perforation into the abdominal cavity can occur within the first 48 hours. The typical "chronic" ulcer forms within 3-4 weeks, and histologically this is identical with that seen in man. Furthermore, its presence, like that of the human ulcer, is heralded by such events as perforation or melæna.

Not only does this experimental ulcer form readily, but it equally readily disappears. Provided the acid juice is made to impinge on an adjoining part of the

intestinal mucosa, the original ulcer begins to heal, and within 30 days healing is often complete. Mann draws attention to the delicacy of the repair tissue, and the ease with which it can be broken down again by coarse food or an acid juice. The mucosa readily regenerates, but if the muscle has been involved in the ulcerative process it is replaced by scar tissue only.

Matthews and Dragstedt's technique³ is particularly instructive in demonstrating the essential action of the gastric juice (Fig. 1). By suturing the jejunum or ileum on to a

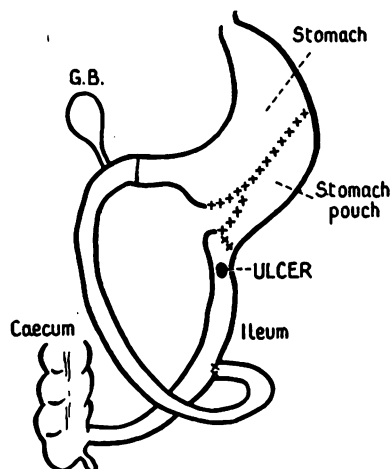

FIG. 1.—Matthews and Dragstedt's experiment.
G.B. = gall-bladder.

gastric pouch, and thereby allowing the intestinal mucosa to be bathed with a highly concentrated acid juice, ulcers could be produced with regularity—"a striking example of the susceptibility of an organism's living tissues to the irritant action of its own pure active gastric juice." It was also demonstrated by these workers that if the gastric juice was deliberately retained in this pouch by plugging the stoma, an ulcer formed in the pouch itself. The implantation of a portion of intestinal wall into the stomach does not result in ulcer formation (Dragstedt and Vaughan⁸), but if a small gastric pouch is implanted into the intestine, ulcer formation is the rule. In the latter experiment the intestinal mucosa is exposed to the pure active juice undiluted with food, while in the former experiment the gastric juice is already diluted and buffered by food and saliva and its action weakened in consequence.

These experiments prove that under certain conditions normal gastric juice is by itself capable of producing a chronic ulcer in the intestine. The commonest seat of ulcer in man is the first part of the duodenum, and here, as Mann and Bollman state, "is the site where the onrushes of acidity produced in the fundus are met, diluted, neutralised and buffered for acceptance by the intestine." Under normal conditions the acidity of the duodenal contents fluctuates between a pH of 2 and 7, but the jejunal contents maintain a steadier reaction between a pH of 6.2 and 8.2 (Wu, quoted by Mann and Bollman⁹). When the jejunum is anastomosed to the stomach the jejunal contents are then found to fluctuate between a reaction of pH 1.7 and 8.33, under which condition we know that jejunal ulceration would be possible. Corroborative evidence of the importance of acid in ulcer development is the observation, again made by Mann, that repeated administration of acid does eventually result in an ulcer of the stomach itself.

Methods to produce partial pyloric stenosis have been shown to result in increased acidity,^{10 11} and Bolton¹² in 1909 demonstrated the slow healing of traumatic ulcers under such conditions. Not only

* The Bradshaw lecture for 1935, delivered before the Royal College of Physicians of London on Nov. 5th.
5871

does the acidity rise in partial pyloric stenosis, experimentally produced, but the spontaneous perforation of a duodenal ulcer has been recorded as a sequel to this (Elman and Eckert¹³; Ham-

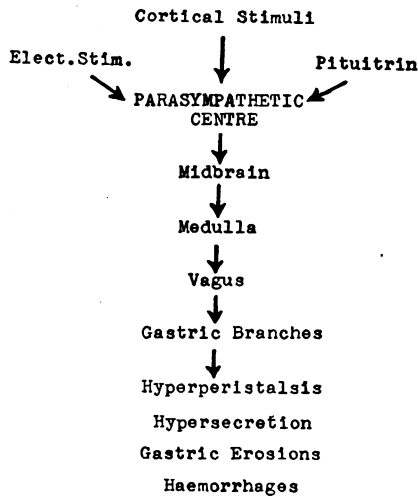

FIG. 2.—Diagrammatic representation of nervous pathways (after Cushing).

From these observations we are quite justified in concluding that the experimentally produced chronic peptic ulcer is dependent on an acid gastric juice for its development, and that an acid juice, provided it is undiluted, is sufficient for the development of the ulcer in the intestine. When we recall that the commonest seat of ulcer is in the duodenum, this knowledge derived from animal experiments becomes highly significant. We also learn that the ulcer forms with rapidity and likewise is rapid in healing. Whatever view is held regarding the aetiology of ulcer in man, due cognizance must be given to this eroding action of the gastric juice. Is it possible that clinical ulcers as readily heal and break down again? The coexistence of achlorhydria and ulcer would certainly be difficult to explain, and any treat-

FIG. 4.—Large ulcer crater in a man of 64 with an eight weeks' history.

ment which does not allow for adequate neutralisation of the acid juice would not enjoy experimental support.

THE NERVOUS FACTOR

Some three years ago Harvey Cushing,¹⁵ in a masterly article, referred to the influence of the nervous system on gastric function. Much that was valuable was resuscitated and further experimental work initiated.

That gastric changes can be caused by nervous lesions was first pointed out by Rokitsansky¹⁶ in 1846, and from then onwards isolated observations of organic brain lesions associated with gastric hæmorrhage and ulceration have been recorded. In 1875 Brown-Séquard¹⁷ showed that injury to the base of the brain produced gastric erosions. The association of subtentorial hæmorrhage and brain injury at birth with gastric hæmorrhage was also noted and commented upon. Cushing's interest in the subject was aroused by the death of three patients from perforated ulcer after operation for a brain tumour. Some time before this Beattie¹⁸ had shown that electrical stimulation of the nuclei in the region of the third ventricle leads to increased gastric peristalsis and hypersecretion; with continued stimulation gastric erosions could be produced. Severance of the vagi abolishes these effects, and identical effects are produced by direct stimulation of the vagus (McCrea, McSwiney, and Stopford,¹⁹ 1927; Beattie and Sheehan,²⁰ 1934).

Stimulation of the brain-stem in any part, from this centre in the region of the third ventricle down along the vagal tracts to the vagal nucleus, will produce the same motor and secretory changes in the stomach (Fig. 2). Cushing recalls that this centre is in the vicinity of Cannon's seat of the emotions, and it must of course be influenced by higher centres. Is this pathway unduly stimulated under certain circumstances? For example, do emotional upsets result in hypersecretion and hyperperistalsis in the man who complains of epigastric discomfort under tension, and who ultimately develops an ulcer? Can we show in our clinical experience any such relationship between the nervous system and the production of a peptic ulcer? Is the onset of symptoms, either initially or in recurrences, related to some primary disturbance first experienced in the nervous system? If the nervous system plays a primary part in initiating symptoms, we should meet with such a group of symptoms before the development of the ulcer, and there should be a high incidence of emotional upsets in recurrences.

FIG. 3.—Diagram of stomach showing location of ulcers in author's series.

Scope of Present Inquiry

In this lecture I shall try to show that clinical experience is in many respects in accord with the experimental and pathological findings I have outlined. Do not clinical "ulcers" form readily and heal readily, and is there not good evidence to confirm the essential action of an acid gastric juice? Moreover, is there not an "ulcer" type in which symptoms frequently follow an emotional upset, and in which relaxation brings relief not only to the mind but also to gastric function?

During the last five years I have personally observed and followed 377 patients showing a "chronic" ulcer. They have been seen frequently, and periodic

radiological examination has been carried out. The gastric secretion has also been repeatedly studied in a large number. The material is set out in Table II.:

TABLE II
Cases under Review

		Male.		Female.	
Gastric ulcers	145	75	70		
Duodenal ulcers	206	137	69		
Gastro and duodenal ulcers.. ..	11	6	5		
Post-operative ulcers..	15	14	1		
	377	232	145		

The proportion of females is somewhat high, and this is in all probability due to the preponderance of female patients at the Royal Free Hospital.

The Site of Ulceration

It is well established that the seat of the ordinary peptic ulcer is either in the first part of the duodenum or on the lesser curve of the stomach; it is seldom found in other parts of the stomach. In my series, as can be seen from Fig. 3, only 12 (3.4 per cent.) were on the posterior wall, and 13 (3.5 per cent.) in the prepyloric area. Of the 145 gastric ulcers 120 were on the lesser curve, and only 16 of these in the upper third; the middle third claiming 103. Only 1 was situated at the cardia. Those in the first part of the duodenum or on the lesser

curve of the stomach amounted to 94 per cent. This distribution is important—as Hurst²¹ has emphasised; and as Holmes and Hampton²² have recently pointed

FIG. 5.—A lesser-curve ulcer in a male aged 30. The second film shows the healing process a week later, with the disappearance of the crater at the end of a month in the third film. Ambulatory treatment.

FIG. 6.—A large lesser-curve ulcer in a woman of 42, who also showed an anæmia (Hb 40 per cent). Considerable diminution in size of crater is seen in 2½ weeks, and no trace of abnormality could be demonstrated in 6 weeks. Note the improvement in gastric tone observed in the final film (3 months).

out—in the differentiation between ulcer and cancer. Carcinoma of the stomach is usually a pyloric lesion, whereas only about 3 per cent. of benign ulcers are in the prepyloric area. It is well, therefore, to treat these prepyloric lesions as potential cancer, and, as Hurst maintains, operation on them is the wiser plan.

Rapidity of Formation of Ulcer

While histories of dyspepsia for ten years or more are common, some patients give only a history of a few weeks but nevertheless show a well-defined crater. The size of the ulcer crater is certainly not proportionate to the length of dyspepsia. Occasionally one has a chance of gauging the time of appearance of an ulcer, as in one of my patients, a man of 64, who had had dyspepsia for four weeks. A barium meal examination disclosed no ulcer crater; nor was anything abnormal seen at a second examination at the fifth week. At the eighth week, however, a large crater was plainly demonstrable (Fig. 4). In another case a large crater on the lesser curve was found in a man of 68 with only three weeks' dyspepsia.

Table III. shows the duration of symptoms in my series.

It will be seen that as many as 76 (23 per cent.) gave histories of less than three months' duration, and it is unlikely that in all these persons the ulcer

FIG. 7.—Ulcer of lesser curve in a woman aged 50, with complete disappearance in five weeks. Ambulatory treatment.

FIG. 8.—A large lesser-curve ulcer in a woman aged 49, showing restitution to normal in 13 weeks. Ambulatory treatment.

crater preceded the symptoms. Remissions extend over a number of years, and the patient may enjoy freedom even without treatment for a considerable period. Unfortunately little is known of the radio-

TABLE III
Duration of Symptoms

—	Under 3 mths.	12 mths.	2 yrs.	4 yrs.	6 yrs.	6 yrs. +
Gastric ulcer	44	24	20	11	19	23
Duodenal ..	32	38	26	31	24	55
Total ..	76	62	46	42	43	78

logical state in spontaneous remissions, but it is possible that a large number of ulcers do heal only to break down again in a recurrence.

Much interest is being shown towards cases in which the patient has the symptoms of peptic ulcer, relieved by taking alkalis, yet no ulcer can be found. During the past five years I have collected 8 cases of this kind, in which barium meal examination was repeatedly negative over 2-4 years, but in which an ulcer crater eventually developed. While it would be true to say that these persons had suffered dyspepsia for a long period, the development of an actual ulcer was much more recent. For example, one of them, a woman of 33, had suffered periodic dyspepsia for ten years, and barium meals in 1931, 1932, and 1933 had disclosed no gastric or duodenal lesion; yet in 1935 a lesser curve ulcer became apparent.

The length of symptoms is therefore not necessarily an index of the chronicity of an ulcer. It may be that the actual ulcer crater develops in man more rapidly than we have been led to believe, and that it is not correct to regard the patient who has suffered from dyspepsia for ten years as having had an ulcer of the same duration. Is it not possible that the ulcer comes and goes, heals and breaks down again, instead of being a "chronic" indolent lesion persisting for years?

The Healing of the Ulcer Crater

From time to time much criticism has been levelled against the radiological interpretation of healing of the ulcer crater. It has been suggested that the size of the crater as seen radiographically is largely the result of surrounding oedema, and that medical measures merely dispel the swelling. There is some truth in this criticism; but on the other hand, a lesser curve ulcer can be fairly sharply outlined,

and its diminution in size followed at frequent intervals without any difficulty until it disappears. Nicholas and Moncrieff showed the disappearance of the crater under treatment.²³ Symptoms are dispelled within a few days of adequate treatment, but I have been equally impressed with the rapidity with which repair proceeds and the crater diminishes in size. Considerable improvement is seen in 10-14 days, and in some favourable cases all trace of abnormality has disappeared in 28 days.

Of my lesser-curve ulcer patients 95 were followed sufficiently regularly to provide some information as to the time of ulcer disappearance (Table IV).

TABLE IV

Time of Disappearance of Ulcer Crater (Lesser Curve)

Weeks	3	4	6	8	12	16	24
	10	..	16	..	10	..	23
					23	..	6
							7

It can be seen that 82 were clear in three months and 59 in two months, and these figures gain significance from the fact that only a small minority—

FIG. 9.—Ulcer of lesser curve, with an hour-glass stomach, in a woman of 55. Disappearance of ulcer crater in two months but persistence of the hour-glass deformity. Ambulatory treatment

18—received hospital treatment, the bulk being treated while still at their work. Individual examples of this rapid healing can be seen in Figs. 5-8. In addition to the disappearance of the crater, the gastric tone improves and the shape of the stomach becomes more normal.

A mechanical abnormality, in the form of an hour-glass stomach, is not a bar to the temporary healing of the crater, although such a mechanical defect should be corrected by surgical means without delay, even if it does not give rise to symptoms, for the ground is prepared for further ulceration and recurrences are likely (Fig. 9).

I am unable to demonstrate such significant changes in duodenal ulcer, for some deformity of the cap usually persists in all but the very small craters. There is, however, an obvious improvement in the films which initially show gastric delay and retention. An improvement in tone is observed, and this improvement may persist for years; the delay in emptying is corrected and the signs of early "pyloric stenosis" disappear. Indeed, the response to treatment is often astonishing as is illustrated by the following case:—

A woman of 68 showed the radiographic appearances of early pyloric stenosis in 1932, in that there was gastric delay, a dilated stomach, and a duodenal deformity. Her weight was 8 st. I had intended, after a preliminary course of lavage and medical treatment, to advise a gastro-enterostomy, but her improvement was maintained, and it has so far been unnecessary to consider operation. The radiogram taken in 1935, three years later, shows a better tone, and the stomach now empties in normal time. Her weight has also increased from 8 st. to 11 st. 2 lb.

It behoves us, therefore, to distinguish between actual obstruction and retention; and although radiography is a sure guide in advanced cases, a preliminary course of medical treatment is necessary to distinguish cases in which there is more gastric retention than actual obstruction from those in which surgery is essential for relief. This has been well brought out by Emery and Monroe.²⁴

The only absolute proof of complete healing is that obtained by actual inspection of the stomach at operation, and this is rarely possible. The following details are instructive.

(A) 12.iv.33 (B) 2.vi.33 (C) 8.i.34

FIG. 10.—An ulcer crater on the lesser curve in a man aged 45. The first diagram does not indicate the real size of the crater, for its upper part was occupied by a large gas bubble. The second film shows a lessening in size of the crater in the sixth week. An acute appendicitis developed 8 weeks later, but no gastric lesion could be traced by the surgeon. The third film shows a return of the crater in 10 months' time. Ambulatory treatment.

A man of 48 gave a history of six weeks' dyspepsia. On one occasion five years previously he had suffered from indigestion, but he had remained well in the interval. An ulcer crater was demonstrated on the lesser curve of the stomach (Fig. 10 A). A second examination after six weeks showed much diminution in the size of the ulcer crater (Fig. 10 B), but no further proof of his response was available until eight weeks later when he was suddenly seized with severe abdominal pain and admitted to another hospital as an abdominal emergency. A diagnosis of a perforated ulcer was most probable, but to the surgeon's surprise no lesion could be found in the stomach, and the cause of the emergency proved to be an acutely inflamed appendix. Such evidence of healing is seldom obtainable. It must be added that he lapsed from treatment and returned to me in ten months with a recurrence of his symptoms and the ulcer crater (Fig. 10 C).

Anxiety and tension seem to delay the healing process, and complete rest in bed is occasionally required before symptoms can be dispelled and before any impression can be made on the size of the crater. If there is mental unrest the use of sedatives to produce relaxation is desirable.

One of my female patients showed considerable tension and nervousness, and the healing of the large crater was not realised until treatment had lasted ten months. The history was five weeks, but much weight had been lost and the general condition was very poor. No demonstrable change in the size of the crater followed upon a month's treatment, but some diminution was apparent in three months and again five months, although ten

9.iii.34 6.iv.34 13.vi.34 23.i.35 9.viii.35

FIG. 11.—A huge crater arising from the lesser curve in a woman aged 62, who showed considerable emaciation (5 st. 9 lb.), but gave a history of only 5 weeks. The second film (taken prone) shows no improvement after a month's treatment, but at the end of 3 months the crater is considerably smaller. The last film, 18 months from the commencement of treatment, shows a normal state. Gain in weight from 5 st. 9 lb. to 8 st. 6 lb.

months elapsed before the crater actually disappeared (Fig. 11). After two years there is no recurrence; the patient is symptom-free and her weight has increased from 5 st. 9 lb. to 8 st. 6 lb.

In spite of the utmost attention the ulcer crater occasionally persists, and I have records of six lesser-curve lesions which did not respond to treatment. In one of these cases two admissions to a medical ward failed to dispel the crater and surgery was required. The details of this group are given in Table V.

TABLE V
Persistence of Ulcer Crater

Case and sex.	Age.	Duration of symptoms.	Remarks.
1. M.	50	15 years.	Active ulcer at operation.
2. F.	34	1 year.	Fatal hæmatemesis, sixth month.
3. F.	34	3 years.	Active ulcer; mid-gastric fibrosis.
4. F.	40	2 "	Sixth month, active ulcer.
5. F.	54	1 month.	Large crater sixth month; brain tumour.
6. F.	56	2 years.	Active ulcer at operation.

Position of Ulcer.—Lesser curve in each case.

In the second case hæmorrhage occurred in the sixth month and proved fatal. If a crater shows no sign of healing within three months surgical interference should be advised, and my failure to act on this principle undoubtedly resulted in this tragedy. No apparent explanation is available for the lack of response in the other patients, except No. 5.

The patient was a female, aged 54, who had had hæmatemesis after some mild indigestion. After six weeks a barium meal showed a lesser-curve ulcer, which was still present in twelve weeks' time. This was regarded as unusual, and exhortation for more thorough treatment was made. Further radiography in the sixth month showed a crater larger than on the two previous occasions. At this time the patient complained for the first time of giddiness and weakness in the right upper limb. The weakness of the arm progressed and the signs of a tumour compressing the upper cervical cord advanced rapidly. An attempt to locate and remove this tumour was unsuccessful, and a tumour arising from the bulb was seen producing a pressure cone compressing the bulb and upper cervical cord. The nature of the tumour is uncertain, for it was degenerate when an autopsy was performed. The stomach was the seat of multiple erosions as well as a large ulcer crater which first caused symptoms. While I cannot definitely state that the two lesions had any bearing upon one another, it is possible that the tumour did irritate the vagal nuclei in the medulla and that this repeated stimulation resulted in gastric erosions and hæmorrhage and a chronic ulcer which resisted treatment.

With the exception of these six cases we find undoubted radiological evidence of healing in more than 100 lesser-curve ulcers. This response to treatment occurred while the majority of the patients remained at their work, a fact which further supports the statement that ulcers heal readily. On the other hand, a crater which persists in spite of medical attention should certainly be looked upon with suspicion, and if at the end of three months it is still seen with X rays, operation should be considered.

So far, then, we have found nothing at variance with the experimental observations, and we can safely conclude that the vast majority of ulcers readily heal on medical measures.

(To be concluded)

FURTHER OBSERVATIONS ON THE RÔLE OF THE TOXIN IN STAPHYLOCOCCAL INFECTION

By F. C. O. VALENTINE, M.B. Camb., M.R.C.P. Lond.
ASSISTANT DIRECTOR OF THE HALE CLINICAL LABORATORIES
LONDON HOSPITAL

In a previous paper¹ on staphylococcal toxin evidence was brought forward showing that certain strains of cocci are capable of producing a true leucocidin which destroys the phagocytes of human and rabbit blood and which is distinct from the hæmolyzing and necrosing factor also present in the toxin.

The Medical Research Council recently promoted an inquiry, to which a contribution was made at the London Hospital, into the value of toxoid injections in the treatment of staphylococcal infection. This supplied an excellent opportunity for continuing the work on leucocidin and its significance. The present paper describes methods of making toxin and of estimating the leucocidin in toxin and the antileucocidin in serum, and provides fresh evidence indicating that α -hæmolysin and leucocidin are distinct entities. Finally the methods described are employed in connexion with human material in an attempt to determine the rôles of the two toxins in human disease, attention being chiefly concentrated on the leucocidin.

The Investigation

PREPARATION OF TOXIN

The medium employed has been soft meat—infusion agar at pH 7.6, containing 0.5 per cent. agar.

Medicine bottles make convenient vessels for the purpose; if they are filled about one-quarter full no medium escapes when they are laid flat on their sides, in which position the agar is allowed to set. They are then inoculated by a Pasteur pipette from a fresh broth culture, excess of fluid after spreading being removed as much as possible. The bottles, still horizontal, are placed

in a desiccator from which the air is exhausted on the water-pump until the manometer reads about 600 mm. when it is replaced by a mixture containing 80 per cent. O₂ and 20 per cent. CO₂. The vessel is then incubated for 24 hours only.

Next morning the bottles are removed and are placed upright which causes the agar to fall to the bottom. A little shaking breaks it up so that it can be poured into filter paper in a Buchner funnel where it is sucked dry on the water-pump. At this point it is advisable to test the reaction of the filtrate and if it is inclined to be alkaline acidify until the colour with phenolsulphonephthalein is orange (about pH 7). The filtrate is then passed through a Berkefeld candle to sterilise it; a Seitz filter may be used but seldom removes all the cocci at the first filtration and a second filtration removes much of the leucocidin.

It has seemed to be important to use a medium with enough agar to present a reasonably firm surface for inoculation, but for the purpose of filtration through paper the softer the agar is the better. The optimum strength is about 0.5 per cent. agar and shaking should be avoided until after incubation.

The method of preparation used seems to permit the production of abundant leucocidin and of a fair but certainly not maximal hæmolysis. In the course of the present work it has been found that leucocidin is less stable than α -hæmolysin, the titre diminishing fairly rapidly, especially in the presence of free oxygen. But for the purpose of serum-toxin titrations it has been found desirable to use a comparatively large test dose of toxin, and in these circumstances toxins can be used for two or three months if kept sealed in a refrigerator.

Recently, however, I have found that filtration, whether through Seitz or candle filter, removes a variable quantity of the toxin. This effect, as might be expected, is greatest when the original concentration of toxin is low, and may be almost negligible with a strong toxin. It may therefore happen that a preparation which was originally strongly hæmolytic but feebly leucocidal may be found after filtration to be still strongly hæmolytic but without any demonstrable leucocidin.

The staphylococcal strains which have been used for the production of toxin were originally maintained in the refrigerator in blood broth, but it was found that this method was unsatisfactory for preserving their toxigenicity. Latterly Worth's medium has been used with better results, but there is still evidence of a gradual diminution in toxigenic power particularly affecting leucocidin production.

TESTING SERUM AND TOXIN

1. *Hæmolysin*.—It has now been established by Glenny and Stevens² following the work of Bigger, Boland, and O'Meara,³ and Bigger,⁴ that staphylococcal toxin may contain two separate hæmolytic factors, α and β . Since there is no evidence indicating that the β -toxin is of importance in human infection, the α -toxin only has been taken into account in the present work; and it has been assumed that the ability of the α -toxin to lyse rabbit red cells, to cause necrosis of living tissue, and to kill rabbits on intravenous injection is due to the presence of one factor which may be designated and estimated as α -hæmolysin.

The anti-hæmolysin content of all human and other sera tested in the course of the present work was estimated against the standard toxin B.8750 supplied by the Wellcome Laboratories, and this in its turn was always controlled against their K-serum B.8760, which is stated to contain per c.cm. 150 international units of anti-hæmolysin. In this paper all figures for anti-hæmolysin are given in terms of the international unit.

The hæmolytic activity of toxins has been estimated against K-serum and will be expressed as the L.H. dose—i.e., the smallest volume of toxin still hæmolytic for 1 per cent. rabbit cells after mixing with 1 unit of antitoxin.

2. *Leucocidin*.—No unit of antileucocidin has as yet been established nor is the existence of a specific leucocidin universally recognised. It is necessary therefore to describe how leucocidin and antileucocidin may be demonstrated and estimated.

For this purpose the washed cells of human blood have been used as a routine, the blood being first taken into 2 per cent. citrate in normal saline. It is advisable to reserve a few cubic centimetres of blood in a dry tube so that a supply of homologous serum is available.

For the test small tubes of 8 or 9 mm. internal diameter have been used. In serum-toxin titrations each tube receives 0.1 c.cm. toxin dilution and 0.1 c.cm. serum dilution, one of which is standard. These are mixed and allowed to stand for 5–15 minutes at room temperature. 0.1 c.cm. of washed concentrated cells is added and the tube again shaken and incubated for one hour. 0.1 c.cm. of homologous serum may then be added; this improves the quality of films made from the mixture and also prevents any further action of the toxin. The tubes are then re-shaken and a film is spread from each by platinum-loop, a method which has been found to cause less damage to the cells than spreading with another slide. Films are finally stained with Leishman. For estimating the titre of leucocidin in the absence of antibody the latter is replaced by saline.

After a little experience of the method the films are best examined under the $\frac{3}{8}$ in. objective with a $\times 10$ or $\times 14$ eyepiece. The "bird's-eye" view thus obtained is invaluable for comparing different films while individual cells can be checked with the high power. The titre of a toxin is indicated by the highest dilution from which the Leishman film shows no recognisable polymorphonuclear neutrophils. The titre of a serum is given by the highest dilution in which recognisable neutrophils persist. The latter titration is therefore open to the objection that for the demonstration of the end-point a sufficient excess of toxin must remain to destroy all the phagocytes which are present. But it has been found that even in "normal" human serum the amount of antileucocidin is sufficiently large and variable to permit the use of a very large test dose of toxin, roughly 16 times the amount of fresh toxin needed to destroy the same number of leucocytes in the absence of all antitoxin. In these circumstances titrations with 100 per cent. differences are sufficiently accurate and give a clear end-point.

For the titration of immune horse-serum greater accuracy is desirable and can be obtained. It is then important that the toxin should be quite fresh so that a small excess may be demonstrable. It is also practicable to double the volumes of serum and toxin dilutions in each tube (to 0.2 c.cm. of each) while leaving the volume of cells at 0.1 c.cm. In this way successful titrations with 25 per cent. differences have been made.

It happened that for the first tests made on human serum in the course of the present work, a batch of toxin was used which was neutralised by its own volume of K-serum diluted 1 in 100 but not by 1 in 200. It was also found that the smallest amount of antileucocidin commonly present in normal human serum was equivalent to K-serum 1 in 100. This amount is therefore suggested as a useful antileucocidin unit, although in this paper all figures are given in terms of K-serum.

Toxins are standardised by finding the lowest dilution which is inactive after mixing with an equal volume of K-serum diluted 1 in 100. Since 100 per cent. differences have been employed in all titrations throughout the present work, it has been sufficient to find the highest dilution of a toxin which is still active after mixing with an equal volume of K-serum diluted 1 in 200. The toxin could then

be used in this dilution for the titration of unknown serum, being always controlled against K-serum in the critical dilutions of 1 in 100 and 1 in 200. For more accurate estimations smaller differences are necessary and, as has been indicated above, can be used.

The antileucocidin here discussed appears as a true antibody to be found in the serum of horses and rabbits following the injection of leucocidal toxin. It also occurs in the serum of patients in the course of staphylococcal infection. Tests which have been made on horse serum indicate that the antileucocidin content may be concentrated in the pseudoglobulin fraction with the antihæmolysin.

THE LACK OF RELATIONSHIP BETWEEN α -HÆMOLYSIN AND LEUCOCIDIN AND BETWEEN THEIR ANTIBODIES

The experiment shown in Table I. compares the activity of two filtrates and shows that the ability of a staphylococcal strain to produce α -hæmolysin is unrelated to its ability to produce leucocidin. One

 L + = complete destruction of human neutrophils.

of these toxins was produced by the well-known strain Wood 46, and the other, toxin C, by a coccus isolated from a large carbuncle.

If filtrate Wood 46 contains 16 times the amount of hæmolysin present in filtrate C, and the latter contains at least 250 times the leucocidin present in Wood 46, it would seem that α -hæmolysin and leucocidin must be distinct.

That antihæmolysin and antileucocidin also vary independently of each other is illustrated by the example of a horse immunised at the Lister Institute by Dr. McClean. This horse had previously been immunised against α -hæmolysin and its serum, at the beginning of the experiment here described, contained approximately 150 units antihæmolysin and 0.5 K antileucocidin. After immunisation with a toxin prepared in this laboratory, containing a moderate α -hæmolysin and fairly strong leucocidin, the serum titres were approximately 100 units antihæmolysin and 4 K antileucocidin, the former having fallen slightly while the latter increased eightfold.

EFFECT OF TOXIN ON THE RABBIT LEUCOCYTE

If rabbit's blood is substituted for human in the leucocidin titration of a filtrate which contains a feeble α -hæmolysin but powerful leucocidin, the result will be comparable to that obtained by the use of human cells; the phagocytes will be destroyed by dilutions of toxin which leave the red cell untouched. The rabbit neutrophil, in fact, appears to be somewhat more susceptible to leucocidin than is the human cell.

But if a filtrate strong in α -hæmolysin but almost wholly lacking in leucocidin, such as is produced by

strain Wood 46, is tested against both human and rabbit blood, the results of the two titrations will be strikingly different. With the human cells in very low dilutions of the toxin there may or may not be some degree of hæmolysis or of damage to the leucocytes or both. This destructive effect has usually disappeared in dilutions as low as 1 in 4, and it is impossible to decide whether it is due to a slight susceptibility of the leucocytes to α -hæmolysin, to a trace of true leucocidin, or to other factors, possibly non-specific, present in undiluted filtrates. With rabbit blood hæmolysis, of course, occurs, but this is accompanied quantitatively by destruction of the leucocytes. There seems to be no reason to attribute this phenomenon merely to the accompanying hæmolysis, since in the case of human cells hæmolysis is not necessarily accompanied by any destruction of the leucocytes. It would rather seem that the rabbit leucocyte, like the rabbit red cell, is destroyed by α -hæmolysin against which human cells, both red and white, are relatively, if not absolutely, resistant.

The appearance of a rabbit leucocyte destroyed by α -hæmolysin is different, as a rule, from that of a human or rabbit cell destroyed by true leucocidin. In the latter case the cell, in an effective concentration of leucocidin, takes up a spherical form, the granules being arranged mainly at the circumference; in the presence of an excess of toxin the cell bursts and the granules are set free, and this appears to occur invariably in the making of a dried film once the cell has become spherical. But the rabbit neutrophil, killed by α -hæmolysin, appears to be less fragile and commonly retains the granules, clustered in one part of the cell, even in a dried film.

It seems possible that this difference in the morphology of the rabbit neutrophil, according as it is killed by α -hæmolysin or true leucocidin, may account for the existing uncertainty as to staphylococcal leucocidin, whether it is to be regarded as distinct from, or identical with, α -hæmolysin. It is possible that the different methods available for the demonstration of leucocidin may yield essentially different results. Thus the Neisser-Wechsberg test is based on the fact that a live leucocyte consumes oxygen and will therefore decolorise methylene-blue and that a dead cell will not. But there is no reason to assume that the granules or other substances released from a cell destroyed by true leucocidin should not still be capable, for a time, of absorbing oxygen. Further work is clearly necessary on the subject, but it may be pointed out that tests such as the Neisser-Wechsberg provide less direct evidence of the condition of cells than does the microscope and have the further disadvantage that they involve the use of animal and not human cells.

THE ANTITOXINS IN NORMAL HUMAN SERUM

Many human sera have now been tested for staphylococcal antitoxin by these methods. Amongst them 55 normal sera taken at random from those sent for the Wassermann test may be considered first.

It soon became obvious that the antileucocidin in human serum varies much more than the antihæmolysin. But the quantity of serum available was usually too small to allow a separate series of dilutions for each factor. As a routine therefore four tubes of comparatively widely spaced dilutions were used for each form of test, the first tube containing undiluted serum and each of the others three-eighths of the quantity in the preceding tube. Thus

serum, which completely neutralised the test dose of hæmolysin in the first tube only, contained 0.4 unit, in the second 1 unit, in the third 3 units, and in the fourth 8 units. The figures for the leucocidin tubes in terms of K-serum were 0.01 K, 0.027 K, 0.07 K, and 0.19 K.

Of 55 sera, 41 were found to contain 0.4 unit of antihæmolysin per c.cm., 13 contained 1 unit, and one 3 units, giving an average of 0.59 unit. This figure is probably a little lower than would have been obtained by a more accurate estimation, but it agrees sufficiently with the figures obtained by other workers.

In the antileucocidin estimations, 10 sera were equivalent to 0.01 K, 18 to 0.027 K, 19 to 0.07 K, and 8 to 0.19 K or more. The average figure thus obtained is 0.063 K, but if the 8 sera with titres of 0.19 K or more are omitted the average of the remaining 47 is 0.041 K. This latter figure is probably the more useful, for, as will be shown later, a serum titre of 0.19 K is usually indicative of existing or recent staphylococcal infection.

CULTURAL AND SEROLOGICAL INVESTIGATIONS CARRIED OUT ON PATIENTS

During the past eighteen months staphylococcal toxoid, as supplied by the Wellcome Laboratories, has been used at the London Hospital in the treatment of a series of cases of staphylococcal infection, the patients selected being for the most part examples of uncomplicated chronic furunculosis. A sample of serum was first obtained and then a series of injections was given at weekly intervals beginning usually with 0.25 c.cm. toxoid diluted 1 in 10 and working up to 0.5 c.cm. undiluted. After a total of at least 1 c.cm. of undiluted toxoid had been injected a second sample of serum was obtained.

In addition cultures were made when possible from lesions and latterly also from the anterior nares in order to confirm Dolman's observation⁵ that in chronic furunculosis virulent cocci are often present in the nose for long periods and may be carried from there to other parts of the body by the fingers. Eighteen cultures were made from the nares of patients not suffering from nasal lesions, and in all but 4 of these *Staphylococcus aureus* colonies grew out. From 7 of these strains filtered toxins were prepared and compared with toxins produced by cocci isolated from a lesion in the same patient. In all but 1 case the two toxins were sufficiently similar to suggest that the lesion-producing strain was being carried in the nose.

SERUM-ANTITOXINS IN CHRONIC STAPHYLOCOCCAL INFECTION

In a separate paper Dr. Burrows proposes to discuss the clinical effects observed in patients treated with toxoid injections. Only laboratory results therefore will be considered here.

Table II. shows the findings in 22 cases in which the full course of injections was given and in which the antihæmolysin and antileucocidin content of the serum was estimated both before and after treatment.

In this series the average figures for antihæmolysin before and after treatment are 1.8 units and 8.3 units respectively; but in only 4 cases was the average figure of 1.8 reached or surpassed before treatment, and of these 2 were cases of long-standing acne complicated by staphylococcal infection. If these two cases, Nos. 2 and 5, are omitted, the average titre before treatment is 1.14 units, a figure less than twice the normal 0.59.

The average antileucocidin titres before and after treatment are 0.22 K and 0.24 K. The insignificant

difference between these two figures is probably due to the fact that the toxoid used was prepared from filtrates of the type obtained from strain Wood 46, which gives very little leucocidin. But the average titre before treatment, 0.22 K, is important if the normal figure is accepted as 0.043 K. This five-fold rise was presumably due to the presence of

infection and its amount is significant. It suggests that in cases of chronic superficial staphylococcal infection the spontaneous serum-antitoxin response to leucocidin is better than that to hæmolysin.

This conclusion is supported by a consideration of the individual cases in the present series. In Cases 4, 5, 10, 11, 18, and 22, the antileucocidin titre rose between the two tests and this can be correlated with a persistence of the infection during the period of treatment, which was noted in all these cases. In Nos. 9 and 13 the antileucocidin titre fell slightly and no lesions occurred while the injections were being given. On the other hand, one case, No. 6, was still getting occasional boils at the end of the course but his antileucocidin titre, originally low, had fallen.

Nine other cases of primary superficial staphylococcal infection were treated with toxoid but through various accidents of non-attendance the second sample of serum at the end of treatment was not obtained. It is legitimate to add the figures obtained from the original sera of these patients in order to increase the number of cases on which the average titre in serum before treatment is based. The average figure for antihæmolysin in 29 cases thus becomes 1.2 units and for antileucocidin 0.25 K, Cases 2 and 5 in the original series being again omitted.

SERUM-ANTITOXINS IN CASES OF SEVERE INFECTION

The serum was also examined in 8 cases of more acute and serious staphylococcal infection. (Table III.)

This series is admittedly too small to be of much statistical value yet the cases fall into two groups, the first four being bled one week or less after the infection began and the second group after from two weeks to a month. The difference in the serum-antibodies

between the two groups is very striking. In the first group, the second and fourth cases were rapidly fatal, but the other two, both examples of face infection with much œdema, were clinically "settling" when the serum was taken. It seems, therefore, that with sound non-specific treatment clinical improvement may take place before the antibody titre is

TABLE III

Case.	Sex and age.	Anti-hæmolyisin units.	Anti-leucocidin in terms of K.	Remarks.
1	F 53	0.4	0.02	Lip infection with œdema. Bled after 1 week.
2	M 11	0.4	0.04	Ileum infection fatal. Bled within 1 week.

appreciably raised. Three cases in the second group show the typical rise of anti-hæmolyisin titre which occurs after deep-seated staphylococcal infection, but in addition there is an even greater proportionate rise in antileucocidin. The figure of 2.5 K, twice obtained, appears both remarkable and significant. The other case, No. 6, one of severe hand infection, showed a great rise in antileucocidin titre but none in anti-hæmolyisin. There is no reason to doubt the accuracy of this titration, but it was unfortunately impossible to confirm it on a second sample of serum, since the patient when on the point of recovery died of an intercurrent infection.

TOXINS

In a previous paper¹ evidence was brought forward indicating that it is usual to find that strains of staphylococci isolated from serious lesions are capable of producing leucocidin in considerable amount, whereas it is generally agreed that no such correlation can be made between virulence against human beings and the ability to produce α -hæmolyisin. In the course of the present work toxins were prepared from 25 strains isolated from furunculosis cases, from 6 strains derived from cases of serious infection, and from 5 strains associated with sycosis barbe. It was found that hæmolyisin production bore no relationship to the severity of the lesion from which a strain was isolated; but that all the strains from the cases of serious infection and all but 4 of the 25 strains from boils produced leucocidin in considerable amount, while no strain derived from sycosis produced any demonstrable leucocidin at all. There can be no doubt that these results have been modified to some extent by the recent observation that filtration of a toxin removes or greatly diminishes a toxic factor which is only present in small amount and thereby exaggerates differences of toxigenicity of different strains. None the less it seems probable that strains capable of invasion of tissue, such as occurs in the true boil and in more serious lesions, will usually be found capable of producing leucocidin in considerable amount, whereas in sycosis invasion of tissue is slight and the cocci present appear to be feeble leucocidin producers.

Discussion

It is now generally admitted that staphylococcal toxin has several different properties. The majority

of workers hold that its α -hæmolytic, necrosing, and lethal activities are probably due to the same substance. The β -hæmolyisin and the coagulase have been shown to be separate bodies.

As regards the leucocidin, some workers hold it to be a distinct entity, whereas others believe that the α -hæmolyisin destroys leucocytes as well as red cells, and that the staphylococcus does not produce a true specific leucocidin. The present work suggests that this divergence of opinion has arisen from the double action of α -hæmolyisin on rabbit leucocytes and red cells, whereas many strains of staphylococcus produce also a true leucocidin capable of destroying all phagocytic leucocytes both in human and rabbit blood, but without effect on red cells and lymphocytes. This leucocidin is capable of acting as an antigen and gives rise to a specific antibody either on injection or following its liberation into the tissues by the cocci in the course of infection.

RÔLE OF THE DIFFERENT TOXINS IN STAPHYLOCOCCAL INFECTION

It would be very unwise to attribute all the manifestations of staphylococcal infection to toxins produced by the cocci. For example, the remarkable ability of these organisms to survive on the skin and in the nares is probably a most important factor in the maintenance of chronic furunculosis. Cellular constituents such as the carbohydrate substance recently described by Julianelle⁶ may be of the utmost importance, for example in the production of hypersensitivity. These two factors together may conceivably lie at the root of the difficult problem of sycosis.

But the importance of the toxins, particularly when the infection has penetrated beneath the surface of the skin, is surely unquestionable. It is difficult not to correlate the massive local necrosis produced by the injection of α -hæmolyisin into a rabbit's skin with the local necrosis which characterises the ordinary furuncle, the commonest of staphylococcal lesions. The comparatively poor development of circulating anti-hæmolyisin in many patients suffering from chronic furunculosis may be due to the fact that the toxin is fixed locally in the tissues and does not therefore stimulate a general immunity. In a deeply seated abscess the absorption of toxin appears to be easier since the circulating anti-hæmolyisin commonly rises considerably.

There is no need to labour the importance of a leucocidin capable of destroying the phagocytic cells of the blood. Its presence might be expected to facilitate the invasion of the tissue by the cocci and indirect evidence is here supplied in support of this view by the fact that strains of cocci, isolated from lesions in which real invasion of tissue has occurred in an otherwise healthy patient, nearly always produce leucocidin in considerable amount.

This finding has an important bearing on the methods used for the production of antitoxic serum which is used in cases of serious acute infection to prevent further invasion of tissue before the body has had time to produce its own antibodies. It is possible that in these cases the value of antitoxic serum depends more on the content of antileucocidin than of anti-hæmolyisin. It is not uncommon to isolate from a rapidly fatal case of staphylococcal septicæmia an organism which produces only a feeble hæmolyisin but a strong leucocidin. Even if it is true that toxæmia and death result directly from the accumulation of hæmolyisin and not of leucocidin, treatment should be directed towards

the prevention of further invasion as well as to the neutralisation of toxin already formed.

Through the kindness of Dr. Parish of the Wellcome Laboratories it has been possible to estimate the antileucocidin titre of 24 "normal" horses. Of these, 6 had a titre of 0.2 K but none of 0.4 K, and of the remainder the majority showed a titre of 0.05 K or less. Two horses have been immunised against a toxin rich in leucocidin, one by Dr. Parish and the other by Dr. McClean at the Lister Institute, and in each case a titre of 4 K was obtained, the titration, however, being only approximate, since 100 per cent. differences were used both for the estimation of the toxin employed and in the ultimate test of the serum. More recently a sample of concentrated serum kindly supplied by Drs. Dolman and Kitching from the Connaught Laboratories, Toronto, has yielded a titre of approximately 12 K. It would seem probable that a figure of at least 3 K should be readily obtained in the crude serum by the use of a suitable toxin. In comparison with these figures it would seem to be rare for a horse immunised with hæmolytic filtrates such as are yielded by strain Wood 46 to attain a titre of more than 1 K in the crude serum. In the near future it is intended at the Wellcome Laboratories to immunise a horse against a leucocidal toxin in which the hæmolysis has been neutralised, in the hope of establishing, if possible, a maximum antileucocidal figure for future reference.

The importance of leucocidin in chronic infection is probably much less than in the acute case, particularly with regard to treatment by toxoid. Whereas in chronic infection the patients often develop little circulating antihæmolysin, their antileucocidin response is usually considerable. It may be for this reason that serious staphylococcal infection seldom occurs in patients already suffering from chronic furunculosis. Even so, it would seem on general grounds to be desirable that the antigenic efficiency of toxoid should be maintained with reference to leucocidin as well as to α -hæmolysin.

Summary

1. A method is described for obtaining a staphylococcal toxin which, with a suitable strain, is reasonably rich both in α -hæmolysin and leucocidin. It is observed that filtration may remove all leucocidin from a toxin originally feeble in this respect.

2. Methods are given for the estimation of leucocidin in toxin and of antileucocidin in serum. A convenient unit of antileucocidin is suggested in terms of the standard K serum, B 8760, issued by the Wellcome Laboratories.

3. A description is given of the susceptibility of the rabbit leucocyte to α -hæmolysin, towards which the human cell is relatively if not absolutely immune.

4. Confirmation is supplied of Dolman's finding that in chronic furunculosis virulent staphylococci are commonly carried in the anterior nares.

5. Evidence is produced indicating that in chronic superficial staphylococcal infection the antileucocidin of the serum commonly shows a significant increase, whereas the antihæmolysin often does not; also that in deep-seated infection the rise in the anti-hæmolytic titre of the serum is accompanied by a relatively greater increase in antileucocidin.

6. A comparison of the toxigenic capacity of a number of different strains of cocci suggests that strains which have succeeded in invading human tissue will commonly be found capable of producing leucocidin in considerable amount.

The importance of the concentration of antileucocidin in antitoxic serum is discussed.

My thanks are due to Dr. P. N. Panton for his unflinching advice and criticism; to Dr. H. J. Parish and Dr. Joyce Wright of the Wellcome Laboratories for their criticism and for the supply of standard serum and hæmolytic toxin; also for their collaboration and that of Dr. McClean, of the Lister Institute in the immunisation of horses; and finally to Dr. Burrows and other members of the medical staff of the London Hospital for access to the human material on which the work is based.

OPERATION FOR FEMORAL HERNIA BY A MIDLINE EXTRAPERITONEAL APPROACH

WITH A PRELIMINARY NOTE ON THE USE OF THIS
ROUTE FOR REDUCIBLE INGUINAL HERNIA

BY ARNOLD K. HENRY, M.B. Dub., F.R.C.S. Irel.

DIRECTOR OF THE SURGICAL UNIT, KASR-EL-AINI HOSPITAL;
PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY
OF CAIRO

THE admission of a case of femoral hernia to my surgical unit is so rare as to be something of an event. During the past year (July, 1934-June, 1935) we have operated on 2 such cases as against 205 of inguinal hernia, a high incidence considering the fact that in the nine previous years only 3 other patients with femoral hernia were admitted to my beds. I venture therefore to describe an operation that I have performed once only, in the hope that others with better opportunity will test the method and assess its value.

At Kasr-el-Aini Hospital the frequency of bilateral lesions of the urinary tract has made us familiar with the midline extraperitoneal approach to the pelvic ureter, and using this route recently I was struck by the admirable exposure it gave of the whole region of the femoral ring. In a thin patient, as soon as my hand had displaced the peritoneal sac from beside the bladder, the view obtained of the four relevant structures—Gimbernat's ligament, the hinder edge of Poupart's, the fascia covering the pectineus, the external iliac vein—was like that in a specimen prepared for demonstration. This clear view showed me that the femoral ring could easily be closed by turning forward a flap of the dense fascia covering the pectineus muscle, and sewing it to the hinder edge of Poupart's ligament.

We soon had the opportunity of putting these ideas into practice. A girl aged 14 (1935, No. 13647), who had developed phthisis five years previously, was admitted with bilateral femoral hernia of one year's duration. Both herniæ were reducible, and both projected through the saphenous opening without turning towards the anterior superior spine (Fig. 1).

THE OPERATION

Under gas-oxygen anæsthesia on July 10th, 1935, through a midline incision, I separated the recti at and below the navel, and stripped the unopened peritoneum from the sides of the bladder and from the pelvic wall. This at once gave a notable view

of both hernial sacs, which stood out from the peritoneum like horns from a snail, and passed into the femoral rings (Fig. 2). After a very little blunt dissection the two sacs were delivered from the canals and brought within the abdominal wall; they were

FIG. 1.—The two femoral herniæ. (The incision extended from the pubic symphysis to the left side of the navel.)

then excised and their origins were closed. The right femoral ring admitted two fingers; the left was slightly smaller. Both were shut off in the following way, the entire operation "from skin to skin" lasting 32 minutes.

The fascial flap.—After retracting the external iliac vein outwards, I made two incisions through the fascia covering the steep slope of the pectineus muscle; the first, just in front of and parallel to Cooper's ligament, extending out for $1\frac{1}{2}$ inches from the free edge of Gimbernat's; the second running down and forwards at right angles to the outer end of the first. I then had a triangular flap of strong fascia—pedicled in front—which I turned forward and united by sutures to the hinder edge of Poupart's ligament. This closed the femoral ring (Figs. 3 and 4 A). The raw upper surface of the pectineus muscle remained bare, and to cover it I sutured the hinder edge of Poupart's ligament to Cooper's ligament. The second line of suture, however, was not essential and would seldom be so easily accomplished as in this case where Poupart's ligament was extremely lax.¹

I found that my assistant's hand formed the best retractor; his palm held the abdominal wall, while the tips of his fingers drew the external iliac vein aside as they slid outwards over the fascia covering the the pectineus.

The wound healed by first intention.

¹ The fascial flap can be raised in the opposite direction with its pedicle behind at Cooper's ligament (Fig. 4 B). This avoids leaving any raw surface of the pectineus exposed, though I doubt whether that has any real importance since the muscle covers the pubic ramus thinly at this proximal level and the danger of a recurrent hernia burrowing into its fibres is unlikely.

COMMENT

This method appears to have several advantages, apart from its obvious use in bilateral cases.

(1) When the recti have been separated, the sac is found by a gentle movement of the hand, without dissection. Its proximal part is at once delivered naked to the surgeon, and serves as a guide to the rest.

(2) The variably developed, unreliable, conjoined tendon plays no part in this operation. At best its arch is resilient and must be fastened under stress to Cooper's ligament. Should occasion, however, arise for its use, better access to the "tendon" is got by this route than by opening the inguinal canal.

(3) In contrast to the conjoined tendon the thick fascia covering the pectineus muscle can be relied on to furnish a strong flap that will join Poupart's ligament without tension and close the femoral ring.

(4) The immediate access to a wide surface of parietal peritoneum that is given by this approach makes it possible to close and invaginate the sac at its actual origin, abolishing the small diverticulum which may remain to favour recurrence when the neck of the sac is drawn down into a wound for ligature.

THE MIDLINE METHOD IN INGUINAL HERNIA

After the foregoing account was written I made (through the courtesy of Prof. A. F. Bernard Shaw) a preliminary trial of this extraperitoneal route in a cadaver with an inguinal hernia of moderate size. I found that the midline incision gave the same admirable exposure of the origin of the sac as in femoral hernia. The sac could be easily delivered, extraperitoneally, within the abdominal wall, and dealt with there by ligature and invagination. Access to the internal ring was good, and it was easy to repair it from within. Further experience has shown that this repair is always easy if the anæsthetist keeps the abdominal wall lax. Seen by this approach, the orifice presents an unusual and striking appearance. Its posteromedial lip is beautifully defined by a thickening of the transversalis fascia. The anterolateral boundary of the ring is formed by unthickened fascia covering the deep surface of the internal oblique muscle. By suturing these two

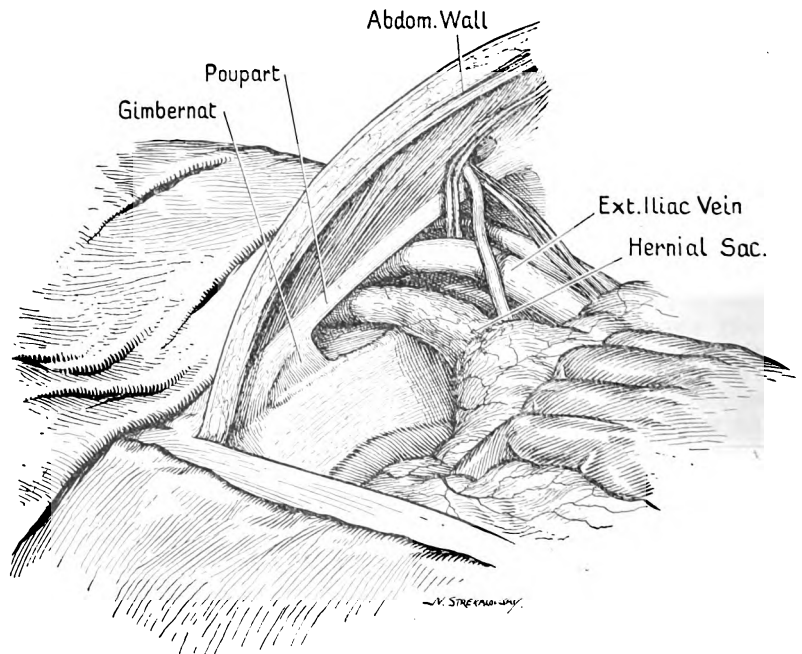

FIG. 2.—The right femoral sac seen from the left side, after separating the recti, when the hand has displaced the peritoneum.

boundaries of the ring together from above downwards the internal ring can be narrowed until it just transmits the cord.

I used the method first for inguinal hernia in the operating theatre in a case that was direct, bilateral,

a pedicled flap cut from the deep surface of the rectus muscle.

True and false necks.—Recently the extensive view of the parietal peritoneum obtained by the midline approach has revealed a condition that may have an

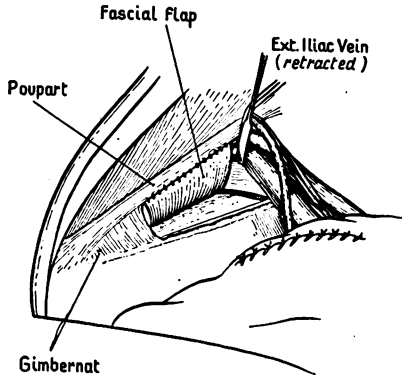

FIG. 3.—The flap cut from the pectineus fascia turned forward for suture to Poupart's ligament.

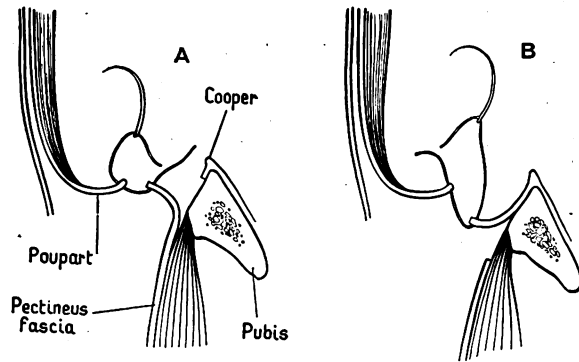

FIG. 4.—(A) The same flap as in Fig. 3, seen in longitudinal section. (B) Alternative method of cutting the fascial flap. The pedicle is at Cooper's ligament.

and reducible. After separation of the recti I was able at once to pick up each sac, and both were completely isolated and delivered within the abdominal wall in less than five minutes from the first incision. Narrowing of the ring too was rapidly accomplished by suture from within.

Indirect hernial sacs naturally are more closely attached by their outer surface to the spermatic vessels, but at this level, where the vas is already turning sharply away from the sac to enter the pelvis, their separation is simplified. It must however be remembered that when the peritoneum is raised from the abdominal wall, the vas deferens—though placed in extraperitoneal fat—will be raised too. The vas is lifted up on the tough fibrous cord of the obliterated hypogastric artery which underlies it and adheres to the peritoneum. Traction on the hernial sac also withdraws the vas, with the spermatic vessels, from the scrotum, so that sac, vessels, and vas lie loose and intricate within the belly wall.

It is notoriously hard to find planes of cleavage between slack structures, but here the difficulty is easily met by a second assistant, who grasps the scrotum beneath the towels and gently draws the spermatic cord towards the patient's feet. This simple precaution restores anatomical relations and greatly expedites the isolation of large hernial sacs.

The origin of the sac, which is closed by ligature or suture, can often be invaginated. To avoid injuring gut the "purse-string" should be passed while the sac is still open.

If reinforcement were required for the closure of the internal abdominal ring, it would be easy to cover the weak spot with

important bearing on recurrence after "radical cure." The tubular hernial sac often grows much wider just inside the internal ring and forms there a peritoneal pouch proximal to the so-called neck. The junction of this pouch with unevaginated parietal peritoneum is the true neck, origin, or inlet of the sac, and unless that inlet is shut recurrence is likely. It would however be difficult through the ordinary approach to avoid mistaking the wide proximal pouch for unevaginated peritoneum; the false, apparent neck would then be closed instead of the pertinent real one (see Fig. 5).

The more I use the midline route for operating on patients suffering from inguinal hernia only, the more I am struck by the fact that femoral rings often gape widely and admit a finger easily; yet there is no corresponding evagination; the peritoneum lies smoothly over them. I believe that the testimony of the wide field exposed by the extraperitoneal approach will confirm the theory that, apart from wounds or operation, a preformed congenital sac is an essential cause of most inguinal herniæ. Cure of the condition will only be radical, in the literal sense of that word, when, after excising the sac, we close its actual origin, and my impression is that in many cases repair of the canal must be superfluous, especially when the canal is valvular and the hernia indirect.

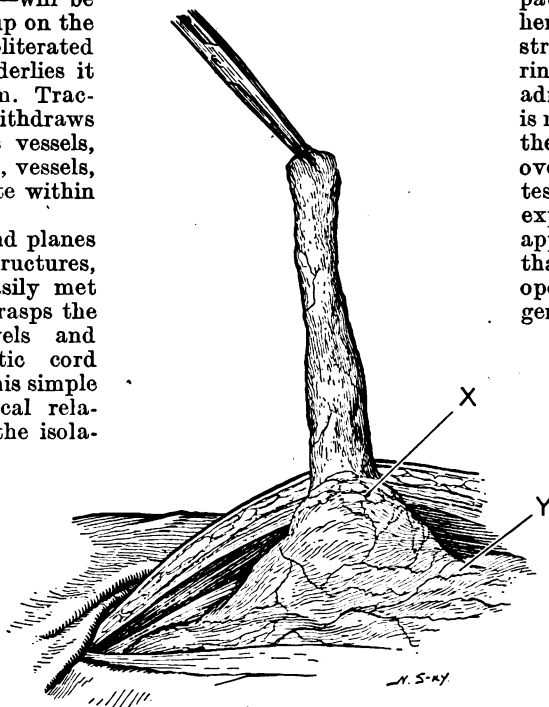

FIG. 5.—A wide pouch or diverticulum proximal to the false fat-encircled "neck" of the hernial sac (X)—a common finding (see text). The true inlet of the sac is where this pouch joins parietal peritoneum (Y). The junction is sometimes marked internally by a rim-like thickening.

My thanks are due to Dr. Mohamed Hasan el Zeneini, resident surgeon in the surgical unit, for much useful coöperation, and to Mr. N. Strelakovsky for his excellent drawings.

TEMPORARY PARALYSIS OF THE DIAPHRAGM IN THE TREATMENT OF PULMONARY TUBERCULOSIS

BY LAURENCE O'SHAUGHNESSY, M.D. Durh.,
F.R.C.S. Eng.

SURGEON TO THE BRITISH LEGION SANATORIUM, PRESTON HALL,
AND TO THE GROSVENOR SANATORIUM, ASHFORD; THORACIC
SURGEON TO THE LONDON COUNTY COUNCIL; AND

J. H. CRAWFORD, M.B. Leeds
ASSISTANT DIRECTOR, BRITISH LEGION SANATORIUM,
PRESTON HALL

It is almost five and twenty years since Stuert and Sauerbruch first induced artificial paralysis of the diaphragm as an accessory mode of treatment for pulmonary tuberculosis. Sauerbruch had practised phrenicotomy—or section of the stem of the phrenic nerve within the chest—at a much earlier period when carrying out the radical treatment of diaphragmatic hernia.

As phrenicotomy became more generally performed, it was apparent that paralysis of the diaphragm often failed to appear after the operation, and in 1922 Felix, after his masterly study of the anatomy of the nerve and its accessory branches, proposed and carried out the operation of phrenic evulsion, in which the nerve was exposed in the neck and its peripheral end was seized with forceps and evulsed from the chest. In this operation often a length of 10 cm. of the nerve was removed and a permanent paralysis of the hemidiaphragm naturally resulted.

In 1931 one of us (L. O'S.) published the results of a series of operations of the Felix type carried out in the Sudan; and up to that date phrenic evulsion appeared to satisfy his requirements except in the rarest cases. In that year, however, he had the opportunity of examining a patient subjected to a phrenic evulsion on the left side which had been followed by very distressing symptoms probably caused by a displacement of the stomach following an ascent of the diaphragm to the level of the third rib. Despite the rarity of this syndrome—Davison has recently reported 568 cases of phrenic evulsion without complication—this case was enough to bring the question of temporary paralysis into consideration, especially as other examples of gastric and cardiac distress following phrenic evulsion on the left side have been recorded by Rickers and by several others.

During the last three years it has been our usual policy in the treatment of pulmonary tuberculosis to induce a temporary rather than a permanent paralysis of the diaphragm. The only notable exception to this rule is in an operation undertaken for the obliteration of a persistent empyema cavity in the chest, when permanent paralysis is induced.

TECHNIQUE

The technique of operation is much the same as that described in a previous paper (L. O'S.).

The patient is given an injection of omnopon gr. 1/3 and scopolamine gr. 1/150 an hour before the operation. During the operation he lies on his back with a narrow sand-bag beneath the neck, fitting exactly between the occiput and the first dorsal vertebra, with his chin pointed up and away from the operation area. The line of incision, two fingers-breadth above the clavicle, is some 2 cm. in length, passing horizontally over the posterior border of the sternomastoid muscle in such a way that two-thirds of the incision is lateral to the muscle. An intra-

dermal weal is raised with a solution of $\frac{1}{2}$ per cent. Novocain in the line of the incision, and with due precautions 3 c.cm. of the solution is injected into the deeper underlying tissue.

After incision of the skin and platysma the posterior border of the sternomastoid muscle is exposed, defined by blunt dissection and retracted inwards. The posterior belly of the omohyoid is then exposed and retracted downwards and then the fascia covering the scalenus anticus comes into view. A subfascial injection of the anæsthetic solution is then carried out and, after a minute incision of the fascia, the surface of the muscle is defined by blunt dissection. The phrenic nerve is exposed running an oblique course towards the inner border of the muscle, and in the lower part of the wound it is seen disappearing beneath the transverse cervical vessels. The nerve is gently isolated, raised on a blunt hook, injected with novocain, and crushed with a strong pair of artery forceps. The wound is then closed by suture.

It will be observed that no attempt is made to identify and crush the accessory phrenic nerve, although this would seem in theory desirable. While recognising the importance of Felix's original work on the "neben-phrenicus," we can only state that the operation as described has produced paralysis in 43 out of the 44 cases, and in the single failure a more extensive dissection still failed to produce the desired result. In view of this we are disinclined to modify the simple technique outlined.

It must also be recognised that in phrenicoplasty,* as in phrenicotomy, there are certain local operative risks, and the operation should only be carried out by a surgeon sufficiently experienced to deal with the serious hæmorrhage which may result from the accidental wounding of an aberrant branch of the subclavian artery. It is well to remember that fatalities have been recorded from this complication. A second local complication, which may also have fatal results, is air embolism following a wound of the external or internal jugular vein. If part of a patient's lung is already rendered useless by disease, his reaction to the temporary blockage of part of the pulmonary circuit, which follows the admission of a small quantity of air into a systemic vein, is considerably more alarming than the trivial disturbance which is the only usual sequel to such an accident in a patient with healthy lungs.

RESULTS

In 43 out of the 44 cases which are the subject of this communication, phrenicoplasty produced a paralysis persisting for an average period of six months—in one case movement returned after five months and in another paralysis persisted for nine months—and it appears to give rather more consistent results than the alternative measures. In a recent account of the injection of alcohol into the nerve Morin records periods of paralysis ranging from five to fifteen months. In 4 of our cases a second operation was carried out when a further period of paralysis of the diaphragm seemed indicated, and in 1 of these paralysis failed to appear.

It is not our intention here to discuss the value of hemiparesis of the diaphragm in the treatment of phthisis. A recent review of the question by Morriston Davies renders this superfluous. There is also an analysis of 330 operations by Schwarzmann and Waltach and an account of 654 operations by Nehil and Alexander. The views expressed by one of us in an earlier paper as to the value of the operation have undergone little change. One of its most valuable uses is to supplement the régime of absolute rest imposed on the patient suffering from

* This term, derived from the Greek $\theta\lambda\alpha\omega$ (I crush, or bruise), is perhaps preferable to "phrenic crush."

FIG. 1.—Cavity system in right middle zone. Sputum contains tubercle bacilli.

FIG. 2.—Right leaf of diaphragm raised and paralysed. No T.B. in sputum.

FIG. 3.—Right leaf of diaphragm raised but moving. No T.B. in sputum. Patient at work.

an exudative lesion. The old controversy as to the value of paresis of the diaphragm in the case of lesion of the upper lobe seems to have been settled by the work of Weber on the röntgenkymography of the lung. As Kremer and von der Weth have also shown, diaphragmatic movement has a very definite effect on the upper lobe provided adhesions have formed in the interlobar sulcus, and the expert radiologist is now in a position to decide this point with certainty before operation is contemplated. Phrenicosthasty is never considered as an alternative to artificial pneumothorax. It is sometimes used to supplement an incomplete artificial pneumothorax, and it is often employed, we believe usefully, as a test operation before proceeding to more radical surgery; only rarely is it carried out as an independent measure. We have probably made too little use of the operation as a palliative measure for the irritative cough, dragging pain, and dyspepsia of the late case of phthisis.

CASE-HISTORY

Male, aged 27; two years' history of pulmonary tuberculosis commencing with a large hæmoptysis. On admission the right lung showed cavitation in both upper and middle lobes, with increased root shadows on the left side (Fig. 1). Artificial pneumothorax was tried without success, and a phrenicosthasty performed on the right side in January, 1934; the sputum was then markedly positive. Paralysis of the right leaf of the diaphragm was produced, paradoxical movement being observed on screening. Fig. 2 shows the radiographic appearance 2½ months after operation—the gradual disappearance of the cavities on the right side and the clearing of the contralateral side will be noted. The sputum was now negative and there was complete subsidence of all constitutional symptoms, the patient (a former bank clerk) now being up all day and doing 4½ hours' daily occupational therapy in the village settlement.

The initial duration of paralysis of the hemidiaphragm was 7 months, and at the end of this period a second phrenicosthasty was performed to maintain the paralysis. After this second operation, normal movement was observed to have returned at the end of 5 months. Fig. 3 shows the radiographic appearance at the end of this period; the diaphragm on the right side is still somewhat raised, while the cavitation is now completely resolved.

The sputum has remained consistently negative and the

patient has gained 22 lb. in weight. He has now returned to his normal employment.

CONCLUSION

Some have been led to advocate a crushing of the phrenic nerve rather than its evulsion because of the danger of producing some lesion within the chest during the latter procedure. We do not consider phrenic evulsion, discreetly and carefully performed, a dangerous operation but have adopted phrenicosthasty on quite other grounds. We have observed an increasing number of patients with bilateral phthisis for whom some form of bilateral collapse operation would offer a prospect, and the only prospect, of cure, but a paralysed diaphragm has ruled out such a possibility. In the young patient a paralysed hemidiaphragm does not produce signs of respiratory distress—indeed in a previous paper one of us has described patients who tolerated complete paralysis of the diaphragm with equanimity. But it has recently been suggested that in middle age paresis of the diaphragm may constitute a more serious handicap: Kochs found that phrenicotomy produced a greater reduction of vital capacity in middle-aged patients than in young patients. The possible detrimental effects of the paralysis on cardiovascular function in later life must also be borne in mind, and the recent experiments of Nissen and Wustmann on the effect of diaphragmatic movement on the caval blood flow are of interest in this connexion. We therefore believe that it will be of probable advantage for the patient described in the above case-history to have a healed tuberculous lesion and a moving diaphragm; for should his lesion again become active he is a suitable subject for any form of treatment which may be necessary, and if, on the other hand, his disease remains permanently arrested there is no chance of his having to pay for this benefit by an impairment of respiratory or cardiovascular function in his later life.

We wish to thank Dr. J. B. McDougall, medical director of Preston Hall, for permission to publish these cases, and Dr. A. Ross for his coöperation in their radiological investigation.

ACCIDENTAL TRANSMISSION OF MALARIA BY BLOOD TRANSFUSION

By W. L. THOMAS, F.R.C.S. Edin.

HON. SURGEON TO THE EAR, NOSE AND THROAT DEPARTMENT,
THE ROYAL HOSPITAL, WOLVERHAMPTON; AND

S. KEYS, M.R.C.S. Eng.

LATE ASSISTANT PATHOLOGIST AND BLOOD TRANSFUSION
OFFICER AT THE HOSPITAL

With a note by

S. C. DYKE, D.M. Oxon., F.R.C.P. Lond.

PATHOLOGIST TO THE HOSPITAL AND DIRECTOR OF THE
BLOOD TRANSFUSION SERVICE

THE following is believed to be the first instance of the accidental transmission of malaria in the course of blood transfusion to be reported in this country.

The patient was a man aged 26. He was first seen by one of us (W. L. T.) in May, 1935, with a malignant growth of the nasopharynx; for this he received radium treatment at the Royal Hospital. He was readmitted in August, 1935, with a diagnosis of septicaemia secondary to an infection of the middle ear; he was then seriously ill and emaciated, and had been running a remittent temperature of up to 103° F. for five days. Under treatment the temperature subsided in a fortnight, leaving the patient in a very weak condition. A week later, although there had been no further evidence of activity of the infection, he appeared to be losing ground. A blood count showed: haemoglobin, 38 per cent.; red cells, 2,040,000 per c.mm., and white cells, 7900.

In view of the anaemia it was decided to have recourse to blood transfusion, and a first transfusion was given on August 24th, 1935. As donor, a brother-in-law was used; blood of both donor and recipient belong to Group O (IV. Moss). Eighteen ounces of blood were withdrawn and administered. The transfusion was followed by considerable clinical improvement; on August 29th the blood showed Hb. 58 per cent., and red cells 4,220,000. A second transfusion was given on Sept. 9th. The same donor was again used and 10 oz. of blood was withdrawn and administered. Both transfusions were performed by S. K. On both occasions the blood was citrated; infusion was carried out by the three-way syringe; the infusion needle was introduced by vein puncture without incision.

On Sept. 12th, three days after the last transfusion, the patient developed a high intermittent fever with rigors. Examination of the blood on Sept. 17th showed: Hb., 38 per cent.; red cells, 2,440,000; white cells, 4400; no morphological abnormalities of red or white cells. Blood culture was negative.

The temperature and the rigors persisted and the clinical condition so impressed one of us (W. L. T.), who had had considerable experience of malaria in the Far East, with its general resemblance to tertian malarial infection, that a further examination of the blood was asked for. On Sept. 19th further films of blood were taken both about one hour before and actually during the

occurrence of a rigor, and in these the parasite of benign tertian malaria (*Plasmodium vivax*) was demonstrated without difficulty. On treatment with quinine binhydrochloride grs. 20 daily the rigors ceased and the temperature rapidly subsided. Quinine was continued in decreasing doses for two months. The patient was last seen on Jan. 14th, 1936; he had then had no relapse, his general health had much improved, and incidentally no sign of the nasopharyngeal growth could be found.

The patient had never been out of England and the possibility of his having contracted malaria in this country appeared remote in the extreme. Suspicion fell on the infused blood. Inquiry elicited the fact that the brother-in-law who had acted as donor was a regular soldier who had served in India from 1927 to November, 1933. The only illness from which he had suffered while in India was sandfly fever; while abroad he had never had any rigors. In June, 1934, after his return to this country, he had a short series of shivering attacks each lasting two or three days; his own doctor gave him some medicine, after which these attacks ceased and he had been perfectly well since. While in India he had not received quinine prophylactically.

Examination of the donor's blood showed no malarial parasites.

NOTE BY DR. DYKE

The transmission of malarial infection by the infusion, either intramuscularly or intravenously, of infected citrated blood is of course a commonplace of antisiphilitic treatment. The main interests in the above case attaches to the transmission of the infection by the blood of a person who had never knowingly suffered from malaria. The infection was evidently contracted in India; but there seems to be no doubt that the donor experienced no symptoms of the disease while there. He was questioned as to his attack of sandfly fever; this appears to have been mild but true to type and the fever was unaccompanied by rigors. Symptoms of malaria did not appear until he had been six months in this country, and were then mild and unrecognised as such.

In all about a score of cases of transmission of malaria in the course of blood transfusion from donors not known to be suffering from the disease are now on record. The first was reported by Woolsey¹ in 1919. The transfusion of blood from an apparently healthy donor to a patient suffering from pernicious anaemia was followed on the same night by symptoms of malaria. Immediate examination of the blood both of donor and recipient showed malarial parasites, and in spite of the absence of symptoms the donor was evidently suffering from heavy malarial infestation. This is the only recorded case in which examination of the blood of the donor showed malarial parasites; their presence in sufficient numbers in the blood to be demonstrable in ordinary films apparently accounts for the extremely short incubation period of the disease in the infused subject.

The whole subject of the transmission of malarial infection in the course of blood transfusion has lately been minutely examined by Ackermann and Pilatov² at the Leningrad Institute for Blood Transfusion. They have collected in all a total of 18 cases recorded up to the time they wrote. They are impressed with the danger of introducing malarial infection by the use of blood of donors who have ever dwelt in a district in which malarial infection is endemic. They experimented upon the effect of keeping blood with and without the addition of quinine.

For conservation of the blood they used a solution consisting of sodium citrate 5.0 g., sodium chloride 7.5 g., potassium chloride 0.2 g., and magnesium sulphate 0.04 g. to one litre of distilled water. To this was sometimes added quinine hydrochloride to the extent of from 0.2 to

1.0 g. to the litre. The blood was stored at 4° to 6° R. (5° to 8° C.). They found that, whether quinine had been added or not, after 12 hours' keeping the blood was always infective; after 24-72 hours it was sometimes infective, after 96 hours never. The addition of quinine seemed merely to decrease the severity of infection and possibly in some instances to render the blood non-infective.

Since the appearance of the work of Ackermann and Filatov, a further case has been reported by Harvier, le Brun, and Lafitte³ to the Société Médicale des Hôpitaux de Paris. The donor had been in Algiers for two years, ten years previous to giving the blood, and in Gaboon up to three years before; he had never knowingly suffered from malaria. He had regularly taken 0.25 g. quinine daily while abroad. In the discussion following the presentation of this case M. P. Émile-Weil said: "I have never had the annoyance of seeing malaria develop after a transfusion because I regard everyone who has been in the colonies or who has lived in a malarial country, even if they have not had fever, as being unrecognised malarial subjects (paludéen ignoré), and I refuse without having recourse to any biological tests to accept them as donors." M. Le Bourdellés, on the other hand, while admitting the existence of chronic cases only brought into evidence by the development of malaria after the infusion of their blood, expressed the opinion that these are "very rare occurrences and that a large number of malarial subjects after repatriation are completely cured from the clinical, hæmatological, and serological standpoints."

Various speakers in the course of this discussion made reference to "Henry's reaction" for the identification of malarial infection.

This reaction was described by Henry⁴ in 1928. Proceeding from the fact that malarial infestation leads to the liberation in the blood stream of iron and of melanin, he tried to demonstrate the presence of antibodies against these substances in the blood of malarial subjects. Using as antigens an albuminate of iron in the form of "Methafer Bouty," and melanin derived from ox retinae, he considered that he had been able to do this. Adida⁵ in 1929 repeated Henry's work and reported very favourably on it as a means of diagnosis of malarial infection. The test has since received a certain amount of attention; Greig, van Rooyen, and Hendry¹¹ and Wiseman¹² have been unable to agree with Henry's postulates as to the nature of the test, but appear to think it may have some use in the diagnosis of malarial infection.

Apart from the case of Grubb⁶ in which infection was conveyed from a recipient who was actually suffering from malaria to the donor, all recorded cases of the transmission of malaria by means of transfusion have been from subjects not known to be suffering from the disease. In those recorded by Oehlecker,⁷ Schnitzler,⁸ Mayanz,⁹ Harvier and others,³ and Nobécourt,¹⁰ and in the case reported above the donors were unaware that they had ever had the infection. In those of Oehlecker, Nobécourt, and Harvier the donors, while resident in malarial districts, had regularly taken quinine.

The evidence as to the existence of malarial infestation in the blood of those who never knew they had suffered from the disease is irrefutable. It is probable that a latent infestation in course of time dies out, but it is at present difficult to set a term to its persistence. In Nobécourt's case a donor who did not know he had had malaria, and had left the region of endemic malaria in 1924, infected a recipient in 1931.

The facts make it clear that anyone who has resided in regions in which malaria is endemic is a potential carrier of the parasites, and that the use

of such persons as donors is fraught with risk to the recipient. The reaction of Henry is still in the experimental stage, and until some reliable means of identifying latent infection is available it seems advisable not to use donors who have lived in districts where malaria is endemic.

Clinical and Laboratory Notes

TECHNIQUE OF VARICOSE VEIN INJECTIONS

By M. J. BENNETT-JONES, M.Ch. Liverp.,
F.R.C.S. Eng.

RESIDENT SURGICAL OFFICER, LIVERPOOL ROYAL INFIRMARY;
HONORARY SURGEON TO THE BOOTLE GENERAL HOSPITAL

AFTER surveying large numbers of patients who have had varicose vein injections, I am convinced that unsatisfactory results are chiefly due to bad technique. I have come to the conclusion that the majority of varicose vein injections are still given with the patient standing, because it is easier to introduce the needle in this position. Colt, Ramsay, and Morrison,¹ however, say that when one hears of patients with enormous varices being injected in the standing or sitting position it is evident that there is a lack of appreciation of the principles concerned. I would like to go further than this by condemning all varicose vein injections given in the standing position, and I will describe a satisfactory "empty vein" technique that can be used in all cases.

DISADVANTAGES OF INJECTIONS INTO DISTENDED VEINS

The first disadvantage of the standing position is the dilution of the sclerosing solution with the large amount of blood in the vein. This point has often been raised, but many still think that this can be overcome by using larger amounts of stronger sclerosing solutions; this is apt to be followed by a very severe localised reaction. The other disadvantages of injections into distended veins result from the high venous pressure; I do not think this point has been sufficiently emphasised. The high venous pressure causes extravasation of the sclerosing solution into the perivenous tissues, and often causes a perivenous cellulitis at the site of the injection; it has even caused an injection ulcer,² although the injection was given intravenously. A varicose vein already has impaired elasticity, and also probably excessive permeability of its endothelium; it is rational to assume that the venules of the vasa vasorum are also dilated and more permeable. In the injection treatment it is therefore advisable to assist the contraction of the vein as much as possible, in order to obtain the "stiction" effect, and yet to

avoid excessive reactions and liability to necrosis of the vein. These desirable effects have been found to be best produced by using an empty vein technique.

EMPTYING THE VEIN

Without an Esmarch's bandage it is impossible to produce an absolutely empty vein, but the more the limb is elevated the more empty do the veins become, and the degree of emptiness produced by this method is sufficient.

Attempts have been made to empty veins by complicated apparatus. Schmitt³ used a double-barrelled syringe, after placing a proximal and distal tourniquet on the segment of the vein to be injected. He "emptied" the vein with one syringe, and injected the sclerosing solution with the other. Nobl⁴ also used two constricting bands on the limb. The difficulty, however, lies in the presence of communicating veins, which allow a superficial vein to fill although it is occluded at both ends. Colt⁵ has mentioned that during varicose vein operations, bleeding occurs from the communicating veins: these operations were performed with the leg horizontal or slightly elevated, so more elevation is required to stop the flow.

Steubner⁶ realised how important it was not to inject a varicose vein with the patient standing, although he used the erect posture for the needle insertion; he devised accordingly a special table to enable the change in posture to be made. His method has serious drawbacks. First, it involves cumbersome apparatus and is therefore unlikely to be widely accepted; secondly, the needle may slip out during the change in position; and thirdly, the limb can only be elevated to the horizontal position.

TECHNIQUE

Having decided that a well-elevated limb is best for injection, it is necessary to have a simple, certain method of producing at first a distended vein for the introduction of the needle, and then a collapsed vein for the injection, with the limb elevated the whole time so that there is no change in position. The basis of the technique is that a pneumatic tourniquet, inflated to a pressure of 180 mm. Hg, is sufficient to occlude all the veins of the lower limb, including the deep ones, so that the superficial veins remain distended when the leg is well elevated.

An ordinary sphygmomanometer is placed on the lower third of the thigh with the patient standing, chiefly on the other foot so that the thigh muscles are relaxed, and the tourniquet is inflated to 180 mm. Hg pressure. He then lies down on a couch, with his chest slightly supported, and the affected leg is raised on a box. The first injection is given at the periphery. When the distended vein has been entered, the pressure in the tourniquet is easily released with the left hand. Before injecting the solution it is advisable to wait until the veins visibly collapse. When the needle is withdrawn it is usual to apply temporary pressure, but it will be observed that the puncture does not bleed as it invariably does when veins are injected in the standing or even horizontal position. The limb should remain raised until an Elastoplast bandage has been applied.

I have found, like many others,¹ that 30 per cent. sodium salicylate solution is the most reliable of the common sclerosing agents, while the very few refractory cases invariably respond to 10 per cent. sodium morrhuate.

RESULTS OF TREATMENT

By this technique the number of injections required to cure a patient has been much diminished, although the dose of 30 per cent. sodium salicylate has been

4-5 c.cm. for an average case. Excessive reactions have, however, been more infrequent and trouble at the site of the injection has become unknown.

By comparing similar cases, I think that injections starting at the periphery with this technique yield better results than internal saphenous vein ligation followed by injections. A cramp-like pain in the leg after salicylate injections is the only real disadvantage, but this is not severe enough to discontinue its use until the discovery of another solution that is painless and as reliable. Fainting occurred in two patients immediately after injection, but an excessive dose was given in one and probably also in the other; both patients were quite fit within five minutes, and they both obtained excellent results. If the injector is afraid of the solution entering the general circulation, and he wishes to use larger doses of solution, the tourniquet can be again quickly inflated to 180 mm. Hg pressure as soon as the veins have collapsed, so that the sclerosing solution is loculated in the veins; this addition to the technique is only required for the largest veins. Slow-injection is apparently a sufficient safeguard in the majority of patients, if moderate doses are given.

SUMMARY

(1) The advantages of an "empty vein" technique are stressed. (2) A simple effective technique is described, which I hope will be useful to a wider circle of vein injectors.

I wish to thank the staff of the Liverpool Royal Infirmary for permission to treat their cases, and the successive house surgeons, who have also carried out the technique in a large number of cases.

RUPTURE OF UTERUS WITHOUT SYMPTOMS

By I. H. K. STEVENS, M.D., M.R.C.P. Lond.

HON. ASSISTANT PHYSICIAN TO THE KENT AND CANTERBURY HOSPITAL; CONSULTING OBSTETRICIAN TO THE COUNTY BOROUGH, CANTERBURY

IN the following case a woman carried on her normal occupation of housewife for six weeks after rupture of the uterus.

Mrs. B., aged 39 years. It was her seventh pregnancy; five children had been born alive and there had been one miscarriage. The fifth child was delivered by Caesarean section, which was performed for central placenta praevia on Nov. 23rd, 1929. The last menstrual period in the seventh pregnancy began on March 10th, 1935. The estimated date of birth was, therefore, Dec. 18th-20th, 1935, but no child was then born; some pains were felt, actually between these dates, but they were not very marked and they passed off again. There was no dilatation of the cervix and it was thought by her doctor that there had been a mistake about the dates, as the uterus did not appear to have reached the size of a full term pregnancy. The woman remained at her work as a housewife and was first seen by me on Jan. 30th, 1936, as it was now considered that there was a possibility of post-maturity, even if there had been a mistake of a month in the dates.

On examination the patient did not seem to be in any way unwell. Temperature, 98° F.; pulse, 84; blood pressure, 134/76 mm. Hg. Abdominal examination revealed a pregnancy, by size about 34-36 weeks, and

there was some tenderness on palpation. The foetus was in the right sacro-anterior breech position. No fetal movements were observed and no fetal heart sounds could be heard. On vaginal examination there was a slight reddish-brown sanious discharge, said to have been present since Dec. 20th. The cervix was small and firm; there was no dilatation. No presenting part of the foetus could be felt, and no definite opinion as to the condition of the body of the uterus could be formed owing to tenderness and rigidity.

The patient was removed to hospital with a view to further investigation and termination of the pregnancy. No satisfactory evidence could be obtained of the previous Caesarean section, but questions to the patient elicited the fact that the puerperium had been complicated and followed by severe illness. Examination of the urine showed specific gravity 1030. No albumin or other abnormality.

X ray examination confirmed the presence of a foetus; the report was as follows: presence of foetus, skull collapsed.

In view of the history it was decided to operate to remove the foetus and if necessary the uterus.

At operation.—The abdomen was opened by Mr. A. B. Beresford-Jones by a subumbilical midline incision. On opening the peritoneal cavity the foetus was found to be lying free and was removed: the lie was transverse with the head towards the left. The intestines were matted with vernix caseosa. The uterus was about the normal size in a multipara; there was a long rent in the anterior wall of the uterus which was removed by total hysterectomy. There was no blood or organised blood-clot in the peritoneal cavity. The peritoneum was sutured over the

vaginal stump and a drainage-tube stitched into the vagina. The abdomen was closed without drainage.

Progress.—After a brief rise of temperature to 100.4° F., on the day following the operation, the patient made an uninterrupted recovery and was discharged in good health.

Examination of foetus and placenta.—The foetus was macerated and covered with vernix caseosa. The fingernails were fully developed and it therefore appeared to be a full term pregnancy; the weight was 4 lb. The placenta was found lightly adherent to the uterus, near the ruptured scar. It was shrunken and thin, 4½ in. in diameter; the total weight with umbilical cord was 7 oz. There was no sign of an extra-uterine attachment.

The uterus had undergone complete involution. There was a rent in the anterior wall, presumably through the scar of the previous Caesarean section, about three-quarters of the whole length.

In my opinion labour occurred between Dec. 18th and 20th, 1935. During this the uterus ruptured through the old Caesarean scar and expelled the foetus and placenta into the peritoneal cavity. This is verified by the condition of the uterus, placenta, and foetus as well as by the progress of the case as described above. Six weeks later the woman was apparently in normal health, with normal temperature and pulse-rate. She had complained only of slight abdominal discomfort and an intermittent blood-stained discharge. There was no evidence that she had suffered from hæmorrhage or shock and she made a complete recovery from the operation.

SPONTANEOUS SUBLUXATION OF THE ATLANTO-AXIAL JOINT

By JUDSON T. CHESTERMAN, M.R.C.P. Lond.,
F.R.C.S. Eng.

SURGICAL REGISTRAR, SHEFFIELD ROYAL HOSPITAL

THIS condition still seems to be of sufficient rarity to report, for I believe only about 25 cases have been placed on record.

Case-history.—The patient was a girl, aged 10, admitted to the Sheffield Royal Hospital on August 4th, 1934, complaining of "stiffness of the neck." She had been perfectly healthy until February, 1934, when during confinement to bed for an attack of acute tonsillitis she

developed stiffness of the neck—a condition which had been slowly becoming worse ever since.

Examination.—Positive findings were: head held forward and to the left, also slightly downward, but can be turned to the right with an effort; no tenderness, muscle wasting, or spasm, no glands or tumour felt; limitation of movement of the head upon the shoulders in all directions. Radiography on August 8th showed displacement of the first cervical vertebra on the second (Fig. 1).

Treatment.—For two months the child was kept lying flat with extension applied; afterwards she was sent home with a Jones's collar which was worn for five months. When she was seen on Sept. 27th, 1935, there was no deformity or limitation of movement and she was in perfect health. Radiograms showed satisfactory reduction and calcification (Fig. 2).

Watson Jones¹ points out that the condition is due to hyperæmic decalcification of the atlas, with loosening of the ligaments attaching the odontoid process to the atlas, consequent upon nasopharyngeal or other infection at the base of the skull. Clinically three groups are met with: (1) dislocation with pressure on the medulla causing immediate death; (2) subluxation with pressure on the cord giving rise to quadriplegia; and (3) the common group of which the above is a typical example.

I wish to thank Mr. J. B. Ferguson Wilson for allowing me to report the case and Dr. J. L. Grout for the radiograms.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF MEDICINE

At a meeting of this section held on Feb. 25th the chair was taken by Dr. H. MORLEY FLETCHER, vice-president. Dr. G. W. PICKERING opened a discussion on

Obliterative Arterial Disease

as it affects the limbs. The chief clinical types, he said, were thrombo-angiitis, degenerative, senile, and diabetic forms, and embolism—which all affected arteries of any size and caused loss of pulse. Raynaud's disease with necrosis affected small arteries. All these forms except embolism were progressive, but a sudden single attack might occur in small arteries at the extremities in the bilateral gangrene of the young, of the aged, or of paroxysmal hæmoglobinuria. The term "Raynaud's disease" should be restricted to the spasmodic type due to over-reaction to cold in small limb vessels. In severe cases the vessels became progressively obliterated. The outstanding problem was the nature of the factors determining the oblitative process. Only in the vascular complications of cervical rib could the process certainly be arrested. There was no evidence that any form of treatment materially influenced the course of the disease in other types. The condition could be recognised by intermittent claudication: a constant, aching pain felt in a muscle, induced by exercise and nothing else, and relieved by rest. This pain was due to the accumulation of chemical substances which normally were removed by the circulating blood, and might appear in severe anæmia, but otherwise was pathognomonic of structural disease of the vessels. Other diagnostic indications were gangrene (which, in the absence of physical chemical or mechanical destructive agents, was also an absolute indication), absence of arterial pulsation in a warm limb, skin temperature, and the reactive hyperæmia test. The skin temperature was first measured under ordinary environmental conditions, and in oblitative vascular disease the affected limb was cooler than the other. This, however, might be found in other conditions, including hysteria. Any disused limb was likely to be cold. The temperature was measured again after removal of vasomotor tone by spinal or sympathetic nerve block or by warming the body. A difference of several degrees might then be found between the two limbs, and a typical curve was pathognomonic if there were no indication of interference with the sympathetic nervous system. With a little practice a very fair estimate of skin temperature could be made with the hand. The reactive hyperæmia test was in many ways the best, being delicate and simple. The limb was first warmed in a bath, raised to let the blood flow out, and the circulation abruptly stopped with a sphygmomanometer cuff. Then the limb was kept warm in the bath for about five minutes and the cuff abruptly released. In the normal limb or one with spasm the blood flowed rapidly back to the skin. In oblitative vascular disease the skin just below the cuff flushed in three or four seconds; about ten seconds later blood might creep into the calf, and finally, but slowly, to the digits. The test gave an indication of the lowest level for amputation. The blood-flow could be increased by sympathectomy, which was the only

permanent method; by vasodilator drugs and heat—which were disappointing; by warming the body; and by suction and pressure therapy. Heating a limb increased metabolism and so might increase blood-need more than blood-flow. Suction and pressure applied alternately seemed to be a promising measure. It gave less satisfactory results in the presence of extreme occlusion, massive gangrene or slough, severe infection or dermatophytosis, and osteomyelitis. The only contra-indications were encapsulated pus and severe infection. The main place of temporary measures lay in tiding over the time between obliteration and the opening up of collateral vessels.

THE SURGEON'S CONTRIBUTION

Prof. J. PATERSON ROSS described experience with this condition at St. Bartholomew's Hospital. The symptoms were different according to whether the obliteration was in the terminal vessels or higher up. In the former case the chief symptoms were pain and gangrene. If the pulse were absent in the dorsalis pedis and posterior tibial arteries the case was usually one of diffuse arterial disease with accompanying obliteration higher up—notably in senile and some diabetic patients. The only treatment was amputation above the knee. When the pulses were present it was a little difficult to understand the lesion. Some of the patients were diabetics. Sometimes there was disease of the popliteal artery insufficient to obliterate it. Surgery should be avoided as long as possible in these cases where only a single toe was affected, and should be as conservative as possible. The pain was sometimes present before gangrene and was an expression of poor nutrition in the skin and subcutaneous tissues. It was relieved by anything which improved nutrition. Sympathetic ganglionectomy was usually successful. Obliteration of the main vessels was associated with intermittent claudication and severe pain in the leg. Lumbar ganglionectomy for claudication gave disappointing results. The pain in the calf might be dramatically sudden in onset and might appear after an apparently successful ganglionectomy. The removal of a thrombosed portion of the artery had been known to relieve it. Arteriography had given accurate information about the vessels, notably in showing the frequency of atheroma in the popliteal artery.

Mr. A. M. BOYD showed a series of arteriograms illustrating the help given by this method. Localised disease of the popliteal artery, he said, could be discovered by no other means.

THE PATHOGENESIS

Prof. H. M. TURNBULL reported on 112 amputations for gangrene, 95 having been done for atheroma and 17 for thrombo-angiitis obliterans. The majority of the atheroma cases had been associated with medial calcification and a few with medial fibrosis. There had been nearly 40 per cent. females, and all the patients had been aged. In the intima there was a great increase of the hyperplastic layer, and some degeneration—sometimes calcification but often fatty atheroma. This increase of the intima could reduce the lumen to a small canal and form a sort of new vessel round it. That alone was often enough to produce gangrene. Total occlusion might be produced by fatty atheroma: imbibition of the intima with lipid. A commoner way was organisation of

a thrombus. The condition was so widespread that a collateral circulation seemed almost impossible; no healthy arteries were available. In thromboangiitis obliterans males were in the great majority; the average age was much younger (31-56), and often the patients were diabetic. There had been no necropsy in this series, and the study of amputated limbs was unsatisfactory. It appeared, however, that the obliteration by organised thrombus began in small arteries and proceeded towards the heart. There was always evidence of inflammation, but this did not imply that inflammation preceded thrombosis. There had been little or no evidence of adventitia inflammation or of intimal cushions as a basis for thrombosis in smaller arteries. In larger vessels the intima showed thickening, vascularity, and a delicate collagenous stroma—an extension of the inflammatory reaction organising the clot. It also showed in most cases large areas of hypertrophy in the popliteal artery and its branches, forming great cushions, but this process did not, probably, give rise to thrombosis by itself. The cushions were degenerate areas of hypertrophied intima, probably formed secondarily to obstruction in the smaller arteries. In two cases there had been endarteritis fibrosa, but no associated thrombosis. The veins showed a focal or general intimal hypertrophy, but that might be an adaptation to a reduced flow and was also seen in the smallest arteries.

DISCUSSION

Dr. PARKES WEBER said that the causes of thromboangiitis obliterans were not known. A constant problem was whether or not to stop all use of tobacco; it seemed that smoking played a part and absolute abstinence at an early stage might just make the difference.

Dr. OTTO LEYTON found it hard to believe that gangrene was never due to spasm, and quoted a case where spasmodic gangrene had occurred in a diabetic. He recalled successful Symes' amputations for gangrene of the toes, although at the operations no ligatures had been necessary. He doubted whether a pulse were always lost before intermittent claudication.

Dr. J. D. ROLLESTON referred to the rare cases of obliterative disease after infectious fevers. Gangrene of the leg had followed diphtheria in two cases, and fatal double gangrene of the legs had followed measles once in his experience.

SECTION OF UROLOGY

At a meeting of this section on Feb. 27th, with Mr. R. OGIER WARD, the president, in the chair, a paper on

Horseshoe Kidney

was read by Mr. R. H. O. B. ROBINSON. He said that the incidence of horseshoe kidney in cases of renal disease was 1 in 125. Male patients preponderated over females in the proportion of 8 to 3. The U-shaped mass lay lower than the usual kidney level, and the pelves lay anteriorly because normal rotation could not occur. The mass was heavier than two normal kidneys. Lower pole fusion was commoner than upper pole fusion. In upper pole fusion the suprarenals might also be fused, and this should be borne in mind if extirpation of a part of the kidney was contemplated. There was usually one artery to each half, and one artery to the isthmus. Radiographically the lower renal poles were invisible, the pelves low, and the inferior calices on one or

both sides lay internal to the ureter. The minimal basal angle ranged from 60°-90° in the normal radiogram, with an average of 90°. In horseshoe kidney it was reduced, and in his series averaged 57°. The ureters showed a "flower vase" arrangement, each having a slight S-shaped bend so that together they outlined the contours of a vase. Mr. Robinson showed a series of radiograms of the condition, in which the pelves were seen to be low, often elongated, and bizarre in shape, and the reduction of the minimum basal angle was demonstrated. The complications, he said, were obstruction to outflow of urine, with the development of hydronephrosis and pyonephrosis or calculi; or the horseshoe, like the normal kidney, might be involved by tuberculosis or tumour formation. The condition required no treatment per se. In Thompson's 19 cases only 3 showed renal disease. Pain was a fairly common symptom. Abdominal tumour was not a prominent physical sign; statistics showed its presence in 30 per cent. of cases. In performing heminephrectomy the first step was to tap a hydronephrosis or remove calculi if present. Later the kidney could be approached extraperitoneally from the lateral position and the isthmus divided between clamps. Horseshoe kidney was probably comparatively common and could be diagnosed by routine pyelography.

In the discussion which followed, Mr. A. RALPH THOMPSON said that in some cases unilateral kidney was really a variety of horseshoe kidney. In the latter condition the fused kidney level prevented from rising to the normal kidney level by the inferior mesenteric artery; if it did succeed in rising it was forced to go to the left side, and then had the form of a solitary kidney with two ureters. He thought the term "fused kidney," which covered this condition, should be preferred to "horseshoe kidney" which did not.

Mr. F. MCG. LOUGHNANE described a case in which he had divided the isthmus of a horseshoe kidney through a right loin incision, and fixed the right kidney but not the left by nephropexy. Subsequently there was leakage of urine from the right kidney through the wound; this was eventually stopped by diathermising the sinus. He now considered that a second incision should always be made in these cases in order to fix the left kidney as well as the right lest leakage of urine from the left kidney into the tissues should occur and cause disaster.

Mr. H. A. M. WHITBY described a case in which it had been necessary to remove the left half of a horseshoe kidney in a youth of 17; the patient had died of peritonitis on the eighth day.

Sir W. DE COURCY WHEELER had performed heminephrectomy of a tuberculous horseshoe kidney, the anatomical condition being recognised during the operation.

Mr. JOHN EVERIDGE had seen two cases of ruptured horseshoe kidney in one month, and in both he had sutured the ruptures and avoided heminephrectomy. Rupture was probably not an uncommon accident to a horseshoe kidney; a jar on the abdomen might be sufficient to cause it, because the kidneys were fixed by the isthmus. He thought it would be wise nowadays to divide the bridge by endothermy to avoid hæmorrhage.

Mr. T. J. MILLIN contributed a paper on the Surgical Treatment of Impotence

He said that inability to produce erection might be due to: (1) congenital or acquired abnormalities of the external genitalia; (2) systemic disease; (3) neuro-

pathies; (4) endocrine disorders; (5) neurasthenia; (6) functional causes; or (7) it might be transitory as a result of prolonged abstinence. Three other conditions might be responsible for the disability—namely, trauma of the perineum, inflammation of the perineum, and premature senility (occurring between 40 and 50 years of age). Physiologically erection depended on either psycho-sensorial or cutaneo-motor reflexes, and involved cerebral, lumbar, and sacral nerve centres. Lowsley in New York had experimented by ablation and by plication of the bulbo- and ischio-cavernosus muscles in dogs, and had found that the power of erection was considerably influenced by the action of these muscles. He had then tried the effect plicating these muscles in man. The operation was performed with the patient in the lithotomy position and a bougie was passed into the urethra. The bulbo-cavernosi muscles were plicated and the ischio-cavernosi approximated towards the midline by means of ligatures of chromicised ribbon catgut. In Lowsley's series complete success had followed the operation in 9 cases of 14. In his own series of 8 cases there were 4 complete and 2 partial successes. The cases should be selected and those with a neuropathic history excluded.

Mr. A. E. ROCHE described a case of impotence following rupture of the urethra in which the disability had possibly been of psychological origin.

Mr. WHITBY recalled a patient who had been impotent for 15 years following rupture of the membranous urethra by a shell wound during the war. He had treated this man by diathermy to the spine and rectum, orchitic injections, and suprarenal extract. After two years erection had been re-established.

Mr. THOMPSON quoted cases illustrating that epispadias and hypospadias were not necessarily associated with impotence.

Mr. V. W. DIX wanted to know whether the four successful cases in Mr. Millin's series had been exposed, before operative treatment, to the vigorous influence of Mr. Millin's personality.

Mr. MILLIN replied that the two cases he had treated before operation had both been failures.

The PRESIDENT said he had seen some of Lowsley's work in New York, and believed that Lowsley claimed that the operation was only useful in cases where there was impotence due to injury of the perineum.

A discussion on

Steinach II. Operation for Prostatic Obstruction

was opened by Mr. A. ELLIOT-SMITH, who said that that this operation consisted in bilateral ligation of the efferent ducts of the testicle as they passed to the globus major of the epididymis. Ligation of the vas deferens (Steinach I.) was liable to produce swelling and tenderness of the epididymis, from collection of testicular secretions. The Steinach II. operation occluded the testicular ducts before they reached the epididymis, and the tunica albuginea prevented undue swelling of the body of the testicle. Dr. Paul Niehans, of Clarens, was the first to use this operation for prostatic obstruction.¹ Local anaesthesia was used and a silk ligature was passed round the digital fossa of the epididymis so as to occupy the groove between the globus major and the body of the testicle. Mr. Elliot-Smith had himself performed the operation on 20 cases, but had lost sight of 2 after two and three months respectively.

¹ See THE LANCET, Feb. 8th, 1936, p. 307.

Of the remaining 18 patients, 3 had died and 15 had left hospital with fairly good control of micturition; 2, however, had had a recurrence of prostatic obstruction 8–10 months later and had been treated by prostatectomy. Sixteen patients in the series had been admitted with acute retention, and of these 9 had had persistent retention over periods varying from ten days to five weeks; 5 of these passed urine normally on the day of the operation and the other 4 passed urine on the second, fourth, seventh, and thirteenth day respectively. Two patients in the series were admitted with suprapubic cystostomies. Although normal micturition might begin soon after the operation, it was quite usual for the residual urine to exceed the amount passed naturally for the first week. In the absence of infection, the residual urine of his cases had come down to 1 or 2 oz. over periods varying from one week to five. Difficulty in starting the act of micturition seemed to be abolished once normal micturition had begun. Some degree of frequency might persist. Having examined his old cases, he was convinced that there was a definite decrease in the size of the gland following operation. Thirteen cases in his series of 18 had been relieved by the operation and were still under observation, the periods since operation ranging from one month to eighteen.

Mr. H. P. WINSBURY WHITE described a case in which the residual urine had amounted to 18 oz. on the day before operation. Following the operation the patient developed acute retention leading to uraemia. A catheter had been tied in until he had passed the crisis, and the residual urine was now down to 4 oz. and the patient was progressing favourably.

Prof. G. GREY TURNER had seen Mr. Elliot-Smith's cases and had been much impressed. He thought the method deserved thorough trial.—Mr. A. CLIFFORD MORSON asked what was the pathological nature of the prostatic obstruction treated by Mr. Elliot-Smith.

Mr. DIX asked whether there was any advantage in Steinach II. over the Steinach I. operation, in which the vas deferens was ligatured or a part of it was excised. Did ligation of the vas really cause any tenderness of the head of the epididymis?

Mr. EVERIDGE said that patients with incipient prostatic symptoms were beginning to make inquiries about this operation. Some investigation was necessary to find out whether operation on these younger patients was desirable.

Mr. J. G. YATES BELL said that many surgeons ligatured the vas before performing suprapubic cystostomy, as a safeguard against epididymitis. If there was no danger of such infection occurring, Steinach II. might be adopted instead of Steinach I. as a preliminary to the operation.

Mr. JACOBS said he thought that Steinach II. was not suitable in all cases of prostatic obstruction, and described a case in which there had been improvement in frequency following the operation, but in which the residual urine had increased in amount, and suprapubic cystostomy had become necessary owing to the onset of uraemic symptoms.

Mr. S. I. LEVY mentioned two patients who had become more vigorous and active following Steinach II. operations, and also, according to the nurses, younger looking. On the other hand, a patient of 80, on whom he had operated the day before, was now seeing elephants and robbers.

Mr. LOUGHNANE asked what was the effect of the operation on kidney function, and Mr.

E. W. RICHES reminded the meeting that cases of prostatic obstruction often showed fluctuation of symptoms. After an attack of acute retention a patient might remain well for years. The renal function should be thoroughly investigated before and after the operation.

Mr. ROCHE suggested that both Steinach I. and II. might be performed as a preliminary to the suprapubic operation.—Dr. HEY remarked that Dr. Niehans claimed that Steinach II. was advantageous in cases of carcinoma of the prostate.

In replying, Mr. ELLIOT-SMITH said that spermatogenesis was believed to be diminished by Steinach II., and that this gave it an advantage over Steinach I. He had seen no epididymitis in his cases but agreed that both operations might be done as a safeguard before a suprapubic cystostomy. He had noticed no mental changes in his patients. All the prostates in his series were large, not small and fibrous. Two, removed post mortem from patients who died, showed a decrease of epithelium and an abundance of the fibrous elements.

MEDICO-LEGAL SOCIETY

At the meeting of the society held at Manson House, Portland-place, on Feb. 27th, Mr. C. AINSWORTH MITCHELL, D.Sc., the president, being in the chair, Mr. H. W. LINSTAD read a paper on

Statutory Safeguards against Poisoning

with special reference to the work of the Poisons Board. He said that according to the Registrar-General's report 892 persons died in Great Britain from poisoning in 1934, the average annual number for the last ten years having been 815. He proposed to indicate some of the causes of those deaths, the statutory safeguards provided in the Pharmacy and Poisons Act, 1933, and the recently made rules. Hitherto the duty of deciding what substances should be subjected to statutory control had been vested in the Council of the Pharmaceutical Society, and a Departmental Committee, reporting in 1926, testified to its honourable and distinguished service. But it was thought undesirable that such an important duty should be carried out otherwise than by a Minister responsible to Parliament. The Home Secretary was advised on the rules to be made under the Act by the Poisons Board, who had also prepared the Poisons List. The List and Rules were now before Parliament.

Misuse of poisons, said Mr. Linstead, was classifiable under the three headings: suicide, accident, criminal poisoning other than suicide.

The extent to which *suicide* could be prevented depended on whether it was premeditated or committed because of means readily at hand to carry out a sudden impulse. The Departmental Committee had endeavoured to ascertain whether the easy accessibility of coal-gas caused persons to commit suicide who would not otherwise have done so. In favour of this supposition was the considerable increase of the rate of suicide among females of recent years, the increase being entirely in coal-gas deaths. The Committee were agreed, at any rate, that the publicity given to cases of suicide by poisoning had been the cause of the adoption of this means through suggestion and imitation, and therefore recommended a drastic statutory limitation of the publicity given in newspapers to inquests on suicides.

Apart from coal-gas, lysol and hydrochloric acid were most commonly used by suicides in the proportion respectively of 1000, 300, and 90 per year. There were now available less toxic substitutes for the two latter substances: halogenated phenols were coming into use as disinfectants, and non-toxic powders for domestic purposes. It was therefore regrettable that the Home Secretary, against the recommendations of the Poisons Board, had permitted both lysol and hydrochloric acid to be sold by any trader who successfully applied to the local authority to have his name added to the list of poison sellers. Though aspirin had been used as a means of suicide the evidence as to its danger did not seem to warrant the scheduling of this drug as a poison. The Poisons Board had directed attention to the need for greater control over the derivatives of barbituric acid. Each of the many analogues of Veronal had been termed the safe hypnotic, yet each in turn found its way into the statistics of deaths from poisoning. Though fatalities from this group of drugs had increased during recent years the total number was not yet large. For the tighter control of these drugs the new legislation provided that they should be supplied to the public upon medical, dental, or veterinary prescription only, the prescription being valid for one occasion only, unless the prescriber ordered repetition. The new legislation contained few provisions which were likely seriously to decrease the use of poison for suicide, and the greater availability of lysol might be reflected in an increase in the suicide figures from this poison in the coming years.

Accidents were liable to occur wherever poisons were used. For example, halogenated derivatives of carbon, such as carbon tetrachloride and di- and tri-chlorethylene, both widely used as industrial solvents, might have toxic effects. Continual inhalation of these vapours caused toxic jaundice. The Poisons Board had suggested that it might be desirable to require the labelling of the containers of these substances with a warning of the character of the contents, and the precautions to be taken in using. The manufacture of pharmaceutical preparations containing poisons had nowadays to be undertaken by or under the supervision of a pharmacist, a member of the Institute of Chemistry, or a person who for a period of three years before the Rules came into operation had been continuously engaged in the manufacture of such preparations. Certain biological products were allowed to be manufactured by or under the supervision of a medical practitioner. In the past, accidents had occurred due to the sale of such substances as solutions of ammonia, hydrochloric acid, and disinfectants in sauce bottles, whisky bottles, and even milk jugs by traders who kept no poison bottles; this led the Poisons Board to recommend that listed sellers of Part II. poisons should be required to sell those poisons in sealed containers as sealed by the manufacturer. However, the value of this recommendation had been weakened by a modification permitting solutions of ammonia, hydrochloric acid, and salts of lemon to be packed by the listed seller.

The compounding of medicine containing poison was restricted to hospitals, pharmacies, and medical practitioners' establishments. Any person, however small his pharmaceutical knowledge, was allowed to open a shop and undertake the dispensing of medical prescriptions. Nor had we in this country, said Mr. Linstead, adopted the precaution against accidents which existed in most countries on the continent, the reservation to the medical

practitioner of prescribing and to the pharmacist of dispensing. In Scotland there was a convention whereby the medical practitioner did not supply his own medicines. Little could be done by legislation to prevent accidents from poisons occurring in the home; except by labelling and a distinctive shape of a bottle containing poison. The too frequent use of the word "poison," particularly when applied to substances not highly toxic, diminished the cautionary value of the word. For medicine to be taken internally the following words might be substituted: "Caution; it is dangerous to exceed the stated dose." Mr. Linstead quoted one case in which a poison was bought in a poison bottle, but was turned into a milk jug so that the bottle could be returned and the deposit refunded. In another case a fowl was destroyed by strychnine in order to destroy a neighbouring fox; but a farm labourer found the fowl and took it home for the family dinner. The carrying of poisons by railway was carefully regulated to prevent leakage, but, so far, no parallel regulations had existed for carriage by road. Rules to fill this gap had now been made. No general provision was found to be practicable for the more ready identification of poisons.

Two circumstances contributed to accidental poisoning from substances designed for medical purposes, perhaps on medical advice: (1) the idiosyncrasy of individual patients, and (2) the taking for long periods of poisons which had a cumulative effect. The Board had to consider a number of poisons which were known to have caused death or serious impairment of health when taken in medicinal doses. The effect of regular ingestion of acetanilide in producing toxic jaundice had long been recognised, and its use as an ingredient in proprietary medicines had now been checked by including it in Part I. of the Poisons List. Attention was also directed to the part played by pyramidon in producing agranulocytic angina; the Board had imposed a restriction limiting the supply of this drug to a medical prescription, so barring its use in proprietary medicines. The nitrophenols and nitrocresols were liable to produce untoward results, even in medicinal doses, unless the basal metabolic rate of the patient was regularly determined. At least one death had occurred in this country from using such a preparation for slimming purposes. Under the Poisons Rules these preparations might be supplied to the public upon medical prescription only, and steps had been taken to acquaint practitioners with the precautions necessary in the administration of these drugs.

Turning to the use of poisons for *criminal purposes*, Mr. Linstead said that one of the principal objects of the new legislation, as of the old, was to prevent the use of poison for murder, or, at the worst, to facilitate the detection of the murderer. It sought to do this by making the poison difficult to obtain, and the transaction easier to trace by means of a record kept by the seller, and by the label placed on the container. Such poisons as arsenious oxide were now surrounded by numerous restrictions. The registration of all pharmacies by the Pharmaceutical Society and the listing of premises of sellers of Part II. poisons by local authorities would do much to facilitate the task of the police in tracing the supply of a poison by circumscribing the scope of their inquiries. The progressive increase in the delicacy of methods of chemical analysis rendered it very difficult now for a poison used for crime to escape detection. Among the legal aspects of the question was a substantial increase in penalties,

though the maximum fines imposed were not excessive in comparison with those prescribed in similar modern statutes. The rule-making powers conferred upon the Secretary of State by Section 23 of the Pharmacy and Poisons Act, 1933, were very wide, and were such as to discourage any except the most enthusiastic litigant from taking a case to appeal, since any decision could soon be invalidated by a modification in the rules.

DISCUSSION

Sir WILLIAM WILLCOX said that the report of the Poisons Board represented an upheaval of the pre-existing conditions, and it remained to be seen how the new enactments would answer in practice. Some difficulties were to be expected at first. The recommendations of the Board had not been followed implicitly, as some of the enactments had been modified by the Home Secretary. He agreed that the possibility of purchasing lysol and hydrochloric acid from a person who knew nothing of poisons was a danger. One of the great steps forward taken by the Board was in placing under control drugs which on account of their toxic action ought to be dispensable by only medical men and pharmacists. Barbiturates had hitherto been easily obtainable, and yet they were undoubtedly drugs of addiction. The ordinary person was not in danger of becoming an addict, but the neurotic and unstable was very liable to do so. A further important point was that the prescription for these drugs would in future be retained by the dispenser; if the patient was allowed to keep the prescription the restrictive clause would be largely cancelled, as he could run round to various chemists with it and so lay in a good stock. If there was need to repeat the dose, the number of repetitions must be stated, and the pharmacist should register the details. Australia several years ago adopted regulations restricting the use of drugs of the veronal group, though so far they had not stipulated that the pharmacist must retain the prescription. Drugs which had received special attention included the atophan group, which caused toxic jaundice. He was glad to know that in future strychnine was to be prohibited for the purpose of destroying animals; it would be interesting to see whether the substitutes for this purpose would prove efficient.

Dr. JUDAH JONA (Melbourne) said that in Australia the pharmacist was not required to retain the prescription containing a dangerous drug but to cancel it with a large-lettered rubber stamp, so that there was no chance of it being repeated without authority. Patients liked to retain it as a memento of the fee paid to the doctor. Though there were safeguards against repetition, there were none against purchasing large quantities at a single time. He suggested that the time had arrived for an "honest advertisement" Act, a matter in which he would like to see Great Britain take the lead.

Mr. R. L. COLLETT, F.I.C., said one of the difficulties in connexion with this legislation was that the substances concerned were important products, apart from being poisons; they were used in industry in large quantities, also in research and in analytical work. The problem of the Poisons Board had been complicated by the difficulty of ensuring adequate protection to the public without imposing excessive restrictions upon industry and the practice of the sciences. His own experience of the leather industry ten years ago was that of seeing men shovel red arsenic into vats of lime and soda with a wooden spade; those substances were lying on the floor

of the tannery. He congratulated the Board on the reasonable spirit with which they had removed noxious restrictions from industry while safeguarding the public. It was easier to get a rule altered if experience showed it was inadvisable than to establish the restriction in the first place.

Mr. H. E. CHAPMAN said a year or two must elapse before it would be known whether the present system of control would be more effective than that previously in force.

Mr. F. BULLOCH, D.Ph., was glad that the Poisons Board and the Home Secretary did not see eye to eye over some of the enactments. The Board recommended that poisons used for animal medicines and sold as proprietary medicines should be limited to a certain series of poisons; but now, through the action of the Home Secretary, that limitation had been suddenly withdrawn and so the whole gamut of poisons was open to animal medicine manufacturers.

Prof. J. G. WRIGHT (Royal Veterinary College) said that no member of the veterinary profession had a seat on the Poisons Board. He congratulated the Board on their decision regarding the use of poisonous substances in vermin beds; he protested against the use of poison baits which had been indiscriminately laid. Dispatching animals by arsenic and phosphorus meant a miserable death. Morphine was largely used by the veterinarian as a pain reliever, as also was cocaine, which drug had such a more sedative action on the dog's cornea than did any other.

The PRESIDENT thought that if the Poisons Board could be invested with more power than at present, many of the existing difficulties would disappear. As an instance, meta fuel, which had been investigated by Sir William Willcox, Dr. Cox, and himself, ought to be labelled as a poison. It was used in the cinema industry for producing an impression of snowstorms, and was sold in small boxes, looking like sweets, which could be purchased by anybody. It had been eaten as a sweet by accident.

Mr. LINSTED, in reply, said an attempt had been made to get over the formula on the bottle difficulty by requiring disclosure of the usual scientific name on the bottle or packet. He had been glad to learn that strychnine was not necessary as a vermin killer.

SOCIETY OF MEDICAL OFFICERS OF HEALTH

THE maternity and child welfare group of this society held a meeting in London on Feb. 21st with Dr. G. C. M. M'GONIGLE (Stockton-on-Tees) in the chair.

Prevention of Maternal Mortality: the Rochdale Experiment

Dr. ANDREW TOPPING (senior medical officer, London County Council; late M.O.H. for Rochdale) read a paper entitled *Some Factors in Maternal Mortality with special reference to the part played by Publicity in its Prevention*. He began by explaining the alarm and dissatisfaction expressed by the public at the continued high maternal mortality-rate as the psychological reaction to the death of a mother in childbirth, and pointed out that there were other conditions—e.g., diphtheria and acute appendicitis—in which lives were lost in an equally unnecessary manner without arousing any comparable public feeling. In the present situation however there were

certain redeeming features, and it should be noted in the first place that the method of reckoning the rate was in several ways fallacious. Clearly the basis of the rate should be the total pregnancies, and since this was not taken as the basis, and varying factors such as the increase in abortion and the decrease in fertility were not comprehended in it, comparisons both with the past and with other countries were misleading. If these considerations were taken into account the place of this country in the international standard of obstetric efficiency would be near the top instead of, as at present, about half-way up. Again, all recent reports had emphasised that about half the maternal deaths were avoidable, but this classification into "avoidability" was unsatisfactory because, for example, the fatal case of eclampsia which had received no antenatal care was classed as an avoidable death, whereas it was well known that eclampsia occasionally might arise despite every precaution. It was also noteworthy that this basis of 50 per cent. of avoidable deaths was largely taken from areas in which the maternal mortality-rate was high. In areas in which the rate was low far less than 50 per cent. were avoidable.

When he had first taken up antenatal work in a metropolitan borough Dr. Topping had been struck by the intense interest taken by pregnant women in their condition, and had found them eager to coöperate if the reasons for their coöperation were intelligently explained. When he moved to Lancashire he found that the health visitors employed by the Lancashire county council were exceedingly good and careful in instructing the mothers in the various practical details of the hygiene of pregnancy and confinement. At Rochdale the maternal mortality-rate was much higher than in the surrounding districts in which the Lancashire health visitors worked, and in fact it had been for some years the highest in England. His first task was to interview the practitioners, many of whom he had come to know personally, and from these he received many suggestions about possible causes of the high rate, such as rickets, malnutrition, and industrial work. A study of the forms of investigation into maternal deaths convinced him, however, that none of these reasons held good and that the two main factors were lack of antenatal care and unnecessary interference.

The first step in the campaign was to hold a meeting of the medical, social, and religious bodies in the area. There was a large attendance, aided perhaps by the provision of a dinner by a generous supporter, and a publicity campaign was decided upon. Numerous meetings were then held averaging about twice weekly, addressed by Dr. Topping himself, his maternity and child welfare medical officer or other doctors. No alarming propaganda was indulged in and it was emphasised that pregnancy was a normal natural condition which was perfectly safe if the mother did her share. Mothers were urged to accept antenatal care, to report the slightest abnormality at once, and to accept in-patient treatment if recommended. They were told that half the maternal deaths were preventable and that the rate in Rochdale could quite easily be lowered. Pamphlets were distributed in which the main causes of death and how to avoid them were simply explained—i.e., disproportion, abnormal presentation, "kidney weakness," and puerperal fever. "Don't listen to grandmother but visit our antenatal clinic and give yourself and your unborn baby a square deal" was the sort of slogan used. The local newspaper

gave valuable help by printing everything submitted by the health department in exactly the form in which it was received and without scare headlines. The local medical and midwives associations coöperated handsomely, and without their help the scheme would have been unworkable.

At the same time certain improvements and enlargements were made in the antenatal clinics. A few criticisms of the work at these clinics were heard, the usual one being that the medical staff of the clinics took no share in the actual confinement. This was dealt with by publicity suggesting that the criticisms would be more valid if their authors performed their antenatal work properly, and the criticism was also partly met by sending a full report of the antenatal examination to the doctor or midwife concerned whether any abnormality was found or not. On the reverse side of the form of report was a space for the details of labour and puerperium to be noted and returned to the public health department. Other steps taken were the appointment of a consultant, the provision of a unit for puerperal sepsis, and the drawing up of plans for a new maternity home. In addition the ten best midwives in the town were guaranteed an income a very little more than their previous average income, and telephones were installed in their houses; this ensured their coöperation, gave them a definite status, and softened their regret if one of their cases was admitted to hospital. Nearly all these measures, said Dr. Topping, had been taken by most boroughs, although sometimes the letter rather than the spirit of the recommendations had been carried out. The only difference in Rochdale lay in the intense propaganda; for example, the mothers quickly came to know what a real antenatal examination connoted and any doctor or midwife who scamped it was very soon talked about very much to his or her disadvantage. Again, the pressure to interfere from the patients and their relatives was enormously reduced and the routine use of forceps fell very greatly.

The publicity campaign was begun in 1931. The average maternal mortality-rate for the four years 1928-31 was 9.0 per thousand; for the four years 1932-35 it was 3.0 per thousand (1.75 in 1935); and it was, therefore, fairly safe to conclude that these results were due to the campaign. Propaganda based on the truth could do nothing but good. The secret was complete honesty: "tell the mothers why they should do what is wanted and they will do it."

FACTORS IN MORTALITY

Responsibility for maternal deaths might lie with any one or more persons—e.g., the patient, the midwife, the doctor, the hospital, or the local authority. As far as the patient is concerned certain factors were not her fault, so to speak, and comparisons between different areas might therefore be fallacious. For example, he had lately been investigating the reasons for the differing rates in the East End and West End of London and had found that the proportion of primigravidae and the age of the first pregnancy were higher in the West End. Another factor was the variation in the illegitimacy rates, it being known that the maternal mortality for illegitimate births was considerably greater than that for legitimate. Again, hospital accommodation clearly varied enormously, and the figures of various hospitals and organisations were not necessarily comparable, largely because of the selection of cases.

As far as the patient was concerned the apportionment of blame was very difficult. The fact of

pregnancy was still often concealed, sometimes because of a false feeling of shame and sometimes because it was hoped that a successful abortion or miscarriage might be managed. The increase of abortion of recent years was very serious; according to a recent article by Dr. Parish of St. Giles's hospital, the number had quadrupled in the last five years. Of 1000 patients admitted (half of whom were infected) 485 admitted instrumental interference, 111 admitted to the use of drugs, and 9 admitted that they had been to a criminal abortionist. He thought that it was not so much poverty as the desire of young couples not to restrict their amusements which was leading to this increase.

Of midwives there were two opposite types which did harm: (1) the kind who thought she knew everything and deprecated bringing in medical assistance even when necessary; and (2) the nervous kind who frightened her patient, sent for the doctor unnecessarily, and urged him to interfere. The problem of the doctor, however, presented the greatest difficulty. The training he received was lamentably inadequate at most schools, and the average man went into practice with no real practical experience. Many were extremely competent, but it was idle to deny that deaths were often directly due to lack of knowledge, errors of judgment, carelessness, hurry, or unwillingness to call in expert assistance. Though there was, and must be, an important place for general practitioners in any midwifery service it must be ensured that all who undertake the work are keen and competent. In spite of everything that so many authorities had said concerning droplet infection it was rare to find a doctor who would wear a mask. Every public health officer who had the task of investigating maternal deaths could quote not one but several cases in which a shocking ignorance or carelessness had apparently been displayed, and one of his councillors had actually proposed that a coroner's inquest should be held on every maternal death. Such a procedure, Dr. Topping thought, would do a great deal of good, but would lead to more trouble than was justified. The consultant, also, might share the responsibility for failure. Some were too prone to interfere unnecessarily; they felt that they had not justified their existence unless they displayed some *tour de force*. Her eagain public knowledge of the facts would be useful, for it would prevent women from thinking that the consultant got his money for nothing if he adopted a policy of masterly inactivity. Many consultants had been remiss in not emphasising the part played by bad midwifery in the causation of maternal deaths.

Finally there were ways in which the voluntary hospital or local authority might fail in their duties. It was freely admitted that some municipal hospitals were not so good as others, but rare to hear any voluntary hospital referred to as anything less than a cross between, say, Guy's and the Edinburgh Royal. But any hospital must be at fault if it purported to deal with maternity cases and fell short of accepted standards. Among local authorities many fulfilled recommendations in the letter, but not in the spirit. Their hospitals, too, might be inadequate; their antenatal clinics might not offer the requisite comfort and privacy, and the experience and qualifications of the medical officer in charge might not command the respect of practitioners. There should be continuity between antenatal and in-patient departments; there should be a self-contained pyrexia unit; the consultant should be an accepted authority,

and practitioners should not be openly or tacitly discouraged from making full use of his services. The medical officer of health was gravely at fault if he did not do his utmost to get his committee to do more than the minimum, and was to be pitied whether blameworthy or not, if his relations with practitioners were not cordial.

DISCUSSION

Dr. E. H. T. NASH (Heston and Isleworth) inquired whether there had been any difference in unemployment over the period in question in Rochdale. He asked because of the remarkable effects of the giving of milk in the Rhondda Valley which were especially evident during a nine months' strike when the women were properly fed for the first time from voluntary sources.

Dr. DUNSTAN BREWER (Swindon) found that even in an area in which the rate was low many deaths were still preventable though, of course, there was an irreducible minimum. He quoted a case in which the urine and blood pressure had been examined at 9 A.M. and found to be normal and the woman was having an eclamptic fit at 4 P.M. As far as statistics were concerned Dr. Brewer thought that the only possible basis was the convention adopted in New South Wales under which every death in a woman between the ages of 15 and 45 is considered to be a maternal death unless proved to the contrary. A scrutiny of all such deaths resulted in the true maternal mortality-rate in his area being always double that returned by the Registrar-General; for example, an inquiry into the death of a young woman from "myocarditis" revealed that a post-mortem had demonstrated a knitting needle in the peritoneum. Such an inquiry was only possible, unfortunately, in the smaller boroughs. The age at primiparity was important as was shown by the recent Canadian report. Dr. Brewer doubted whether the increase in abortions was genuine; might it not be due merely to lessened concealment and increased hospitalisation? On the other hand, he was certain that the art of obstetrics had degenerated in recent years.

The CHAIRMAN (Dr. M'Gonigle) wondered whether a too liberal interpretation of the Central Midwives Board rules for sending for medical aid by midwives was leading to harm through interference in normal cases. In some cases there was undoubtedly dichotomy between midwives and doctors.

In reply, Dr. TOPPING said that the incidence of unemployment had not varied in Rochdale during the period under discussion: in any case it was not the poor mother who died. He too had been impressed by the results of the Rhondda milk experiment, but he understood that a propaganda campaign had been initiated at the same time. His main contention, he said, was that once the true facts were known public opinion would be so strong that improvements would follow in all branches of the service whatever the cost. Undoubtedly, in his opinion, the time had come to speak the truth and shame the devil. Let the blame go where it belonged: to a careless public, an inefficient midwife, an inept doctor, or a badly run health department.

KENT COUNTY OPHTHALMIC AND AURAL HOSPITAL. On Feb. 14th Lady Davis opened the new buildings at this hospital at Maidstone. The president, Sir Edmund Davis, and Mr. E. W. Meyerstein have promised to give £2000 towards the extensions, but there still remains a debt of £3000.

LIVERPOOL MEDICAL INSTITUTION

At a pathological meeting of this institution on Feb. 20th, with Dr. E. GILBERT BARK, vice-president, in the chair, a paper on

Bacteriological Aspects of Puerperal Sepsis

was read by Prof. HEDLEY WRIGHT. The term puerperal fever, he said, was not synonymous with puerperal sepsis in the narrower sense, for in a series of 125 cases of fever in the puerperium it was found that only 48 were due to infection of the genital tract. Of these only 14 were due to hæmolytic streptococci and 10 were attributed to anaerobic streptococci. The occurrence of fever in the puerperium called for full clinical and bacteriological examination of the patient. But severe sepsis was most commonly due to hæmolytic streptococci, although as Colebrook had shown a not inconsiderable proportion of cases was due to anaerobic streptococci. In hæmolytic streptococcal infections blood cultures were negative in some 74 per cent. of cases and where positive the numbers present were usually small (less than one organism per c.cm. to 1000 per c.cm.) according to Hare, and comparable with the numbers found in infective endocarditis and other bacteriæmias. The blood infection was, therefore, to be regarded as a minor feature in the disease. There was sufficient evidence to indicate that the hæmolytic streptococci which caused this condition were not derived from among the normal inhabitants of the genital tract. Where such organisms had been found in the vagina before delivery the puerperium had followed an uneventful course. This was because the normal inhabitants were serologically and biologically distinct from the strains which were pathogenic for man; these fell into one large group which could be subdivided into a large number of types. This particular group had been found almost exclusively in the respiratory tract of normal human beings, the fæces of patients suffering from an infection of the upper respiratory tract, and on the hands of some normal persons. That the respiratory tract was the main source of infection in the puerperium was therefore to be expected, and in 103 cases reported by various authors 99 had actually been traced to such a source, 79 to some person in attendance and 20 to the patient's own throat or nose. Specific treatment with the sera available appeared to be completely useless, and it was possible that this was in part due to the difficulty of obtaining a serum adapted to the particular infecting strain, though more probably to the fact that recovery from infections of this kind was largely influenced by incompletely recognised factors within the local focus of infection in the genital tract.

In the discussion which followed, Dr. H. H. MACWILLIAM said that in the acute and severe cases of puerperal septicæmia there was very little localisation of the infection. He regarded thrombosis in the veins as an important factor in limiting spread. In these acute cases the vessels in the placental site did not show the clotting found in this situation in patients who had died from some other cause. When thrombosis occurred in the iliac veins the prognosis was relatively favourable and it was likely that thrombosis was very much more common in the ovarian veins than is suspected. Antimicrobial serum was useless, but Dr. MacWilliam thought that under certain conditions antitoxic serum, probably by supplying complement, was one of the most effective

agents we possess. Until recently the experience at Walton Hospital, Liverpool, was that if a good growth of hæmolytic streptococci was obtained from the blood in a broth medium by simple technique the patient nearly always died. About two years ago treatment with human serum was adopted, and since then the recovery-rate had been quite high.

MIDLAND MEDICAL SOCIETY

At a meeting of this society held at Birmingham on Feb. 5th, with Prof. W. H. WYNN, the president, in the chair, a paper on

Diverticulitis of the Colon

was read by Prof. SEYMOUR BARLING. He thought the condition was due to weakness at certain points in the bowel between the longitudinal bands, associated with abnormal stresses in the large bowel. This weakness he attributed to previous inflammation. The term "prediverticular state" he considered a misnomer, for he had seen a patient in the so-called prediverticular phase, with four years' symptoms, in whom at laparotomy temporary diverticula could be seen whenever the bowel was in spasm. In such a case diverticula had already formed. Another patient had died of ulcerative colitis, the musculature being involved in inflammation from the mucous membrane; and though the X ray picture was that of the "prediverticular state" no diverticula were present post mortem. There was a type with fibrosis and narrowing of the bowel wall, apparently due to inflammation and fibrosis strengthening instead of weakening the muscle-fibres, the diverticula being apparently incidental in some cases. Diverticulosis—where fully developed diverticula were present—was slowly progressive, but the symptoms were of a minor character and seldom necessitated operation. Cases with secondary infection were the ones usually seen by the surgeon and represented the true diverticulitis; the patients were mostly over 60 and it was the result of slowly progressive changes which might be overlooked in the early stages. Initial pain might be slight or severe; a tender colon might be palpable in the left iliac fossa and occasionally severe hæmorrhage was a sign—it had occurred in 3 cases out of the speaker's series of 28. Obstruction was not uncommon and might occasionally be due to carcinoma superimposed on the diverticular disease. Prof. Barling had had 5 cases with carcinoma out of 28. Early cases required medical treatment and surgery was needed chiefly for obstruction, spreading sepsis, or fistula. The disease was not the surgical curiosity it was considered to be and had to be kept in mind when an abdominal condition presented itself.

Dr. T. L. HARDY asked if any useful purpose was served by the term "diverticulosis." It suggested an active morbid process associated with symptoms, but many authorities did not regard it as such. Diverticula were present in about 5 per cent. of patients over the age of forty, a figure obtained by Rankin and Brown at the Mayo Clinic from 24,620 radiological examinations of the colon and 1925 post-mortem examinations. Whether uncomplicated diverticula ever of themselves gave rise to symptoms was debatable, his own view being that the symptoms complained of at that stage were due to an associated disturbance of bowel function, accidental rather than incidental to the diverticula. Dr. Hardy's personal experience of diverticulitis was, he said, small, and

he had records of only 22 cases (16 men and 6 women) in the past six years. He agreed with Prof. Barling that diverticula were largely manifestations of wear and tear; they showed themselves usually in the degenerative or decreescent period of life, the average age in his series being 58. Of his 22 patients 14 were noted as being obese and flabby. He did not think it need be assumed that spasm played an important part in the formation of diverticula, or that sympathetic or parasympathetic and endocrine influences were necessarily responsible; for neither true colon spasm, a much more common disorder, nor the various forms of colitis led to the formation of diverticula. The dangerous potentialities of diverticula needed no emphasis. According to Rankin, in about 15 per cent. of cases they became inflamed and gave rise to symptoms, the remainder being discovered accidentally. By their shape and feeble musculature, retention of faecal material was encouraged, and the way to subsequent infection and diverticulitis laid open. The physician saw these cases for one or more groups of symptoms—disturbance in the normal routine of bowel movement, abdominal pain, local or regional colitis, or vague ill-health associated with fever, shivering, and leucocytosis. Treatment took the form of what was somewhat euphemistically called "colon hygiene," and was as necessary, as a protective measure, where diverticula have been discovered accidentally as it was in established diverticulitis. At first, and whenever acute symptoms were evident, a bland diet of cereals, milk, eggs, and fish was desirable, with a period of rest in bed. Later, a full, well-balanced diet might be planned, though some loss of weight should usually be aimed at. Roughage must be always avoided and soft vegetables should be passed through a sieve. The bowels needed scrupulously careful regulation to avoid extremes; soft, semi-formed stools should be aimed at, but any form of irritating aperient was absolutely contraindicated. Rectal irrigation, if carefully given through tube and funnel at a pressure of certainly not more than 18 in. and limited to one pint, was occasionally valuable, especially where there was acute pelvic inflammation. An occasional enema of warm olive oil up to 6 oz., given over-night and retained till the morning, might also be used as a routine once a week or at longer intervals. Belladonna and hyoscyamus were certainly valuable in relieving the spasm and pain associated with diverticulitis. The mode of life should be one of all-round moderation; exercise in the form of walking, golf, shooting, and riding was good. A system of general massage and graduated abdominal exercises such as were embodied in the term "abdominal culture" were useful. Abdominal massage, however, was an appalling blunder, and Dr. Hardy had seen it precipitate an attack of subacute obstruction. A well-fitting belt to maintain intra-abdominal pressure was desirable when there was much protrusion.

Dr. HAROLD BLACK said that of 432 patients examined by barium enema in 1934, 68 showed diverticula (36 men and 32 women). He thought that few of those with diverticula developed diverticulitis, and mentioned that 15 per cent. of cases with carcinoma of the colon showed diverticula. It must be remembered that radiological abnormalities were not necessarily the cause of the patient's symptoms; one patient had numerous diverticula but the symptoms were later shown to be due to a ureteral calculus. Dr. Black thought the inflammatory bowel wall changes might be a result of the diverticula rather

than their cause, and that a degenerative change in the musculature of the bowel was a precursor.

Dr. J. F. BRAILSFORD did not think that diverticulitis was a contributory factor in carcinoma coli. Any association of the two diseases was probably accidental.

The PRESIDENT asked whether the condition might not be a disease of civilisation. Was the colon undergoing atrophy? What were the possible causative dietetic factors? He did not believe that inflammation was the cause of diverticula, but held that irregular bowel contractions were possibly concerned. He had seen two cases of plumbism with diverticula present.

PATHOLOGICAL SOCIETY OF MANCHESTER

At a meeting of this society on Feb. 12th Prof. S. L. BAKER and Dr. J. CRIGHTON BRAMWELL read papers on the

Pathology of Heart Disease

Prof. BAKER pointed out that inflammatory lesions in the myocardium itself appear to play little part in the production of myocardial failure. Vascular lesions due to coronary obstruction, atheromatous or syphilitic, were the chief cause of gross myocardial lesions. The development of a collateral circulation by anastomoses between coronary branches and pericardial branches from extracardiac thoracic vessels could modify the effects of coronary occlusion, particularly if this occlusion was gradual. Cases of complete obliteration of both coronary orifices by syphilitic disease had been reported; here the heart was supplied for a time entirely by such collaterals. Most workers at the present time believed that angina pectoris was produced by anoxæmia of the myocardium; it was usually, though not always, associated with coronary narrowing.

Cases of cardiac failure with myocardial hypertrophy formed an important group; such failure often occurred apart from valvular lesions in persons

with hypertension. A proportion of such cases showed coronary athero-sclerosis, but there were many without coronary obstruction in which, apart from hypertrophy, the myocardium showed no appreciable pathological change. The cause of myocardial failure in such hearts was a matter for speculation. There seemed a probability that the vascular supply failed to keep pace with the greatly increased bulk of hard-worked muscular tissue. Karsner and his co-workers had shown that in cardiac hypertrophy there was no appreciable increase in the number of muscle-fibres but a great increase in the mean diameter of each fibre. Unless the number of capillaries per muscle-fibre was greatly increased such hypertrophied fibres would be inadequately supplied with blood. No one had as yet investigated the problem from this point of view.

Summing up the pathology of myocardial failure, it could be said that, excluding acute toxic effects, factors interfering with the blood-supply, and certain rare cases of lesions of the conducting system, there remained a large group of cases of myocardial failure without adequate pathological findings. Here one had to assume that there was functional damage from overwork and possibly a failure of the blood-supply to keep pace with the demands of the hypertrophied and heavily worked muscle-fibres.

Dr. CRIGHTON BRAMWELL, after reviewing the changes which had taken place in the outlook on cardiology during the past fifty years, suggested that patients complaining of cardiac symptoms might be classified in three groups: (1) those with heart disease, (2) those with neuro-circulatory asthenia, and (3) those in whom symptoms were attributable to an anxiety neurosis. The first group consisted of inflammatory, degenerative, and other lesions of the heart itself, while in the second group the cardiac manifestations were secondary to such conditions as focal sepsis or disease in other parts of the body. Heart disease, neuro-circulatory asthenia, and anxiety neurosis might all be present in the same patient; in fact it was rare to meet with a case of heart disease in which there was not some element of neurosis.

REVIEWS AND NOTICES OF BOOKS

Localized Rarefying Conditions of Bone

By E. S. J. KING, M.D., D.Sc., M.S. Melb., F.R.C.S. Eng., F.R.A.C.S., Honorary Surgeon to Out-patients, Melbourne Hospital; Stewart Lecturer in Pathology, University of Melbourne. London: Edward Arnold and Co. 1935. Pp. 400. 35s.

ONE of the most fascinating features of medicine is the appearance, waxing, and waning of certain morbid conditions as centres of interest and attention. The interest aroused by particular diseases or injuries varies enormously from one decade to another quite independently of their prevalence. At the moment anything labelled "osteochondritis" evokes a prompt response from orthopædic surgeons, and the issue of a complete guide book to this maze of conditions is therefore timely. The initial and greatest difficulty is one of nomenclature: the G.O.M. of the osteochondritides (though not the first to be described) has been christened no fewer than fifteen times, and it is to be hoped that the name selected by Mr. King, "osteochondritis of the upper epiphysis of the femur," will now be accepted as the official title, if only for the sake of simplicity.

In this work the author has brought together all that is known about the various forms of osteo-

chondritis and certain types of bone atrophy. His command of the vast literature on the subject is so complete that the reader must be on guard lest he should overlook the author's own useful contributions. There is hardly an epiphysis in the body that has not been the site of an osteochondritis, and Mr. King has been vigilant in collecting references to all the forms of it, however rare. Legg-Perthes' disease and Osgood-Schlatter's disease are not typically "rarefying conditions of bone" and have little relation, as the author shows (p. 291), with Kummell's disease and its allies which are. All the same, a most useful service has been rendered in bringing together both groups of these puzzling conditions, and this book will almost certainly be a standard work of reference for many years to come. The first section deals with bone as a tissue, radiographic appearances, and certain anatomical features; the second describes every known form of osteochondritis. It is exasperating that, despite the efforts of Mr. King to lay before us all that is known, we are still very much in the dark about the aetiology and pathology of this type of bone disease. Good functional recovery so frequently follows conservative treatment that conscientious surgeons have had little opportunity of obtaining pathological material, and experimental

work has, for the most part, given little help. Various forms of bone atrophy, in which trauma plays a definite part, are described in Section III., and here again the exact causation is a matter for speculation. An excellent account of osteochondritis dissecans completes this work for which (apart from an X ray reproduced upside down on p. 287) we having nothing but praise.

The title of the book is not of the author's choosing; it was the subject set for the Jacksonian Prize of the R.C.S. for 1933, which distinction Mr. King won.

Bacteriology of Typhoid,

Salmonella, and Dysentery Infections and Carrier States. By LEON C. HAVENS, M.D., Director of Laboratories, Alabama Department of Public Health. New York: The Commonwealth Fund; London: Humphrey Milford, Oxford University Press. 1935. Pp. 158. 7s. 6d.

Now that the enteric fevers have become an intermittent rather than a continuous problem in this country a book by an enthusiastic worker with long experience of an endemic zone is particularly valuable. The late Dr. L. C. Havens was director of laboratories to the Alabama Department of Health, and in this little book he has given us the fruits of his experience in a clear and attractive form. The manual is essentially practical, but certain theoretical matters such as the different antigens of the typhoid-salmonella group are simply and adequately discussed. Stress is laid on the fallacious nature of a purely serological diagnosis of the enteric infections. The author points out that it should be possible to isolate the causative organism in a large percentage of cases, and he devotes a good deal of attention to the methods by which this can be done. The description of salmonella infections is apposite, and the subject has been shorn of the complexities with which it is usually presented in English bacteriological literature. A list of references giving in full the titles of papers is supplied at the end of each chapter and adds to the usefulness of an excellent little monograph.

An Index of Treatment

Eleventh edition. By Various Authors. Edited by ROBERT HUTCHISON, M.D., LL.D., F.R.C.P., Consulting Physician, London Hospital. Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall Ltd. 1936. Pp. 1020. 42s.

THE eleventh edition of this classic work, which begins with the editor's admirably succinct remarks on the principles of therapeutics, includes many subjects not dealt with in previous editions. For example, articles are supplied by the editor on agranulocytosis and its treatment by pentnucleotide, by Prof. A. W. M. Ellis on alkalosis, and by Dr. G. W. Bray on the complex problem of allergic disease. Dr. Donald Hunter writes on idiopathic steatorrhœa and tetany in the adult and the various techniques of cisternal puncture and its therapeutic possibilities are described by Dr. W. M. Feldman. Two other important new articles are by Dr. C. Newman on the functional disorders of the gall-bladder and by Dr. R. Lightwood on the anæmias of childhood. Many other sections have been revised or rewritten in the light of recent knowledge, but it is gratifying to see that those of Mr. James Sherren, a former editor, have been substantially retained. The surgical,

X ray, and glandular therapy of acromegaly are discussed by Dr. H. Gardiner-Hill. Prof. L. J. Witts deals with the treatment of the anæmias and Dr. S. Levy Simpson with that of Addison's disease by cortin injections. The section on the ear has been rewritten by Mr. L. Graham Brown, and Mr. Eardley Holland writes on calcium gluconate in the modern treatment of eclampsia. The treatment of acute nephritis by orange juice, of hypertensive encephalopathy by venesection and lumbar puncture, and of the various types of renal œdema are clearly expounded in Prof. Ellis's contribution on nephritis. There are nine articles by Mr. Victor Dix on various genito-urinary conditions and Dr. Levy Simpson describes the treatment of Raynaud's disease by calcium, parathyroid, thyroid, œstrin, and, if necessary, ganglionectomy. The potentialities of superficial and deep X ray therapy are summarised by Dr. J. F. Carter-Braine and the indications for treatment by Sanoecrysin, artificial pneumothorax, phrenic paralysis, and thoracoplasty are described in Dr. L. S. T. Burrell's masterly article on pulmonary tuberculosis.

It is no exaggeration to say that this book is a necessity to all who are seriously concerned with therapeutics, and the practitioner, temporarily depressed by lack of therapeutic success, will find herein much to cheer and inspire him to further effort.

Thorpe's Dictionary of Applied Chemistry

Supplement to Vol. III. By JOCELYN FIELD THORPE, C.B.E., D.Sc., F.R.S., F.I.C., Professor of Organic Chemistry and Director of Organic Laboratories, Imperial College of Science and Technology; and M. A. WHITELEY, O.B.E., D.Sc., F.I.C., formerly Assistant Professor of Organic Chemistry at the College. London: Longmans Green and Co., Ltd. 1936. Pp. 166. 21s.

IN the course of their preparation of the first two volumes of the supplement to Sir Edward Thorpe's classic work, the editors realised that within the past decade so many new technical terms have been coined that even the expert may find it difficult to understand expressions used outside his own branch of chemistry. To meet this difficulty they have now issued, together with the index to the supplement, a glossary of the terms used in it and of some other words and phrases which are in vogue in laboratory and factory. In completing the supplement they have thus provided us also with a compact independent work of reference whose value is enhanced by its pleasing and legible type.

Chronic Streptococcal Toxæmia and Rheumatism

By J. D. HINDLEY-SMITH, M.A. Camb., M.R.C.S., L.R.C.P. London: H. K. Lewis and Co., Ltd. 1935. Pp. 275. 7s. 6d.

THE streptococcus is cast for the part of villain in this book and is held responsible by the author for an unpleasant condition which is called chronic streptococcal toxæmia. This condition which, he believes, may begin in childhood, is gradual in its progress and in its method of establishing itself, but may ultimately condemn those who suffer from it to a life of semi-invalidism. Chapter I. opens well. Most readers will be in sympathy with the author's claim that the clearly defined and labelled diseases which progress according to a definite programme, and are described in text-books, account for a minority of

the ills of mankind; whereas most of the diseases met with in general practice are neither well defined nor really understood, and much good could be done by collecting and sorting out clinical observations, particularly those made by experienced practitioners. When, however, Dr. Hindley-Smith proceeds to such statements as "the vast majority of cases suffering from chronic toxæmia are suffering from acid toxæmia, and the causes giving rise to acid toxæmia are legion," most of us will part company with him. This conception of acidity and acid toxæmia in relation to the rheumatic diseases has surely been discarded. In their book on chronic arthritis reviewed in *THE LANCET* (1935, i., 618) Pemberton and Osgood say wisely: "One frequently hears from patients the statement that his doctor has told him he was 'too acid,' to counteract which condition he was given alkali in some form. The time is past when medical men can afford to tolerate such vagaries which have neither clinical nor scientific justification." Dr. Hindley-Smith's suggestion that the victim of prolonged anaesthesia will experience the feeling of general poisoning throughout the system long after consciousness has returned is also misleading. The alarming picture drawn of the sufferer from chronic streptococcal toxæmia is surely exaggerated. So the book goes on, a mixture of shrewd observation and comment interlarded with loose statements for which there is no scientific support. All we can say of it in praise is that the section on treatment should help the doctor whose patients are clamouring for "something to be done."

The Anti-Drug Campaign

An Experiment in International Control. By S. H. BAILEY, Senior Lecturer in International Relations, London School of Economics and Political Science. London: P. S. King and Son, Ltd. 1936. Pp. 264. 12s.

Mr. Bailey has put together a useful and timely account of the tangled story of the efforts to secure international control of the traffic in dangerous drugs, from the Shanghai Commission of 1909 to the Convention on Limitation of Manufacture of 1931. In an appendix extending over a hundred pages there are set out the provisions of the Hague Convention of 1912, the Geneva Agreement and Convention of 1925, the Bangkok Agreement and the Limitation Convention of 1931. The evolution of international control of the traffic in opium, morphine, heroin, and cocaine is described, but it is recognised that side by side with the licit demand, clandestine opium smokers and drug addicts create an illicit demand of unknown volume. There is thus encouraged the harvesting of quantities of the raw materials which bear no relation even to the most liberal estimates of legitimate requirements. The author regards the Hague Opium Convention of 1912 as an event of the highest significance, being the initiation of a multilateral international instrument for combating a world-wide evil. In view of the persistence of legalised opium-smoking in the Far East, he naively remarks that it is difficult to resist the conclusion that European Powers have taken a lighter view of their responsibilities to the peoples subject to their administration in Eastern Asia than to their nationals in their home countries. The improvements effected under the Geneva Convention of 1925 in the control of international traffic in drugs and the creation of the Permanent Central

Opium Board are set off against the failure to limit the production of raw opium and coca leaves to legitimate requirements, a step contemplated by the League of Nations and demanded by the United States delegation. That more remained to be done was shown by the Secretariat of the League when it reported that between 1925-29 more than 100 tons of habit-forming drugs derived from morphine passed into illicit traffic. The disclosures in the "Naarden case," where a licensed Dutch factory was found to have exported over 2000 kg. of heroin and 860 kg. of morphine to the Far East in a little more than one year shocked a good many complacent people, as did also the revelation by Russell Pasha of the havoc wrought in Egypt by uncontrolled drug factories in Istanbul. There followed in 1931 the conference and convention on the limitation of manufacture and distribution of narcotic drugs which did not, however, extend to the production of raw opium, coca leaves, prepared opium, or Indian hemp. The attempt to establish a quota system for allocating to each nation a proportion of the world requirements of the drugs in question having been abandoned, the supervisory body, set up by the 1931 Convention, has achieved considerable success in securing both national and international control of the traffic in narcotic drugs. Much remains to be done, notably in the restriction of production of raw opium and coca leaves, but the author is justified in ending his lucid account of the anti-drug campaign with the conclusion that from the tangle of mixed motives which divide the erratic course of governmental policy a constructive purpose has emerged and seems destined to prevail.

A Short Ante- and Post-Natal Handbook

By R. KELSON FORD, M.D., M.M.S.A., St. Olave's Hospital, Rotherhithe. London: Humphrey Milford, Oxford University Press. 1935. Pp. 141. 6s.

OUR medical schools and hospitals have something to learn, especially on antenatal supervision, from the clinics and hospitals under local health authorities. The public antenatal clinics are primarily a system of constructive hygiene, whereas those of the teaching and voluntary hospitals or departments remain too exclusively a means of picking out doubtful or abnormal cases for special observation and management. Hence we look for greater prominence of the hygienic, social, and educational aspects in a manual by one in the service of a local authority than in similar books from the teaching schools. Dr. Kelson Ford's introductory chapter is excellent in that these aspects are placed in the foreground of the picture. The reason for antenatal supervision is much more than the detection of pelvic deformity and albuminuria. Stress is laid on the necessity for the careful study of the individual patient, her instruction in hygiene for herself and the infant after birth; the advice to the doctor to make an effort to assess the attitude of mind in which pregnancy is regarded is much needed. Although Dr. Ford has laid down the principles clearly and concisely, he has not been successful in weaving them into the texture of practice with the same clarity and emphasis. The "Author's Note," which occupies the place and office of a preface, does not say more of the object he had in mind than that "no attempt has been made at being exhaustive, a helpful suggestiveness being the aim." This aim has undoubtedly been fulfilled, for he has produced a useful and stimulating

guide to ante- and post-natal care that will appeal to a large class of family practitioners, from whom much is now expected in the way of such service.

Our chief regret is that Dr. Ford has thought fit "to collect information not always readily accessible" into a small handbook, which is not the place for out of the way information. The outstanding instance is an encyclopædic classification of monstrosities and malformations, happily relegated to the appendix, where it takes up more space than any of the other and more suitable matters considered therein. Although he apologises for including much that is elementary, these portions modified in the light of personal experience form the most valuable characteristic of his book, and would best bear expansion. Further detail in such matters as physical exercises for pregnant and lying-in women or in the technique of assessing the patient's mental reaction to pregnancy would have been a welcome addition and most helpful. We trust, also, that other authors in the service of public authorities will not feel constrained to include such a disclaimer as "the London County Council is in no way responsible for any opinion or matter presented." It is a terrifying suggestion that city fathers and county councillors might assume some form of censorship over medical thought and practice, even if only among those in their own service.

Urology in Women

Second edition. By E. CATHERINE LEWIS, M.S. Lond., F.R.C.S. Eng., Surgeon to the Royal Free Hospital; Surgeon and Urologist to the South London Hospital for Women. London: Baillière, Tindall and Cox. 1936. Pp. 100. 6s.

MINOR urinary troubles in women are particularly liable to be missed or to receive inadequate treatment. This is specially true of lesions of the urethra and bladder, organs that lie on the boundary of gynæcological practice and in which the gynæcologist as a rule is not keenly interested. Minor lesions of the urethra are often missed, and the examination of this structure even by the urologist himself is often perfunctory. It was therefore the sections in the previous edition of this book which dealt with such conditions as urethral prolapse, urethritis, stricture, displacements of the bladder, and vesical neck obstruction that proved especially valuable. In this edition sections on nephroptosis and on changes in the ureters during menstruation and pregnancy have been added.

The book should be studied not only by practitioners, but also by gynæcologists and urologists.

Glandular Physiology and Therapy

A Symposium prepared under the auspices of the Council on Pharmacy and Chemistry of the American Medical Association. Chicago: American Medical Association. 1935. Pp. 528. \$2.50.

DURING 1935 a series of excellent articles on glandular physiology and therapy appeared in the *Journal of the American Medical Association*, prepared under the auspices of the council on pharmacy and chemistry of that Association. These articles have now been collected together to form a symposium of a comprehensive nature. The last publication of the kind appeared originally in 1925 and in revised form appeared two years later. Since then, however, remarkable advances have taken place in endocrinology. Each chapter is an authoritative discussion

by a well-recognised worker. Thus, Evans writes upon the clinical manifestations of dysfunctions of the anterior pituitary and the growth hormone; Collip deals with the inter-relationship among urinary, pituitary, and placental gonadotropic factors; Allen discusses menstruation and the physiology of oestrogenic principles; and Marine writes on goitre; other chapters are supplied by Best, Joslin, Aub, Aschheim, Fishbein, Novak, and Zondek.

Clinicians and physiologists alike will appreciate this symposium.

THE RED CROSS AS SANCTUARY

A MEMORANDUM on observance of the Red Cross in warfare has been prepared for presentation to the Italian Ambassador by members of the medical profession. Its terms are as follows:—

We, who sign this memorandum as members of the medical profession, wish in this way to express our profound uneasiness at the news of certain incidents that have occurred in the course of the present war between Italy and Abyssinia. It is reported that on six occasions units clearly displaying the Red Cross have been bombed from the air by the Italian forces; and it seems to be established that on some of these occasions, at least, the action was premeditated.

The members of our profession have never assumed or claimed that they, any more than other citizens, should be held immune from the risks of war. The character of their work calls for men and women of normal courage; and the casualties among doctors attached to fighting units during the European War are themselves proof that this protest is no mere personal one. Our sense of indignation lies far deeper. In wartime, the wounded and those who attend them have for long past been considered as in a sanctuary when beneath the Red Cross. Amongst civilised peoples the Red Cross has been looked upon as an assurance that, above the shifting tides of national strife, commercial rivalry and war, there still lives the true bond of common humanity. If this permanent bond, symbolised by the respect customarily paid to the Red Cross, is also to be destroyed, then mankind takes a further step backwards towards the chaos of barbarism.

The fact that our profession usually does its work unostentatiously makes it all the more becoming that we should from time to time express ourselves most emphatically on a matter that so gravely touches our professional conscience. It is necessary that all who follow the vocation of medicine should insist that the symbol of the Red Cross in war be held absolutely sacrosanct.

In order that the protest may be as effective as possible, all those who wish to associate themselves with it are requested to communicate as soon as possible with Dr. T. O. Garland, 23, South Hill Park-gardens, London, N.W.3, so that their names may be added to the list of supporters.

The preliminary list of supporters, we are informed, includes:—

Rt. Hon. Christopher Addison, P.C.
 Dr. G. F. Barham.
 Dr. F. G. Bushnell.
 Dr. D. Elizabeth Bunbury.
 Dr. William Barr.
 Dr. E. Vipont Brown.
 Dr. H. Crichton Miller.
 Prof. Millais Culpin.
 Dr. W. R. Dunstan.
 Mr. P. G. Doyne.
 Prof. W. M. Frazer.
 Dr. David Forsyth.
 Prof. Major Greenwood.
 Dr. Helen Gillespie.
 Mr. Somerville Hastings.
 Dr. P. D'Arcy Hart.
 Mr. Cecil Joll.

Dr. H. Joules.
 Dr. Peter Kerley.
 Dr. John D. Kershaw.
 Dr. W. Howlett Kelleher.
 Dr. R. D. Lawrence.
 Dr. R. A. Lyster.
 Mr. C. Lambriaudi.
 Mr. Philip H. Mitchiner.
 Prof. J. R. Marrack.
 Dr. S. V. Pearson.
 Dr. Alfred Salter.
 Dr. D. R. Sagar.
 Dr. M. W. Walmesley.
 Prof. E. J. Wayne.
 Dr. Robert F. Collis.
 Dr. Stella Churchill.
 Dr. Doris Odium.

THE LANCET

LONDON: SATURDAY, MARCH 7, 1936

MESCALINE IN PSYCHIATRIC RESEARCH

THE field for controlled experimental research in psychiatry is still so small that it demands intensive cultivation. One of the few methods available is a pharmacological one—i.e., the use of intoxicating drugs. The psychosis thus produced can be studied with a much closer regard to experimental requirements than is possible with the mental disorders in general, dependent as they are on a variety of causes which the investigator can seldom influence in any predictable direction. Foremost, though not unique, among the intoxicants that may be used for research along such lines is mescaline. Now available as a synthetic drug, its ritual use on the American continent stretches back to the time before the Spanish Conquest. Fascinating as are the ethnological associations of the mescal plant, it is as a source of beatific visions that it has become generally and somewhat romantically known in Western Europe. The visions consist of fantastic forms and colours constantly changing but always bright. Dr. MACDONALD CRITCHLEY, who made some subjective experiments in 1930, described¹—

“a meadow with buttercups and daisies; now it is changing into a stereotyped park, with a bandstand and with chairs, each one of which is whizzing rapidly round on its own axis. Butterflies are coming in from all sides; the bandstand has disappeared. The butterflies all collect into the centre and arrange themselves into a circular, brightly coloured flower-bed, rotating rapidly in a clockwise direction, in a most wonderful manner . . . now a huge field of primroses . . . a complicated pattern like Hampton Court maze, brightly coloured with objects moving quickly in a snake-like, sinuous fashion along the apparently endless pathways of the maze.”

All who have enjoyed the contemplation of just such sights and sequences in a Silly Symphony will appreciate what a state of rapture they may induce. The range of the abnormal phenomena to which mescaline gives rise is, however, wider and more important from the investigator's point of view than the visual disturbances alone. The independent phenomena in other sensory territories, the synæsthesiæ, the alteration in bodily feeling, the disorder experienced in space and time-judgments, the effects on mood and thought, the depersonalisation and the power of detached observation of oneself are among varied manifestations which have been closely studied by psychiatrists. WEIR MITCHELL and HAVELOCK ELLIS drew attention to them in the last century; since the war some workers at Heidelberg, ROUHIER in France and others have examined the matter thoroughly.

At the meeting of the Royal Medico-Psychological Association on Feb. 26th Dr. ERICH GUTTMANN described investigations to which he had contributed before he came to England, and gave an account of the further mescaline research which he and others are carrying out at the Maudsley Hospital. By means of the Rohrschach test, administered to the same persons before and after intoxication, he had observed the changes in those responses which are regarded as indicative of the psychological type and personality of the subject. By this means the contribution of the individual to the psychosis—a question of the first importance for psychopathology—can be studied, as well as the effect of specific noxæ on psychic structure; the rôle of perception in the total personality also enters into the field of experiment. On the same subjects (normal volunteers) Dr. W. H. HUBERT and Dr. AUBREY LEWIS studied by a special optical technique the changes in Gestalt-formation produced by the drug; striking variations were found, again bearing on the importance of the perceptual side of personality. Comparative investigations, using the same technique, but without mescaline, on schizophrenic patients and others with depersonalisation were made, and provide an instance of the valuable approach which mescaline affords to the study of mental illness, especially where, as in schizophrenia, the investigator cannot otherwise than by mescaline himself gain any subjective experience of the incommunicable phenomena. Dr. GUTTMANN has, moreover, in conjunction with Dr. W. S. MACLAY, attempted to make therapeutic use of the drug. The known effects on sensory function led them to expect that the symptom of depersonalisation with feeling of unreality might be so modified or abolished temporarily by small doses of mescaline that the patient would be more accessible, after this relief, to psychotherapy. The results, so far as feelings of external reality were concerned, conformed to expectation (though not in all cases) and the change extended beyond the period of intoxication. Incidentally Dr. GUTTMANN and Dr. MACLAY hold that to give mescaline continuously to any patient would not be justifiable while we know so little about the dangers of chronic mescaline intoxication.

The information available about the oxidative and enzymic activities of the brain during mescaline intoxication has so far indicated only a common mode of action of narcotics and throws no light on the specific effects of the drug. Dr. P. K. McCOWAN stressed the importance of further research into these activities. Dr. GUTTMANN referred to the physical changes which appear during intoxication and to their metabolic significance. It is noteworthy that in 1932 an observer reported that in hashish intoxication the output of salt and water is increased, without any concomitant hydræmia; it is not known whether any corresponding change is associated with mescaline. It is an attractive speculation that there may be links between mescaline and some of the end-products of protein metabolism—e.g., tyrosine—

¹ See THE LANCET, 1930, II., 863.

to which it is chemically allied; an attempt to discover whether some perversions of normal metabolism result in the production of a toxic substance closely akin to mescaline pharmacologically as well as chemically might be fruitful. Admittedly no substance closely related chemically to mescaline has as yet been found capable of giving rise to its remarkable effects; whether further research be metabolic or psychological, the value of a pharmacological approach to the problems of psychiatry can hardly be doubted.

HEAT REGULATION AND FEVER

IN his Arris and Gale lectures just delivered before the Royal College of Surgeons of England Dr. JOHN BEATTIE reviewed various aspects of the heat-regulating mechanism of the body, and expressed his belief that this mechanism is much more complicated than has hitherto been realised. The notion that heat regulation is dominated completely by a single centre is in his opinion misleading, and he was able to show that sections at different levels of the central nervous system produce widely different effects. The argument in favour of a single centre has been founded largely on experimental demonstration that section of the cervical cord completely abolishes the heat-regulating mechanism so that the animals become poikilothermic. To support this conception there is also the older evidence from heat piqure, and the more recent observations that local heating of the hypothalamus is followed by lowering of the body temperature, and local cooling by a rise in the body temperature. To the contrary, however, we have abundant clinical evidence, beginning with a case recorded by BRODIE in 1837, that in man complete destruction of the cervical cord is not always followed by a loss of heat regulation and that even fever has been observed in such patients. A few isolated observations on animals are also on record such as those of GOLTZ and EWALD in 1896, and the more recent ones of POPOFF,¹ where heat regulation was maintained after removal of the spinal cord from the cervical region downward with subsequent cutting of the vagus and sympathetic in the neck. In order to determine the reason for this contradiction, THAUER,² working in BETHE's laboratory, has lately carried out an extensive experimental reinvestigation of the effects of section of the cervical cord on a large number of rabbits, guinea-pigs, and rats. Suspecting that the discrepancies might be due to immediate shock effects masking the true results of the operation, he endeavoured to improve the operative technique and post-operative treatment. By keeping the animals immediately after the operation in a thermostat at 28°-30° C. and by careful attention to their feeding, he succeeded in keeping a number of animals alive for several weeks, and three rabbits for two months after the operation. In all these animals the heat-regulating mechanism was almost completely restored, although during the first few

days after the operation it was severely impaired. When once the heat regulation had been restored subsequent cutting of the cervical sympathetic and of the vagi, and even subsequent partial removal of the thoracic spinal cord, failed to impair it. THAUER's results agree, therefore, with those of POPOFF in showing that in warm-blooded animals after complete exclusion of the central nervous system the heat regulation of the body can be efficiently maintained by a peripheral mechanism. The nature of this peripheral mechanism has been indicated by the work of CRAMER, who showed in his well-known monograph³ that in addition to the nervous mechanism for heat regulation there is a humoral mechanism with which the thyroid and adrenal glands are particularly concerned. Since most of the factors concerned in heat regulation are controlled by the sympathetic nervous system, they can be brought into play either by nervous or by humoral stimulation. Thus fever can be produced experimentally by functional hyperactivity of the thyroid or adrenal glands, and THAUER has shown that his animals deprived of their central nervous control still respond to infections or to the injection of pyrogenic substances by fever.

The experiments of POPOFF and of THAUER must, of course, not be interpreted as denying the existence of a nervous mechanism for heat regulation or of a central coördination of such a mechanism. Such a conclusion would be as crude and as misleading as the reverse one that the thyroid or adrenal glands have no part in the processes of heat regulation because these processes can still be efficiently maintained after removal of one or other of these organs. We are being led to a belief that there are two mechanisms for heat regulation, one central and the other peripheral, a conception in keeping with modern physiological trends in other bodily functions. In the control of water metabolism, the control of equilibrium, and in sensory discrimination there are parallels for the overlaying of a crude peripheral type of regulation by a more delicate centralised one. On our present knowledge of heat regulation it must be supposed that the intracranial apparatus is not essential to an adequate working, but rather by allowing an interplay between the different peripheral factors serves to increase their efficiency, especially under pathological conditions.

The conception of a single centre dominating heat regulation has tended to sterilise progress, and a study of LAKIN's Lettsomian lectures⁴ reveals how scarce investigations on the phenomenon of fever—one of the most frequent and important clinical symptoms—are in the recent physiological, pathological, and clinical literature. It is easy to understand why this should be so. On the unitary conception fever is explained as being due to some action on the heat-regulating centre in the brain which is likened to a thermostat, and in fever is

⁴ Lakin, C. E.: *Disturbances of the Body Temperature*, THE LANCET, 1934, ii., 467.

supposed to be "set" at a higher temperature. But from what has been said above, and from what Dr. BEATTIE said in his lectures, it is clear that if there is a heat-sensitive zone in the brain there must also be other thermo-regulators outside it—represented perhaps by the sympathetic ganglia. Formerly it was assumed that the fever of infectious diseases is due to the action of bacterial toxins on cerebral centres; but it has now been shown that many bacterial toxins circulating in the blood cannot pass the blood-brain barrier,⁵ which is additional evidence that their effects must be on the periphery. Moreover, it is now known that some pathological conditions of the thyroid or adrenal glands are associated with a pyrexia indistinguishable from that of an acute infection, for which in the past they have been frequently mistaken. This recent work on the decentralisation of sympathetic functions may well open up new fields for clinical applications in the pathogenesis and treatment of infectious diseases and of other pyrexial conditions whose origin is at present only surmised.

ACUTE NICOTINE POISONING

LAST week Dr. L. P. LOCKHART drew attention in our columns to a case in which a father, in order to make his 14-year-old boy give up smoking, adopted the heroic measure of forcing him to eat a cigarette. Curiously enough, "the father's action appears to have received the approval of the court," and Dr. LOCKHART rightly raised a protest. It is salutary to remember that poisoning by small doses of concentrated nicotine is usually rapidly fatal, and that present-day remedies are often of no avail. Admittedly recorded fatal cases are few, but as ESSER and KÜHN⁶ point out their incidence has increased recently. In many of them nicotine is taken with suicidal intent, but poisoning has also occurred in factories where concentrated nicotine is handled and in tobacco factories. Non-fatal poisoning is seen among cigar and cigarette makers who inhale tobacco dust and among workers who handle concentrated nicotine and may have their skin splashed with it. The main symptoms are ocular troubles, such as partial blindness with limitation of the fields of colour vision, functional heart disease, and nervous disorders. ALICE HAMILTON⁷ says that new workers in factories often suffer from the same disorders as the inexperienced smoker—headache, palpitation of the heart, rapid irregular pulse, nausea, and vomiting. She regards the evidence for the existence of chronic nicotine poisoning as scanty because sooner or later an immunity to the drug is established. However this may be, it is certain that more cases of acute nicotine poisoning are occurring at the present time, and it is therefore important that an adequate method of treating it should be found.

FRANKE and THOMAS,⁸ who have just reviewed the subject, say that apart from the usual procedures for removing any unabsorbed poison and the administration of stimulants, they have been unable to find any description of a rational treatment for nicotine poisoning. The condition is usually considered to be hopeless: "this pessimistic attitude is apparently due to the belief that the drug causes generalized paralysis of the central nervous system, based on the fact that complete muscular paralysis, loss of reflexes and paralysis of respiration (and finally of circulation) follow its absorption in sufficiently large doses." Their own experiments on dogs, however, lead them to think that death from nicotine poisoning is caused by peripheral, rather than central, paralysis of the respiratory muscles. Further, they show that nicotine does no evident irreparable damage to any of the structures on which it acts, and that the administration of very large doses is not incompatible with reasonably prompt and apparently complete recovery when appropriate treatment is started in time. FRANKE and THOMAS come to the important conclusion that nicotine poisoning should be regarded as a temporary respiratory emergency comparable with drowning or electric shock, and should be treated in the same way as these two conditions, especially by artificial respiration. They tried various means of treatment and resuscitation on 52 dogs poisoned with nicotine and found that if artificial respiration was applied before the circulation had failed, and maintained until the muscular paralysis had disappeared, each animal made a complete recovery. When treatment was started after failure of the circulation, artificial respiration by itself was usually not sufficient; but that if the animals were given in addition intracardiac injections of epinephrine (adrenaline) and indirect cardiac massage about half of them recovered. The important thing about these experiments is that they demonstrate that the circulatory failure which follows fatal doses of nicotine in dogs is not necessarily permanent, but that if the heart can be restarted and artificial respiration maintained prompt recovery is usual.

If FRANKE and THOMAS's conclusions are valid and can be applied to man they should lead to an increase in the proportion of recoveries from acute nicotine poisoning; for these authors have been able to find only 3 recorded in which artificial respiration has been used in its treatment. MOORE and ROWE⁹ in 1897 pointed out that the observed effects of nicotine could all be as readily ascribed to a curare-like action of the drug as to a central paralysis; and GOLD and BROWN¹⁰ have recently presented strong evidence that in animals it causes a peripheral rather than a central paralysis of respiration. It appears therefore that artificial respiration is the basis of a rational treatment for acute nicotine poisoning.

PENAL CASES IN CAMERA BEFORE THE G.M.C.

THE prolonged hearings in camera recently of penal cases coming under the consideration of the General Medical Council may have been taken as evidence of a tendency on the part of the Council to conduct more of such proceedings without a public audience. But as a matter of fact the situation is not so, and the circumstances at the last session of the Council were quite fortuitous. It is inadvisable, however, that an impression should remain that the G.M.C. is embarking upon a new policy of secrecy.

The penal jurisdiction of the Council rests substantially on these three words in the Medical Acts—"after due inquiry." The Acts provide that, in cases other than those based on convictions of felony or misdemeanour, the Council, if it finds "after due inquiry" that the practitioner has been guilty of infamous conduct in a professional respect, may direct the Registrar to erase the practitioner's name from the Register. We need not now refer to the unfortunate phraseology which has led to frequent protest. The word infamous has a technical legal meaning explained by the judges as disgraceful or dishonourable in a qualified professional man acting as such; but the scope of the words "after due inquiry" has never been exactly defined. When an action of the Council has been the subject of legal inquiry the Law Courts have taken the view that the Council can be trusted to manage its own business properly and competently, and they will not interfere unless the complainant can show a substantial impropriety of procedure. The Council's procedure is governed by its standing orders, which probably lack the statutory force comparable with the by-laws of some other semi-public bodies. But the orders give the Council wide powers of discretion in deciding which, if any, parts of the case shall be heard in camera. The Council is obliged only to open the case, that is to have the charge read, and to give the judgment in public, and variation from procedure in courts of law is conspicuous. All courts are open to the public unless in the opinion of the judge it would be clearly impossible to do justice at a public hearing, and the judge's discretion here is limited. The class of cases in which courts have restricted publicity are those in which the subject matter of the action has been some secret process; those where a witness must give evidence of such a distressing kind that he would not bring his complaint at all if he knew that the hearing would be public; and thirdly, where disorder is held reasonably certain to break out in court during the hearing. The General Medical Council is only concerned with cases of the second class, and has interpreted its discretion widely. The criterion applied by the Council it would seem is not whether justice can be done at all in public but whether it can be better done in private, while taking note of the fact that in the interests of decency some cases had better be heard in camera. Anyone who has followed the penal procedure of the Council at all closely will know

how few are the cases that fall under the latter heading; and it must be remembered that medical men summoned to appear before the Council may be willing, and naturally would be when innocent, to have the procedure a perfectly public one, the decision to hold the inquiry in camera being that of the Council.

When public attention is arrested by penal cases before the G.M.C., there is a natural surprise that the verdict of the Council, though it may deprive a professional man of his livelihood, is subject to no appeal. The victim's friends, thinking him innocent, attack the doctor's profession for an act of injustice which is final. This absence of appeal is due not to the caprice of the profession but to the will of Parliament as declared in the Medical Acts. From disciplinary decisions in other professions—dentists and solicitors, veterinary surgeons and architects—there is in each case an appeal to the High Court under the corresponding statute. The Medical Acts alone make no such provision. Consequently, as Lord Justice BOWEN observed, when "due inquiry" has been made by the G.M.C., "the jurisdiction of the domestic tribunal, which has been clothed by the Legislature with the duty of discipline in respect of a great profession, must be left untouched by courts of law." But the courts of law will intervene fast enough if the tribunal displays bias or transgresses the rules of what is rather vaguely called "natural justice" in its inquiry. In that event, it is safe to predict, amendment of the Medical Acts will follow.

ON Tuesday, March 24th, at 5 P.M., Sir Thomas Barlow will take the chair at the hundredth annual general meeting of the Royal Medical Benevolent Fund, which is being held at 11, Chandos-street, London, W.1.

THE appointment of Mr. Wilfred Trotter, F.R.S., to a chair of surgery in the University of London, tenable at University College Hospital medical school, is recorded in another page. No academic honour could enhance the reputation of one who has long been recognised not only as a master of his craft but as a scholar whose ripe philosophy pervades all his activities. But by consenting to sacrifice the leisure gained through retirement from private practice he confers additional distinction on the institution which he has already served for many years.

MR. GEORGE VERITY, who died at his home at Chesham Bois on Feb. 28th, was a truly practical friend to the cause of medicine. He was for close upon thirty years chairman of the governors of Charing Cross Hospital, and everyone concerned with the welfare and organisation of the great London hospitals knew of the work which he did at Charing Cross and admired the foresight and energy displayed. He accepted the responsibilities of chairmanship at a critical period in the history of the hospital which was suffering perhaps more acutely than any other of the metropolitan institutions from financial depression. The fine position in public and scientific esteem in which the hospital is now held was greatly due to Verity, for whom, in his labours, no ideal was too large to aim at and no detail was too small for attention. He has left a great name in the hospital world.

ANNOTATIONS

WEIGHT-LOSS AND POST-OPERATIVE MORTALITY IN GASTRIC SURGERY

POST-OPERATIVE pulmonary complications are notoriously more common after upper abdominal operations than after most other major surgical procedures, and the factors that determine them are still imperfectly understood. Among those factors is undoubtedly the patient's "resistance," both to infection in general and to operative shock—an imponderable factor, one would have said, a measure of which would be of great value were it feasible. H. O. Studley,¹ of Cleveland, has just suggested that it may be in some degree ponderable after all, and that literally. He took a series of 46 consecutive patients operated on for gastric and duodenal ulcer, excluding urgent laparotomies for perforation and acute hæmorrhage. There were 7 post-operative deaths (15 per cent.). These seemed to bear no relation to age, pre-existing cardiac or pulmonary disease, the position of the ulcer, the presence of pyloric stenosis, or the nature and technique of the operation. When he calculated, however, the amount of weight that the patients had lost before they came to operation, he found that 6 of the 7 deaths occurred among those who were 20 per cent. or more below their normal or highest known weight. This group contained 18 patients, with weight-losses ranging from 21 per cent. to 43 per cent. Five out of the 6 who died developed pulmonary infections, which may be supposed to have been the chief cause of death, although in 2 of them the wound ruptured as well. The sixth apparently died from wound rupture alone. In the other group of patients, numbering 28, who had lost only 3–19 per cent. of their maximal weight, 5 examples of pulmonary infection occurred but were not fatal, while the only death that did occur was due to ileus of mechanical origin.

On such scanty evidence the author's thesis cannot be accepted as a sound conclusion, but as a tentative suggestion it is worth considering. Thyroid surgeons have come to think that a rising weight in a patient with thyrotoxicosis augurs well for a smooth passage in thyroidectomy, and it may well be that slow changes in body-weight, not produced by disturbances in water balance, are a useful indication of the body's general metabolic well-being and of its "resistance." More observations are easily made, and are worth making. But if the thesis should come to be sustained, it is not necessarily to be used as an argument against what Studley calls "the policy of delay in advising surgical treatment of chronic peptic ulcer, . . . now generally followed." It rather points to the need for such pre-operative preparation of the patient as will restore some of his lost weight and strengthen his resistance; except in cases of obstruction, rest in bed and suitable feeding—in some cases perhaps duodenal or jejunal tube-feeding—will often achieve this end, and in the obstructed cases the same thing can be done by means of a preliminary jejunostomy made under local anæsthesia.

MEDICAL OPUSCULES

THE reading supplied in this interesting volume of "Opuscula Selecta" (issued by the *Nederlandsch Tijdschrift voor Geneeskunde*, Amsterdam) is of a varied sort. It is made up of letters interchanged between distinguished doctors of different nationalities

and sometimes between them and their patients, dealing with surgical and medical incidents that may be considered to have formed sign-posts in science. The dates range over the sixteenth, seventeenth, and eighteenth centuries. Dr. M. A. Van Andel points out in an interesting editorial preface that only by such letters could diffusion of medical information take place at a time when very few scientific books were printed and those only at great expense, while during the infancy of printing the suggestion of journalistic production could not have occurred to any mind. Undoubtedly the savants of this grand period in scientific activity exchanged many valuable contributions to knowledge in this manner, and the doctors as well as other leaders of thought were great letter-writers, their patients often being described in the most particular terms. It may be noted, here, that Guido Patin avers that there is as much difference between a doctor's dependence upon information from a distance about the condition of a patient as between Alexander the Great conducting a campaign personally and a king making war through his generals—the difference between conjecture and discovery. The letters throughout abound in theoretic commentaries which to some extent take the place of the clinical conferences of to-day. The authors include, among others, Vesalius, Van Beverwijck, Descartes, Boerhaave, Petrus Camper, and three communications from certain later surgeons are added, among them notes from Diderik Ort and Johan Ramaer to Prof. Tilanus describing cases of gastrotomy. The book is illustrated with pictures of many of these old masters, which are accompanied by biographical notes carefully dated. There is, alas, no index, thus adding to the difficulty of the reader, who will find the languages employed by the writers not necessarily familiar though the letters are furnished sometimes with Latin translations.

NARCOSIS IN ANIMALS AND MAN

THE danger of applying to human beings conclusions drawn solely from experiences with animals was one of the morals drawn by Prof. J. G. Wright when he spoke on the use of non-volatile narcotics at the Royal Society of Medicine last week. His paper, read before the section of comparative medicine on Feb. 26th, showed what great advances the practice of anæsthetics has made of recent years in veterinary surgery. Even for minor operations anæsthesia is now usual, and is generally obtained by the combination of narcosis and local anæsthetics. Slow intravenous injection of Nembutal is a highly satisfactory means of getting narcosis in both dogs and cats. For the horse the enormous amounts required, grs. 200 for example, render this drug impracticable economically. All animals have a natural fear of restraint, which at once puts them into a different category from the average normal human subject. Fear and struggling greatly increase the risks associated with inhalation anæsthesia, and it is in abolishing these that the intravenous use of narcotics has so well proved its value in animal surgery. The excitement sometimes witnessed in narcosis was, Prof. Wright said, hard to explain. It shed some light, another speaker suggested, on the psychological causes attributed to the excitement often witnessed in human patients of certain type after consciousness had been abolished and when it was supposed that the "subconscious" mind had

¹ Jour. Amer. Med. Assoc., Feb. 8th, 1936, p. 453.

assumed uncontrolled sway. Avertin, Prof. Wright believes, is not nearly so satisfactory in veterinary as it is in human surgery. Dr. D. H. Belfrage, who gave a capital summary of the use of the non-volatile narcotics by anaesthetists practising among mankind, expressed a preference, on the whole, for avertin, but approved highly of nembutal for young children. Mr. Basil Hughes thought that by a combination of avertin and local anaesthetics he achieved results in abdominal surgery even better, so far as the post-operative state was concerned, than those claimed by Finsterer for splanchnic analgesia. Mr. Hughes related cases showing the possible danger of Evipan, and claimed good results for the use per rectum of a mixture of magnesium sulphate, paraldehyde, ether, and gum acacia. Sir Frederick Hobday, while admitting the excellent work made possible by newer methods, thought that chloroform properly given still held a big place in veterinary surgery.

FUNCTIONS OF THE PINEAL

A CURIOUSLY indecisive controversy has raged for centuries over the functions of the pineal gland. Indeed, it might well be claimed that there is as much experimental evidence for the view of Descartes, who considered the pineal the seat of the soul, as for that of more modern writers who connect the pineal directly with virility. It has been shown that the organ is not essential to life; the curious syndrome of precocious puberty and somatic overgrowth which has been described in young boys suffering from tumour of the pineal has been variously attributed to hyper- and hypo-function of the gland, while Harvey Cushing has attributed these phenomena to secondary effects upon the pituitary. Experimental extirpation of the pineal gland in animals has led to consistently negative results according to certain workers, and to the appearance of macrogenitosomia and obesity in the experience of others. The results of feeding the organ to young animals have been equally confusing. The evidence is in fact conflicting even as to whether the gland has any endocrine function at all. Rowntree and his collaborators¹ have now recorded the results of injection of a pineal extract prepared after the technique of Hanson, using successive generations of rats. These authors had previously found that continuous administration of thymic extract to successive generations of parent rats had resulted in precocity in the offspring, a method which suggested the present experiment. The pineal extract was injected intraperitoneally, and the offspring of the injected rats were mated in pairs; the offspring of these were also injected. The authors found little effect on the first generation under treatment, but succeeding generations have shown progressively more marked retardation of growth and precocity of development from the third generation onward. The resulting animals were therefore "precocious dwarfs"; in addition to having in early life large genitalia suggestive of those seen in macrogenitosomia præcox, the young animals were of bizarre and characteristic appearance, with "short snout, broad face, round head, heavy jowl, and bulging eye." The authors comment on the high incidence of eye disease in these animals, blindness being common, though usually unilateral. Bilateral cataracts, bilateral anophthalmia, and congenital hypertrophy were also observed. These results, which were obtained on several hundred rats, are of peculiar interest if they

can be proved definitely to be due to a substance present in the pineal; they appear paradoxical when compared with the condition associated with tumours of the pineal—the stimulation of bodily growth and of genital development. Some caution must be exercised in accepting the results obtained as due to the action of the pineal itself, however, since the extract used represented an acid aqueous derivative (probably a picrate) and contained 0.21 per cent. free trinitrophenol, whilst it is perhaps significant that more refined extracts were less active.

RESEARCH IN TROPICAL MEDICINE

THE work of the Medical Research Council has never been restricted by territorial limitations, but hitherto the Council have not been able to assist investigations in the tropics except on isolated occasions, although they have regularly made grants for work at home in relation to tropical problems. An intention to take a more active part in field work is indicated by the establishment announced this week of a tropical medical research committee. The decision to appoint this new committee has been taken by the Medical Research Council in consultation with the Colonial Office. It will give advice and direction in the prosecution of such investigations as the Council may be able to promote, at home or abroad, into problems of health and disease in tropical climates, and make suggestions for research in this field. It will include representatives of the Colonial Office and of the Liverpool and London schools of tropical medicine, with other members appointed as individual experts in tropical medicine or in different branches of medical science. The original members are: Prof. J. C. G. Ledingham, F.R.S. (chairman), Prof. A. J. Clark, F.R.S., Dr. N. Hamilton Fairley, Prof. W. W. Jameson, Dr. Edward Mellanby, F.R.S., Miss Muriel Robertson, D.Sc., Sir Leonard Rogers, F.R.S., Dr. H. Harold Scott, Sir Thomas Stanton, Dr. C. M. Wenyon, F.R.S., Prof. Warrington Yorke, F.R.S., and Mr. A. Landsborough Thomson, D.Sc. (secretary).

NON-SPECIFIC IMMUNITY OF THE PERITONEUM

MANY substances have been proposed and used for inducing a pre-operative increase of resistance to bacterial infection in the peritoneal cavity. Some years ago H. L. Johnson^{1,2} reported that amniotic fluid introduced into the peritoneal cavity reduced the incidence of adhesions after Cæsarean section, and that the fluid increased the resistance of the cavity to infection. The same author and his associates³ now present an extensive survey of this latter phenomenon in dogs. They have used a chemically prepared fraction of bovine amniotic fluid and compare its action with that of papain, sodium merthiolate, sodium ricinoleate, and *Bact. coli* vaccine. The merthiolate and saline alone produced very little response. Papain, which has been used to prevent adhesions, dissolved fibrin and the mesothelial layer of the peritoneum, but induced no beneficial inflammatory reaction. The ricinoleate was apparently toxic. *Bact. coli* vaccine induced a large leucocyte response in the peritoneal exudate and in the blood which reached a maximum in 24 hours and was maintained up to 72 hours. The exudate was heavily blood-stained, extensive hæmorrhage had occurred in the subserous tissues, and the

¹ Rowntree, L. G., Clark, J. H., Steinberg, A., and Hanson, A. M.: Jour. Amer. Med. Assoc., Feb. 1st, 1936, p. 370.

³ New Eng. Jour. Med. and Surg., 1928, cxlix., 661.
⁴ Surg., Gyn., and Obst., February, 1936, p. 171.

cellular response was mainly histiocytic. The amniotic concentrate induced a pink exudate; the maximum white cell response occurred in 12 hours, followed by a rapid fall, and a considerable subserous œdema in the peritoneal tissues was followed by an exudate rich first in polymorphonuclear leucocytes and later in histiocytes. The authors favour the amniotic fluid as giving the classic sequence of inflammatory events, while, for example, the coli vaccine and the papain give a distorted response. There does not seem to be adequate ground for believing that the "classic" is any more beneficial in immunity than the "distorted." However, if we assume that a quick leucocyte and plasma response without much damage to the tissues is required for an increase in peritoneal immunity, the amniotic concentrate is to be preferred to the coli vaccine. Dogs thus immunised were tested by the intraperitoneal inoculation of heavy doses of living *Bact. coli*. The survival rates in the various groups were as follows: 7 out of 8 with amniotic fluid concentrate; 6 out of 9 with coli vaccine; and 5 out of 8 controls receiving saline as an immunising agent. The samples are so small that the figures do not indicate with certainty that either the vaccine or the amniotic fluid concentrate are superior to normal saline in immunising value. At present the prophylactic value of the concentrate depends on reports of its clinical efficacy. This is very hard to assess and a significant improvement in the production of immunity by the use of the concentrate in controlled laboratory tests is required before it can be accepted as an agent for general use.

A NEW INTERNATIONAL CONFERENCE ON DANGEROUS DRUGS

ATTENTION has been called again and again in our columns to the appalling extent of illicit traffic in narcotic drugs. While the International Opium Conventions of 1912, 1925, and 1931 have controlled and regularised the legitimate trade in drugs of addiction, there is indisputable evidence that little or no improvement has been effected in suppressing clandestine manufacture and contraband commerce. At a recent meeting of the Council of the League of Nations an important decision was taken in the right direction. On the motion of M. de Vasconcellos it was resolved to summon a diplomatic conference to consider a draft convention which has been prepared for the suppression of illicit traffic in dangerous drugs. Invitations to the conference will be addressed to all States members of the League and also to Germany, the United States, Arabia, Brazil, Costa Rica, Danzig, Egypt, Iceland, Japan, Liechtenstein, Monaco, San Marino, and the Sudan. The Council appointed M. Limburg (Netherlands) president of the conference, and the first meeting will be held on June 8th of this year. A draft convention, which has been twice submitted to the various governments for consideration and criticism, will form the basis for the deliberations of the conference, but it will be open to the delegates to amend or add to it at their discretion. Lord Cranborne, the representative of Great Britain, took exception to a clause in the draft which had been introduced by the committee of experts. This clause would bind the High Contracting Parties to legislate for the severe punishment of those engaged in the "cultivation, gathering and production in contravention of national law, with a view to obtaining narcotic drugs." Lord Cranborne, while agreeing that to make supervision of the drug traffic effective it was necessary to extend it to the "production" of raw materials, regarded the intro-

duction of the clause in question as premature. To meet this objection, which was supported by M. Massigli, the representative of France, the Secretary-General was instructed to ask the various governments for their observations on the new clause introduced by the experts in time for these observations to be circulated before the assembling of the conference. It is to be hoped that the inclusion of the "production" of raw materials may not lead to the difficulties and abstentions which marred the conferences of 1924-25.

TWIN CORONERS?

OUR learned contemporary, the *Law Times*, has published some judicious articles by way of detailed comment on the report of the Departmental Committee on Coroners. In the third and last of these, which appeared last Saturday, it criticises the Committee's recommendation for the creation of a disciplinary tribunal for coroners and also the proposal to confine appointments to solicitors and barristers. On the latter point it observes that the Committee on Coroners does not advocate the dual qualification in law and medicine. How, asks the writer in the *Law Times*, does the lawyer-coroner read the report of a post-mortem examination? He may have served for years as a deputy coroner; he may have taken a course in forensic medicine and may have studied many text-books. But he will never read a post-mortem report with the seeing eye of the medical man who has passed through the hospitals, conducted his own post-mortem examinations, and spent years in post-graduate practice. The coroner, continues the writer, should be able to test the medical evidence out of his own knowledge and experience; otherwise he is at the mercy of the medical witnesses. If a patient has died under an anæsthetic and there has been some carelessness in a matter on which both surgeon and anæsthetist are silent, is the lawyer-coroner likely to detect the fault? The critic finds another advantage in the medical coroner. In the duties of his office the coroner needs to keep in touch with the big hospitals and their staffs, the police surgeons, and the general practitioners of the district. A coroner who is a medical man can talk to other medical men in their own language. Coöperation will be easier and more sympathetic. Coroners have responsibility in the choice between pathologists, police surgeons, and general practitioners for the performance of post-mortem examinations. The proposed institution of a Home Office panel of pathologists for this purpose is dismissed as inadequate to cope with the widespread needs and emergencies. If the coroner's choice remains, it is best exercised by one with medical qualifications.

Having made these points against the Committee's proposals, the writer in the *Law Times* concludes by submitting his own suggestions. As vacancies gradually create the opportunity, he would reorganise large districts under twin coroners. One of the twins would be legally and the other medically qualified. The legal member would take over all the inquests where no medical issue arose; the medical member, who might be called the "medical examiner," would presumably take the difficult medical issues. It is suggested that excellent results might be expected from the collaboration of the best lawyer and the best doctor available for appointment. That may well be; but would not the advantages of such a partnership be more surely and more smoothly obtained if the appointment was given to a single

person who possessed the dual qualification in law and medicine? This dual qualification is already demanded in some of the most important districts. To the General Council of the Bar it is anathema. Apparently the Departmental Committee of Coroners has in this respect yielded to the organised persuasion of the barristers.

CHARLES NICOLLE

Dr. Charles Nicolle, a distinguished bacteriologist possessing an international reputation, has died in Tunis at the age of 70. He was director of the Institut Pasteur de Tunis for more than thirty years, from 1903 till 1936, and editor of the well-known quarterly *Archives* of the Institute, which he inaugurated in 1906. He wrote extensively on the numerous infectious diseases which are endemic in Tunis and many of his researches are of general importance and of permanent value. Among them his greatest achievement was the discovery of the mode of transmission of epidemic typhus, in recognition of which he was in 1928 awarded the Nobel prize for medicine. It had long been known that under insanitary conditions typhus fever spread rapidly amongst prisoners, soldiers, and vagrants, whereas in well-appointed hospitals the disease did not spread. Only those members of hospital staffs were attacked who were occupied in the receiving-rooms or manipulating the patients' clothes and garments, while the clean patients could safely be attended in the general ward. These facts led Nicolle to suspect the body-louse as the vector of the virus and in 1909, in collaboration with Ch. Comte and P. Conseil, he succeeded in proving the correctness of his conclusion by experiments on monkeys. Body lice (*Pediculus corporis*), which had sucked the blood of a monkey infected by the inoculation of blood from a typhus patient, were shown to be capable of transmitting the disease to other monkeys on which they were subsequently allowed to feed. The far-reaching importance of this discovery was demonstrated in an overwhelming manner during the war, when all the armies adopted louse destruction as the essential means of combating epidemic typhus.

From 1909 and until his very last days Nicolle continued his typhus researches, studying the experimental disease in various animal species and the conditions under which it is transmitted. As a result of his experiments with typhus virus and tame rats and mice he formulated a conception of the so-called "inapparent infection," which he defined as an acute infection with periods of incubation and evolution, followed by cure and immunity, though distinguished from the ordinary type of infection by complete absence of general clinical symptoms. In Nicolle's own view this conception is the most important of his discoveries, applicable not only to typhus but also to other infectious diseases (measles, relapsing fever, dengue). Unfortunately his numerous and varied attempts to evolve an efficient method of active immunisation against typhus infection remained unsuccessful. He found, however, in collaboration with Conseil, that serum from typhus convalescents was of prophylactic value, and in 1918, again in collaboration with Conseil, he made the important discovery of the prophylaxis of measles by means of inoculation of serum from convalescents.

Charles Nicolle's fame will not rest merely on his fundamental researches on the transmission of typhus fever by an insect vector, to wit, the louse. This will certainly remain his paramount achievement, in spite of the fact that recent years have

revealed the existence in various parts of the world of many clinical types of typhus-like diseases, spread by a variety of insect vectors. Outside his typhus work, however, must be placed to his credit and that of his school a surprising number of notable findings and observations in the field of preventive medicine. We may note, for example, his studies on Mediterranean fever, on kala-azar and oriental sore, on trachoma and soft sore, not forgetting his careful observations on the behaviour and fate of the relapsing fever spirochete in the body of the louse. An indefatigable worker, he enjoyed the happy collaboration of a band of highly trained experts. The Tunis Institute, in fact, made it its business to illuminate and so to control just those diseases and plagues by which it found itself surrounded. His office of director of a Pasteur Institute, affiliated with the mother institute in Paris and sharing the latter's traditions, he rightly magnified. Only a month ago there appeared in the *Archives* of his institute a long and reasoned article from his pen on the responsibilities of the ideal director of an institute for research in experimental medicine. How is the ideal person to be selected and by whom? By a committee or by a person? When selected and placed in office, what should be his guiding principles in every sphere of his relationships? A pathetic and perhaps prophetic interest attaches to his concluding hints on the training of a successor, a duty that no director, in Nicolle's view, should shirk, if circumstances permit. So studied and ever-progressive should this training in responsibility be, that when the chief comes to retire or die, the change over should take place almost "physiologiquement."

MEASUREMENTS OF RED CELL SIZE

THE Sidney Ringer memorial lecture was delivered at University College Hospital on Feb. 28th on the Measurement of Red Cell Size, by Dr. Cecil Price-Jones. He outlined his technique of measuring red cells and the statistical methods employed to estimate the mean diameter, the degree of anisocytosis, and the degree of microcytosis and megalocytosis shown by the red cells in any sample of blood. He described clearly the normal red cell distribution curve, the factors, such as exercise, that may influence this curve, and the variations from the normal found in pathological conditions.

In introducing the lecturer Dr. Charles Bolton voiced a general feeling in saying that, like Sidney Ringer, Price-Jones had made a remarkable and fundamental contribution to medical science. Ringer's solution and Price-Jones' curves had both become familiar and essential aids to further knowledge of certain physiological and medical problems. Price-Jones has not only devised an invaluable method of studying abnormalities in red cell size but has also determined what the limits of normal variation may be both in size and anisocytosis. These limits are calculated on sound statistical principles and are not the result of a small group of observations only. The method of Price-Jones is admittedly time-, if not temper-, consuming, but it has the extreme advantage over most other methods that the limits of normal variations in cell size determined by the method are known. Mean corpuscular volume can also be used as a measure of cell size. Price-Jones and his colleagues¹ have recently determined the normal limits of variation in cell volume by the method of

¹ Price-Jones, C., Vaughan, J. M., and Goddard, H.: *Jour. Path. and Bact.*, 1935, xl., 503.

Wintrobe. The method is quick, accurate, and easily carried out. It will probably prove the method of choice in the future for estimating cell size in routine investigations. It has however the great disadvantage that it gives no expression to the degree of anisocytosis present in the sample. Increase in anisocytosis is a more delicate measure of variation from the normal than increase or decrease in mean corpuscular size. For research purposes a method that estimates both cell size and anisocytosis is essential. Pijper² claims that his new diffraction apparatus will give reliable measurements both of diameter and anisocytosis; its great advantage is the speed with which results can be obtained; it should be a useful aid in the routine laboratory, especially when the limits of normal variation by this technique have been determined on statistical principles. No diffraction method, however, will give mathematical expression to the degree of microcytosis and megalocytosis present. Though diffraction methods of a refined type and estimations of cell volume may have their value in routine blood examinations, at present the Price-Jones' technique, especially when used in conjunction with Wintrobe's method of volume estimation, stands alone as a method sufficiently accurate for research purposes. It has already achieved, in the hands of its originator, results of fundamental importance.

FOG AND FILTHY AIR

THE public is loudly exhorted in the daily press to become air-minded; and we hope that its new air-mindedness will include concern at the condition of the air. The twenty-first annual report on investigation of atmospheric pollution, issued by the Department of Scientific and Industrial Research,³ shows that the air over the country generally is not becoming cleaner; at least it is not becoming cleaner at those places where deposit gauges have been installed long enough for comparisons. Out of 57 such places only 5 show improvement during the year ended last March. Nor is this the whole tale; for a survey by Mr. B. H. Wilsdon shows that in the past twenty years the amounts of insoluble matters deposited have shown no progressive improvement, although the soluble matters lessened during the first eight years of the investigation. Last year the incidence of days of fog haze, when the soot stain produced by filtering air through paper reached a depth corresponding to over 2 lb. of soot in a cube of air with 100-yard sides, was very variable in places where Owens' air filter records were taken. In London only 19 such "Z" days were recorded at South Kensington and Westminster Bridge, whereas at Victoria-street 52 were noted and at Westminster City Hall 115. At Kew there were 15, at Cardiff none, at Coventry 22, at Stoke-on-Trent 141, and at Edinburgh 68. The irregular distribution over the small area of London covered by filter records is consistent with common experience of the patchy incidence of fogs.

Particular attention has been devoted of late years to the sulphur content of the air, determinations being made at many stations of either the actual volume ratio of sulphur dioxide in air—which is of the order of less than 1 in a million—or of the weight of active sulphur dioxide absorbed by an area of 100 sq. cm. of a lead peroxide surface exposed under a hood protecting it from rain and renewed after a

month's exposure. In all places the variation from month to month is conspicuously seasonal, sulphur, like all polluting matters except those which are insoluble, being in greater amount in air in winter than in summer; but in London, as well as other towns, the amounts in both summer and winter are large, suggesting either that the domestic coal fire is widely continued through the summer or that the southward movement of industrial undertakings is having its effect on London air. This latter view is put forward by a member of the research committee, Mr. J. H. Coste, chemist to the London County Council. Whether it adequately explains the high sulphur content of London air it is difficult to judge; but the annual consumption of coal in the metropolis is very large and there is little reason to suppose that this coal is of specially low sulphur content. So far as we know, the undertakings in London which take steps to remove sulphur from flue gases can be counted on the fingers of one hand.

EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS

A FEW months ago we referred¹ to the work of Dr. Jacques Arnaud, medical director of the Sanatorium Grand Hôtel du Mont Blanc. It may be recalled that his prescription for the early diagnosis of pulmonary tuberculosis was systematic, periodical radiographic examination of the whole community. The same plan is now recommended independently by another tuberculosis specialist in another country. In *Tidsskrift for den Norske Laegeforening* for Feb. 1st, Dr. H. J. Ustvedt passes in review 321 patients examined in the Ullevaal Hospital in Oslo, and gives the duration of the symptoms of these patients before they submitted to a medical examination. It seems that only 83 of them came to examination within a fortnight of the first appearance of symptoms, and that the latent period was three months or more in the case of another 83. Though cough and fever may mark the onset of the disease for the patient, they represent in the eyes of the clinician and pathologist comparatively late stages of an infection which may date back many months, and the disease will be recognised early only when it is sought among persons believing themselves to be perfectly well. Ustvedt therefore recommends Pirquet tests followed by X ray examination of the positive reactors. This system has already been started tentatively in the homes of the tuberculous in Norway, and in Oslo medical students are thus systematically examined with the same object. The procedure is shortly to be extended to other groups so that students in all the faculties can enjoy its benefits. With regard to tuberculin tests, it is curious that whereas in Denmark and Sweden the Pirquet reaction has been found to be so inferior to the Mantoux reaction that the latter is now given the preference in wholesale tuberculin examinations, Norwegians still cling to Pirquet, being convinced that, when it is practised lege artis, it yields figures within 90–95 per cent. of Mantoux figures with 1 mg. of tuberculin. In the other Scandinavian countries comparisons of the two reactions have been much less flattering to Pirquet. These intra-Scandinavian discrepancies may reflect want of uniformity of technique, or, as Ustvedt believes, the fact that bovine tuberculosis exists in Denmark and Sweden but is almost non-existent in Norway.

PROGNOSIS

A Series of Signed Articles contributed by invitation

XCI.—PROGNOSIS IN SPINAL CARIES

PROGNOSIS in spinal caries depends (1) on the natural resistance of the patient, (2) on the method of treatment adopted, and (3) eventually on complications and the degree of deformity remaining. The disease may occur at any age and is most dangerous in weakly infants with bad family history, in whom the danger of tuberculous meningitis or general dissemination is very real. There is much controversy as to the relative values of extreme conservatism without operation and conservative treatment assisted by bone-grafting or bone-fusing operations of that part of the spine affected. The position is, briefly, that properly applied conservative treatment with rational orthopædic measures but without operation is certain of considerable success, but that treatment may be shortened in selected cases by operative measures. Immediate mortality is undoubtedly least when careful non-operative conservative treatment is alone applied. Patients with severe deformity, which incidentally should never arise if early treatment is undertaken, have a lessened hope of longevity from mechanical reasons which predispose to death from complications such as pneumonia. Such patients however can hardly be helped by operative treatment.

Below are tables giving mortality statistics of all my own cases treated at Treloar Cripples' Hospital from September, 1908, to March, 1935, but excluding cases in private practice or treated at any other hospital with which I am associated.

SPINE

Total number of cases admitted during the period	1666
Cases discharged to March 31st, 1935	1582
Deaths to March 31st, 1935	61 (3.8%)
Average stay in hospital of fatal cases	410 days.

Causes of Death

Miliary T.B. and meningitis	32 (2.02%)
Sepsis and amyloid disease	16 (1.01%)
Other causes	13 (0.82%)
Diphtheria	1
Morbus cordis	3
Nephritis	1
Ketosis	1
T.B. carditis	1
Post-operative shock (laminectomy)	1
Pneumonia	1
Broncho-pneumonia	1
Influenzal pneumonia	1
Intestinal obstruction	1
Hæmorrhagic measles	1

Age-periods.	Deaths.	Average stay in days.	Miliary T.B. and meningitis.	Sepsis and amyloid.	Other causes.
1-5	26	257	19	2	5
6-10	26	592	11	8	7
11-16	9	466	2	5	2

Relative Frequency of (a) Miliary T.B. and Meningitis, and (b) Sepsis and Amyloid Disease as Causes of Death at Different Age-periods in Spinal Caries

Age	1-5	6-10	11-16
Miliary T.B. and meningitis (per cent.)	73.1	42	22.2
Sepsis and amyloid (per cent.)	7.7	30	55.6

Summary

Total admitted.	Total discharged.	Total died.	Average stay in days of fatal cases.	Death percentage.
Spine 1666	.. 1582	.. 61	.. 410	.. 3.8

Mortality is highest in the age-period 1-5 and the commonest cause of death in this age-period is menin-

gitis and general tuberculous dissemination. As age increases the danger of meningitis diminishes, but deaths from sepsis increase. Other causes may be almost disregarded, as they are incidents arising in any child's life though naturally more serious in a child already infected with tuberculous disease.

This comparatively low mortality in children, many of whom arrive for treatment with advanced disease, often complicated by abscess or sinus formation and sometimes paraplegia, may be ascribed to the rigid conservatism practised under exceptionally good climatic and hygienic conditions. In children I am definitely opposed to stabilising the spine by bone-grafting or fusing while the disease is active and consider such operations not generally indicated when the disease is arrested. An exception to this rule occurs in the case of children of poor musculature where it may not be possible to supervise efficient splinting over a sufficiently long period after discharge. In such cases rapid increase of deformity may arise, which might be avoided by osteo-synthesis.

In adolescents and adults Albee's operation (or some modification) for stabilising the spine is increasingly popular amongst many surgeons as an alleged means of reducing the period of treatment for and the danger of later increase of deformity or recurrence of the disease. The mortality is undoubtedly raised in those submitted to operation unless patients are carefully selected, guarded from intervention in the acute and progressing stage of the disease, and made to take adequate rest over a sufficiently prolonged period.

These operations will not with certainty arrest the disease and in the course of my work I have been impressed by the large number of patients I see who had been discharged too soon and in whom abscesses or paraplegia had compelled return to institutional treatment, often without the knowledge of the surgeon who performed the operation.

COMPLICATIONS

The presence of a *closed tuberculous abscess* associated with a tuberculous lesion of the spine is of little moment if it can be successfully aspirated and secondary infection or sinus formation avoided. If secondary infection occurs the outlook is grave. Free drainage is essential and immediate treatment with autogenous vaccines at this stage is helpful. All too often, however, fever and toxæmia enfeeble the patient, the course of treatment frequently becomes long and tedious, and amyloid disease may follow. In the latter case, the prognosis is definitely bad, though I can recall a few such patients who have recovered. Secondarily infected sinuses often heal with extreme difficulty, some never heal, and then the patient may recover or survive for many years with discomfort and often, though not necessarily, in a state of chronic invalidism.

An abscess is a serious complication when it forms in the region of the spinal canal and when by reason of the pachymeningitis it produces, or by direct mechanical pressure, it involves the spinal cord. The mid- and upper dorsal regions of the spine are the commonest situations. Of 134 cases of paraplegia occurring at the Treloar Cripples' Hospital, 14 are still under treatment, 5 died, 6 were removed, 24 were unimproved, and 85 were discharged walking after conservative treatment.

Paraplegia from true tuberculous pachymeningitis is a late manifestation; its onset is insidious, it tends to progress rather than resolve and the prognosis is bad. Of 26 such cases included in the total of 134, 12 recovered, 11 were unimproved, 2 were removed, and 1 died.

DEFORMITY

The prevention of deformity, or its correction, if that is possible, should be an essential aim in treatment. Both may be ensured in a large number of cases if the patient is immobilised, hyperextended, and treated at first and for many months in the dorsally recumbent position. The cervico-dorsal region of the spine is the most difficult one in which to prevent or correct deformity, and if much deformity exists before effective treatment is initiated, correction is almost impossible. The prevention or attempted correction of deformity should be urged not only on aesthetic grounds, but because with much kyphosis there is embarrassment and displacement of the viscera, especially the thoracic viscera, with consequent distress to the patient and liability of intercurrent, especially respiratory, disease. A strong dorsal musculature is of great assistance in maintaining the spine erect, and for that reason open-air treatment and back-raising exercises with the patient prone are of especial value in the last stages of institutional treatment. Efficient after-care and well-applied and fitting spinal jackets are of immense importance

at this period, and in cases of weakened muscles spinal osteosynthesis has its most important indication.

ASSOCIATION WITH OTHER TUBERCULOUS LESIONS

Occasionally, though rarely, one finds patients who will fail to respond to any form of treatment and in whom other lesions develop. For these, prospects of recovery are poor, though, at times, from some reason, possibly a suddenly acquired immunity, progress of the disease is checked and recovery follows.

In children, multiple lesions associated with spinal caries lengthen the period of treatment required but do not usually jeopardise cure. Associated pulmonary tuberculosis is a serious but not unconquerable complication, and I have known adults who, as the result of acquiring spinal caries following pulmonary tuberculosis, have recovered completely from both, largely as the result of the enforced rest which the spinal lesion necessitated.

I am indebted to Mr. H. H. Langston, R.M.O., at the Treloar Hospital, for collecting and analysing the incorporated statistics, and to Dr. Churchill, late R.M.O. to the hospital, for the analysis of the paraplegia cases which is discussed fully elsewhere (*St. Bartholomew's Hosp. Jour.*, October, 1935).

HENRY GAUVAIN, M.D., M.Chir., F.R.C.S.,
Medical Superintendent of the Lord Mayor Treloar
Cripples' Hospitals, Alton and Hayling Island,
and of the Morland Clinics, Alton.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdrs. H. H. Babington to *Pembroke*, for R.N.B., Chatham, and as Ophthalmic Specialist; M. Brown to *Victory* for Haslar Hospl.; and O. D. Brownfield, O.B.E., to *Pembroke* for R.N. Hospl., Chatham.
Surg. Lt. (D) S. R. Wallis to *Pembroke* for R.N.B.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdr. R. B. H. Wyatt placed on the Retd. List.
Surg. Lt. C. J. T. Watson to *Curacoa*.
Surg. Sub-Lts. J. A. Shepherd to *Royal Sovereign*, and R. F. B. Bennett to *Victory* for R.N. Hospl., Haslar.
Proby. Surg. Lts. to be Surg. Lts.: A. B. Concanon, W. G. Gill, and N. A. Vernon.
Proby. Surg. Sub-Lt. G. S. Irvine to be Surg. Sub-Lt.

ARMY MEDICAL SERVICES

Lt.-Col. S. W. Kyle, R.A.M.C., to be temp. Col. whilst empld. as A.D.M.S., 5th Div., Jan. 10th, 1936. (Substituted for notification in the *Gazette* of Feb. 4th.)

ROYAL ARMY MEDICAL CORPS

Short Serv. Commissions: Lt. B. d'E. Barelay to be Capt; Lt. (on prob.) A. H. T. F. Fullerton is restd. to the estab. and is confirmed in his rank; and R. E. Waterston to be Lt. (on prob.).

REGULAR ARMY RESERVE OF OFFICERS

Col. E. W. Powell (late R.A.M.C.), having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY

Capt. A. N. B. Odbert to be Divl. Adj. 46th (N. Mid.) Div., vice Maj. H. A. Rowell, M.C., vacated.
Lt. P. Spence to be Capt.

The King has conferred the Efficiency Decoration upon the undermentioned officers under the terms of the Royal Warrant dated Sept. 23rd, 1930: Lt.-Col. J. P. Clarke, Lt.-Col. J. B. Scott, M.C., Maj. A. H. D. Smith, M.C., Maj. A. G. Williams, O.B.E., Maj. P. Lloyd-Williams, Maj. C. W. Healey, M.C., and Maj. James Duncan Hart, M.C. (deceased).

TERRITORIAL ARMY RESERVE OF OFFICERS

Lt. A. Menzies, from T.A. Res. of Off. (9th Bn. A. and S.H.), to be Capt.

ROYAL AIR FORCE

Squadron Leader T. J. X. Canton to R.A.F. Station, Manston, for duty as medical officer.

Flight Lt. J. Hutchieson is promoted to the rank of Squadron Leader.

Wing Comdr. J. Rothwell is placed on the retired list at his own request.

Flying Officer S. R. C. Nelson to No. 6 Flying Training School, Netheravon.

Dental Branch.—Flight Lt. J. E. Willoughby, L.D.S., relinquishes his non-permanent commission on account of ill-health.

INDIAN MEDICAL SERVICE

Capt. G. J. Joyce to be Maj.

DEATHS IN THE SERVICES

The death occurred at Tunbridge Wells on Feb. 27th of Surgeon Captain JOHN EDWIN COAD, R.N., retd. He qualified M.B. Durh. 1885 and M.R.C.S. Eng. 1886, having been educated at Newcastle-on-Tyne and St. Thomas's Hospital, London. In 1887 he resided at York and soon after joined the Navy. In 1899 he was appointed Staff Surgeon in *Barracouta*, a twin-screw cruiser, Cape and West Africa Service, attained the rank of Fleet Surgeon in February, 1903, and retired with the rank of Surgeon Captain in July, 1917, receiving a medal for war service.

LONG RECORD OF HONORARY SERVICE.—At a meeting of the executive committee of Worcester Royal Infirmary to consider the appointment of a successor to Mr. Mark Bates, who is an honorary surgeon but is undertaking other work at the hospital, it was stated that the Bates family had in all given 77 years of honorary service to the hospital. The late Mr. Tom Bates gave 37 years' work, his son, the present senior surgeon, has given 27 years, while Mr. Mark Bates has given 13 years.

SPECIAL ARTICLES

IVAN PETROVITCH PAVLOV

DURING the last twelve months of Pavlov's life probably more people who were interested in his work had the privilege of seeing him and hearing him speak than in any other year. The summer of 1935 is memorable both because of his visit to this country for the International Neurological Congress and because of the holding in Russia of the International Physiological Congress. The name of the great physiologist dominated these gatherings, which were attended by representatives from all over the world, and their chief interest to many lay in the opportunity to "see Pavlov." Those who met him on these occasions must count themselves fortunate, for he died in Leningrad on Feb. 27th, at the age of 86.

Pavlov was born in September, 1849, in the small city of Riazan in Russia. His family were poor, but his father was a country priest and the foundations of his education were laid in the church school from which he passed to the theological seminary. It seems that this differed from other schools in that the boys were encouraged to develop their natural inclinations instead of being forced up to the same standard in all subjects. Pavlov became interested in the natural sciences, and at the age of 21 entered what was then St. Petersburg University, and studied under Mendeleef and other eminent teachers.

Later, in the Medico-Chirurgical Academy, he came in contact with von Cyon whose stimulating personality had much to do with determining his future career; and after graduation in 1879 he continued research work in the Military Medical Academy under the physician Botkin, obtaining the degree of M.D. in 1883 for a thesis on the efferent nerves to the heart. In 1884 came the opportunity to go abroad, and when he returned to his former position two years later his experience had been enriched by work done in the laboratories of Ludwig and Heidenhain.

Thereafter followed his classical contributions to the physiology of digestion, and by 1897, when he published a monograph on the subject, his reputation was international. Meanwhile, at the age of 41, he had been appointed professor of pharmacology in the Medical Academy, and then to the chair of physiology in the new Institute of Experimental Medicine, built by Prince Alexander of Oldenburg. In 1897 he obtained the chair of physiology in the Medico-Chirurgical Academy, relinquishing his professorship of pharmacology, but he still retained his other two posts when, in 1907, he was appointed one of the four scientific members of the St. Petersburg

Academy of Sciences, and therefore had charge of three laboratories. Most of his personal research was done in the Institute, now known as the All-Union Institute of Experimental Medicine, of which he was latterly honorary director, as well as director of physiological laboratories in the Russian Academy of Sciences.

Although Pavlov emerged after the revolution in more or less the same posts as he had held previously, he suffered more than a change of titles during that difficult time. "Like other scientists he suffered much . . . having to carry on his experiments without heat or light, and drawing his main food supply from a little patch of potatoes which he tended himself. But his only complaint was that,

with other members of the Academy of Sciences, he had to take his turn in guarding firewood stacked outside the Academy for six hours at a stretch."¹

Pavlov, however, was no stranger to hardship and was enabled to survive this period of drudgery and want which must have recalled his earlier struggles. Until he obtained his first professorial post his life had been a continual battle with poverty and difficulties which to a lesser man would have been insurmountable. The animals he used for his researches into the circulation and for his earlier experiments on digestion were tended by himself and his wife in their own home, and comfort was sacrificed to the thoroughness upon which he insisted in every branch of his work. During his second period of adver-

sity he made no secret of his disapproval of the prevailing régime and its principles, but he was treated with tolerance and later received at the hands of Lenin every encouragement and opportunity to pursue his important work. It would be ungenerous to analyse the motives for this policy, which was never varied up to the time of Pavlov's death. Last year, on his 85th birthday, he was given a pension of 20,000 roubles, and a million roubles for his laboratories. He had but little interest in politics as such, and it is said rarely read a newspaper. He criticised the government in so far as they made academic appointments on political grounds, and more fundamentally because he believed the philosophy they adopted to rest on a faulty biological basis; nevertheless, in his welcome to the Physiological Congress last year he fully identified himself with the policy of his country.

Long after these details of Pavlov's eventful career have been forgotten his contributions to medical science will perpetuate his name. In the space of ten years he reduced the unexplored field of digestive secretion to an orderly pattern of reflexes,

¹ The Times, Feb. 23th, 1936.

and definitely established the value of applying to physiology the methods of aseptic surgery. His fistulæ were carefully made, and the scrupulous after-care of the animals enabled him to keep them alive until they were, to all intents and purposes, restored to normality. The influence of experimental conditions upon his observations was reduced to a minimum. The importance of his famous operation for separating off a pouch from the stomach, in which the gastric secretion could be studied uncontaminated with food, rested upon the "normality" of the pouch. Its nerve- and blood-supply were left intact, and no detail was overlooked which would serve to make it in all respects a faithful miniature of the stomach itself. Pavlov never made the mistake of forgetting that the organ he was studying was but a part of the whole animal, and that if this was not in perfect condition the conclusions would be subject to all manner of reservations. He worked out in great detail the responses of the salivary and gastric glands to the sight, smell, and taste of food, and showed how the type and quantity of secretion could vary with the kind of food administered.

THROUGH PHYSIOLOGY TO PSYCHOLOGY

It is noteworthy that although Pavlov's work had been directed up to this time towards problems concerning the circulatory and digestive systems, he approached them from the point of view of their nervous control. In 1902 Bayliss and Starling demonstrated the copious secretion of the pancreas in response to the hormone secretin, and Pavlov had to revise many of his conclusions in view of this hitherto unsuspected mechanism for coördination. He foresaw that development for the next few years would be likely to be along chemical lines, and it is probable that his disinclination for this type of work was one of the factors which turned his attention to the nervous system itself.

At all events, the next thirty years saw a direct attack on the physiology of the cerebrum whose results transcended in importance anything which Pavlov had yet done. He noticed that an organ could be activated reflexly not only by its normal stimulus, but, under certain circumstances, by all kinds of stimuli not usually associated with it. Thus if a dog was always fed in a routine manner by the same attendant, dressed in the same way, it would begin to secrete saliva before tasting the food, and also when the attendant came without food. In other words an entirely new reflex—a conditioned reflex—had been laid down, the sight of a particular person becoming an adequate stimulus for the secretion of saliva. A salivary fistula enabled Pavlov to assess the quantitative value of the response by measuring the rate of secretion, and he showed how this could be brought about by stimuli applied to any sense-organ. Once the method of producing conditioned reflexes had been established, the next step was to investigate their properties—how they were modified by intercurrent stimuli and the laws determining how they could be reinforced, destroyed, or inhibited. The fruitfulness of experiments on inhibitory phenomena alone was surprising, and Pavlov showed, among other things, how inhibition could be built up so strongly as to produce sleep.

The technique of the experiments is further illustrative of Pavlov's genius in obtaining reliable information about a single organ from the intact animal. This time the problem was not surgical, but rather one of designing apparatus and perfecting routine. The brain was "isolated" by keeping the animal under absolutely constant conditions and

ensuring that the experimental stimuli to which it was subjected were the only unusual events in its life. This required extraordinary precautions including the building of special laboratories and the rigid training of assistants. It might have been contended, with some show of reason in regard to his earlier experiments on digestion, that Pavlov owed his success to his amazing manual dexterity and operative technique, which were the envy of his assistants. In considering his work on conditioned reflexes, however, it becomes apparent that the factor determining the outcome of his researches was always his method of attacking a problem. His life was literally devoted to the search for truth, and in achieving his ends he used no instrument which he had not perfected to the highest possible degree. "A superb experimenter, combining the talent of a magnificent surgeon and a shrewd observer; a dynamic lecturer, surpassed only perhaps by Maximot in logic and the use of language; a powerful thinker, never interested much in priority, never influenced by any authority, he understood only the logic of facts."²

It is unnecessary nowadays to stress the value of this objective method of approach in the study of the mind. Pavlov believed that all acquired habits and training depended on chains of conditioned reflexes, and that his experiments on dogs provided the clue to the type of activity taking place in the human cortex. By comparing the reactions of different animals to his experiments, the readiness or otherwise with which they formed conditioned reflexes, and the subsequent stability of the reflexes, he was able to divide dogs into four groups which bore a close resemblance to the "choleric, phlegmatic, sanguine and melancholic" temperaments of man. By associating one kind of response with a conditioned stimulus of certain characteristics, and an incompatible type of response with a closely related but slightly different stimulus, he trained his dogs to an astonishing pitch of discriminative ability. If overtaxed, for instance by persistently having to differentiate between two musical notes varying by only a few vibrations, they broke down and became definitely neurotic, losing temporarily all vestige of their training. Inhibitory reflexes were always the greatest sufferers under such conditions.

Clearly this was leading Pavlov into the realms not only of normal but of abnormal psychology. He related the original "type" of dog to the disturbance most likely to develop, and was able to produce states analogous to hysteria, catalepsy, and many of the neuroses and psychoses. Visitors to Leningrad last year were able to see the groups of orphan babies whose development he was observing, and the patients he was investigating in the Psychiatric Polyclinic where he had charge of 25 beds.

A LEGACY TO SCIENCE

The logical development of Pavlov's work has never faltered, and at the time of his death he was the centre of a vast and still growing organisation of research which had sprung from his first modest experiments. It is doubtful whether the usefulness of the methods he has introduced will ever be exhausted, while the results so far attained have already made a permanent impress on several branches of learning, including some previously immune to experiment.

² Stavraky, G. W.: Arch. Neurol. and Psychiat., 1935, xxxiii., 1082. Most of the biographical data in the present sketch were obtained from this account of Pavlov's life. The photograph was taken at the Rockefeller Institute, during a visit to New York, by Mr. Louis Schmidt.

His powerful, yet lovable personality, will not be forgotten by those of the present generation, while the intense loyalty and admiration he evoked in all who worked with him bids fair to make that personality legendary. Known in every civilised country in the world, he was awarded many foreign and international distinctions, including the Nobel Prize in medicine and physiology in 1904. In this country he was a foreign member of the Royal Society, whose Copley medal was given to him in 1915, and an honorary fellow of the Royal College of Physicians.

MEDICINE AND THE LAW

The Nottingham Nursing-home Trial

Nurse Waddingham, an unregistered nurse, was found guilty last week of the murder of Ada Baguley at a home carried on at Devon-drive, Sherwood, Nottingham. In the organs of the dead woman's body $4\frac{1}{6}$ grains of morphine hydrochloride were found. One grain was a possible fatal dose. The jury may well have been satisfied that Ada Baguley died on Sept. 11th of morphine poisoning: they had also to be satisfied that the accused administered the morphia and administered it with intent to murder. A will made by the deceased on May 7th in favour of the accused was suggested as a motive. When told, on Sept. 24th, that morphia had been found in the body, Nurse Waddingham said: "I have never given Miss Baguley any morphia: I have never had any in the house. . . . Apart from the medicine prescribed by the doctors and aspirin, she has had no other medicine." Later she admitted that she had morphia, but she said that Dr. Manfield (the deceased's medical attendant) had prescribed it and she had not mentioned the fact because he asked her not to. This statement Dr. Manfield denied. There was a further vital conflict of evidence between the accused and the medical attendant. The accused said that on August 27th Dr. Manfield gave her 6 tablets which she knew were morphia. Dr. Manfield said that he did not and that there was nothing in the patient's condition which would lead him to leave morphia at the home. Inasmuch as the defence contended that the accused administered the morphia to alleviate violent pain, it was important that Dr. Jacob, who had attended Miss Baguley previously, visited the patient in the third week of August and saw no reason to prescribe morphia. The drug indeed, according to the accused, was mentioned for the first time on August 27th. She said that on Sept. 2nd Dr. Manfield gave her 4 more tablets of morphia, without being asked and without asking whether she had used any of the previous 6. Dr. Manfield denied this too. Nurse Waddingham said she had given the first two tablets to the deceased on Sept. 7th. She said Miss Baguley had been poorly from some date in August and one of the symptoms was a severe abdominal pain. She gave the morphia tablets for three nights because Ada Baguley suffered sharp abdominal pains, yet on Sept. 10th she cooked her a heavy meal of pork (two helpings), baked potatoes, kidney beans, and fruit pie. The patient died next morning. Dr. Manfield was sent for: he found the body still warm: rigor mortis had not set in. He certified cerebral hæmorrhage as the cause of death. This, as the post-mortem examination showed, was wrong. Mr. Justice Goddard remarked that no blame could here be attached to the doctor for the error. If a patient dies of a stroke,

the doctor can act on what he is told and he can but ask those who were present at the death and form his own opinion. The doctor was dealing with a patient suffering from a disease with which apoplectic disorders could be connected, and he was told that she had suffered from strokes before. There were, as the judge observed to the jury, many points at which the evidence was in Nurse Waddingham's favour. The inconsistencies in her story and the conflict between her evidence and that of Dr. Manfield seem to have established her guilt.

One point of special significance was the introduction of evidence that Ada Baguley's mother, an inmate of the same home, had apparently died of a poisonous dose of morphine. Dr. Roche Lynch described the discovery of pseudomorphine in her exhumed body. How was this evidence of another death legally admissible on the charge in respect of Ada Baguley alone? We noted in this column a few weeks ago the case of *R. v. Mortimer*, where a soldier who stole a car ran down a girl on a bicycle and was charged with murder. Although strictly the witnesses should have spoken only of this incident, the court admitted evidence that, earlier and later, the soldier had driven the car at other people on bicycles. These facts were held to be admissible in order to show systematic purpose and to negative the defence of accident. So also in the Baguley trial the evidence of a parallel case was allowed in order to prove intent. The jury was warned (for what such warnings may be worth) that the evidence of Mrs. Baguley having died of morphine poisoning was not to be accepted by them as showing that Nurse Waddingham was a woman who poisoned other people. The evidence of the mother's death was material, said the judge, only in this way—if the jury thought the administration of morphine to the mother might not have been innocent, they could ask themselves whether the giving of the drug to the daughter was done with the innocent intention to relieve pain or with the criminal intention of taking life. Whether juries can master these subtleties or no, such is the law. The same point arose in the *Armstrong* case in 1922. On a charge of murder by arsenical poisoning in the month of February, it was proved that the prisoner had arsenic in his possession both before and after that date. His defence was that death was due to suicide and that his possession of arsenic was for the innocent purpose of killing weeds. Evidence that he tried to poison somebody else with arsenic in October was held admissible as tending to show that the possession of the weed-killer at the earlier date was not for an innocent purpose.

There is to be an appeal in *R. v. Waddingham*. It has been stated in the daily press, on the authority of the solicitor for the defence, that one ground of appeal will be the fact that the judge told the jury it was either murder or nothing and did not deal with the possibility of manslaughter through the negligent administration of morphia to the patient. The discussion on this and other points must be awaited.

Hospital's Liability for Child Patient

A verdict of £500 damages (with costs) was entered last week against the Rochester and Chatham Joint Hospital Board, as managers of St. William's Hospital, Rochester, in an action for damages for personal injuries to a child patient. A boy of 7 was received in the scarlet fever ward on the ground floor. On the afternoon of his first day in the ward, having been placed in a bed a few feet from a window, the lower part of which was open, he somehow sustained

injuries by falling out of the window to the ground below, a distance of about 17 ft. He suffered from shock and was kept three weeks longer in hospital; his forehead was disfigured and both feet are now flat and require special supports. The boy's father, who brought the action, said the hospital and its staff were negligent in leaving the patient unattended near the open window. The defendants denied the allegation and alternatively contended that, if they had been negligent, the child had jumped out of the window in the endeavour to return home, taking the risk of the jump and contributing by his own negligence to any harm which he received. The verdict of the jury indicates that they did not accept the contention of contributory negligence.

There are interesting legal decisions on the question whether, or how far, a child is capable of negligence. *Lynch v. Nurdin* (1841) is the classic case. An egg-merchant's cart was left unattended beside the pavement in Compton-street, Soho. Children played with it. One little boy was climbing into the driver's seat when another little boy tugged at the horse's bridle. The first boy consequently fell and was injured; his father successfully claimed damages and it was considered that the child had not been guilty of contributory negligence but had merely obeyed a child's natural instincts of play. The inference is that a child in such cases is to be judged as a child and must not be expected to have the mature judgment of a grown-up person. On the other hand he may be unable to recover damages if he has done what he knew to be naughty. The jury must consider his age and his ability to look after himself. Where a machine for oil-cake crushing was left standing in the street with the handle not fastened up and some schoolboys played with it, one turning the handle while another thrust in his fingers, the owner of the machine was held not liable. This decision has been severely criticised. Modern cases are more sympathetic to the child, where the object is dangerous in itself, especially when it offers some allurements to the infant mind. Special considerations arise where the child meets its injuries while trespassing. The Central London Railway, for instance, had a moving staircase in a booking-hall close to the street. It attracted children from the street, who were frequently driven away. One child was injured while thus trespassing and the court held that the company was not liable. As regards the duty of hospital staff to foresee the natural temptations of an open window near a child's bed, the same duty would presumably exist in the case of an adult patient of known abnormality of mind.

Fines for Dangerous Drugs Act Offence

Last week the Marylebone magistrate imposed fines amounting to £150, with 30 guineas costs, upon a physician and surgeon for failing to keep records as required by the Dangerous Drugs Regulations. The prosecution concerned 398 grains of morphine sulphate. It was said that the defendant had given one woman 190 grains at one time and another person 72 tubes. Both these patients were known to be drug addicts. It was further said that the prescriptions showed that the doctor, rather than reduce the dosage, had been increasing it; 1 grain had been increased to 7 or 10 grains in a few months. Counsel for the defence submitted that the large supply in one instance had been for a patient who was going on a cruise. The magistrate said it was a case of such gravity that, if the money was not paid by the end of the day, the alternative would be imprisonment.

THE IRISH HOSPITALS

(FROM OUR DUBLIN CORRESPONDENT)

AFTER the passing of the Public Hospitals Act, 1933, the Minister for Local Government and Public Health appointed a commission, under the chairmanship of Mr. Michael W. Doran, to investigate the hospital and nursing facilities existing in the Irish Free State, to advise him as to the improvement of such facilities, and generally on any matter relating to the administration of the Hospitals Trust Fund. The first general report of the commission was issued last Saturday, and is attracting much attention both from the public and the medical profession. The commission has shown industry, insight, and vision in its work, and has made a thorough and discriminating investigation of the whole hospital problem. The acceptance or rejection of the recommendations in the report is a matter for the Minister, but the report will always be of value as a historical document, both for its survey of the present position and its suggestions for the future. It is a closely printed volume of over 200 pages and only a brief abstract can be given here.

HOSPITALS IN THE FUTURE

The hospital system which the commission visualises for the future would consist of district hospitals, county hospitals, and regional hospitals. The district hospitals, of which there might be several in a county, would deal with such acute medical cases and receive maternity and surgical cases as could properly be treated without special services of any kind. The county hospitals—one in each county remote from a regional hospital—would cater for acute medical and surgical cases. Regional hospitals would be at the teaching centres of Dublin, Cork, and Galway, and also at Limerick and possibly at Sligo. They would deal with acute or obscure medical and surgical cases.

CONDITIONS IN DUBLIN

A careful survey is given of the existing facilities in the several centres, and a discussion follows of the improvements and additions considered desirable. The problem of Dublin is of most interest. In the opinion of the commission the number of general hospitals in Dublin is too large, and many of the hospitals are too small, the number of beds ranging from 40 to 399, excluding the poor-law hospital which has 1582 beds. The commission recommends that the ten clinical hospitals should be reduced to seven by the amalgamation of four hospitals on the south side of the city—the Meath, Mercer's, Sir Patrick Dun's, and the Royal City of Dublin. Of these four the three last mentioned have put forward a scheme of amalgamation, and in regard to the Meath, the commission does not think that its obligations are sufficient to exclude it from the scheme, and advises against any large expenditure on it should it remain independent. St. Vincent's Hospital has considered removal from its present site in St. Stephen's Green to a site on the outskirts of the city, and should be considerably enlarged. The commission is not concerned with the Adelaide Hospital which has not applied for any grant from the Hospitals Trust Fund. The commission does not recommend any interference with Dr. Steevens' Hospital, the only remaining hospital on the south side of the city, its location and the nature of its activities rendering its inclusion in a scheme of amalgamation inadvisable. On the north side of the

city the Richmond Hospital and the Mater Misericordiae Hospital should both be considerably enlarged. The Charitable Infirmary (Jervis-street Hospital) should remain to carry on its work as at present, being in fact the principal accident hospital of the city. To sum up, the scheme provides for four hospitals of 550 beds each, two on the north side and two on the south, together with Dr. Steevens' and Jervis-street, and presumably the Adelaide, as at present. It is further recommended that these voluntary hospitals should take over the care of such acute cases as are at present given care in the poor-law hospital.

FEVER HOSPITALS—ACCOMMODATION FOR TUBERCULOUS CASES

The commission proposes the abolition of the fever wings attached to certain of the voluntary hospitals and the abandonment of the present fever hospital in Cork-street in favour of a new fever hospital to be built in or near Dublin. This proposal has already been approved by the Minister who has introduced a Bill to the Dáil to give it effect. It is not intended to amalgamate the three maternity hospitals of Dublin. One of them, the National Maternity Hospital, has just completed a new and greatly enlarged building. Enlargement of the Rotunda is recommended, and the abandonment of the present building of the Coombe with its removal and rebuilding on the site now occupied by Cork-street Hospital.

With regard to hospital accommodation for tuberculosis, the commission declares that there is a definite shortage of bed accommodation in the country, both for pulmonary and for non-pulmonary cases. The report recommends an open-air unit of 100 beds at Our Lady of Lourdes Hospital, County Dublin, and open-air hospitals of 50 beds each at Cork and Galway; and also a special tuberculosis hospital in Dublin. There is need for further special provision for dealing with cancer, but the commission is not yet in a position to make a recommendation.

PROPOSED GRANT FOR MEDICAL RESEARCH

The commission advises that a provisional grant of £10,000 a year should be given to a Medical Research Council, at present being constituted, for the purpose of medical research. The need for developing the social service side of hospital work is strongly stressed, and attention is drawn to the need for almoners' departments in nearly all the Dublin hospitals.

The commission makes a clear statement of the present financial position of the Hospitals Trust Fund and of the cost of carrying out the recommendations now put forward and meeting commitments already entered into. Considering estimates for proposed expenditure and endowment a sum of £7,900,000 will be required to enable the recommendations in regard to voluntary hospitals to be realised. Of this £3,383,853 is at present available. Recent sweepstakes have shown that the share of the voluntary hospitals from each sweepstake averages some £363,000. It is impossible to prophesy whether this return will be maintained or not, but even if it should be, it is clear that it will be some four years before the necessary fund is accumulated. The commission, therefore, believes that caution should be exercised in regard to beginning building schemes which would require a large capital for their completion until it is reasonably sure that sufficient funds will be available. With care, however, an advance might be steadily made without discrimination against any particular hospital or undertaking.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE CORPUS LUTEUM AND PREGNANCY

Dr. J. M. Robson spoke to the Edinburgh Pathological Club last week on his investigations into the activity of the corpus luteum in pregnancy. Among animals, he said, three types can be recognised: (1) those in which ovulation occurs only after mating; (2) those in which ovulation occurs without mating but in which a physiologically active corpus luteum is not formed unless mating takes place; and (3) those in which ovulation and the formation of an active corpus luteum occur spontaneously. In some species (e.g., man) the duration of activity of the corpus luteum of pseudopregnancy is much shorter than that of pregnancy, whereas in others (e.g., dog) the periods are of roughly equal length. In some animals (e.g., the mare) the corpus luteum degenerates in the early stages of pregnancy, and this raises the question how far it is necessary that luteal secretion should continue until term. The available data show that in some species the corpus luteum is essential during almost the whole of pregnancy, but in others (man, horse, cat, and guinea-pig) its removal does not necessarily lead to abortion. The luteal hormone in Dr. Robson's opinion is probably secreted by the placenta as well as the corpus luteum, and the importance of the latter in different species during pregnancy may vary inversely with the capacity of the placenta to produce progesterin. During pregnancy this hormone is essential for the preparation of the endometrium after fertilisation, for implantation itself, and probably for the subsequent nutrition of the developing embryo and placenta. It also inhibits the reaction of the uterine muscle to oxytocin and controls the spontaneous rhythmic activity of the uterus—in these respects antagonising the action of oestrin. When the pituitary is essential to the maintenance of pregnancy, its function consists in maintaining the luteal secretion, and pregnancy can actually be maintained in the hypophysectomised rabbit by the administration of the pure hormone progesterone. Experiments now in progress, said Dr. Robson, further show that the structure and secretory activity of the corpus luteum in hypophysectomised rabbits can be maintained by injection of gonadotropic hormones. It is possible, he believes, that in species in which abortion does not follow removal of the pituitary, the secretion of progesterin by the corpus luteum and/or placenta may be under the control of gonadotropic hormones produced by the uterine contents.

MENTAL HOSPITALS AND MENTAL HEALTH

In presenting the 123rd annual report of the Royal Edinburgh Hospital for Mental and Nervous Disorders last week Prof. D. K. Henderson said he regarded institutional psychiatry as perhaps the smallest part of the psychiatrist's task. He has a much bigger sphere which involves the prevention rather than the cure of those who may be nervously or mentally ill. The importance of this principle is well recognised by the managers of the hospital whose many organisations show that they are attempting to establish a mental health service in direct relation to the community. The clinics at the Royal Infirmary, at Jordanburn Hospital, and at the University Clinic have formed a chain of medical service which offers help and treatment to all ages and for all conditions of the nervous and mental

health. The number of patients treated shows a steady increase and people are no longer unwilling to consult a psychiatrist. The clinics are of great value in allowing medical students to become familiar with every phase of nervous and mental illness. The student is taught to learn to appreciate how emotional forces can control and modify bodily functions and how readjustment can be effected. The importance of this is emphasised by the fact that a recent survey of a group of insured patients under the National Health Insurance Act showed that a third were incapacitated as a result of nervous illness of some kind. Prof. Henderson said he looked forward hopefully to the time when a department for the treatment of early forms of nervous and mental diseases would be incorporated in every progressive general hospital.

At Glasgow, in the annual report of the Royal Mental Hospital, Dr. Angus MacNiven points out that nearly 40 per cent. of the total admissions show a depressive reaction. He deplors the lack of understanding among the public of mental disorders and mental hospitals, which he describes as a serious obstacle to progress. An encouraging feature, however, is that more than half of those admitted to the hospital came as voluntary patients, using the hospital for the treatment of their mental illness as they would a general hospital for the treatment of a physical complaint. A mental hospital is not a place of discipline, but should be regarded more as a refuge to the patient in time of trial. He stressed the importance of providing facilities for the treatment of functional nervous disorders. The Lansdowne Clinic provided an initial step in this direction, but many cases required to be removed from their home environment and there is an urgent need for the provision of a special hospital or a special department in one of the general hospitals for the treatment of functional nervous disorders.

THE TRAINING OF NURSES IN SCOTLAND

The report of the Scottish Departmental Committee on the Training of Nurses contains some important suggestions for the future development of the nursing profession in Scotland. After a brief summary of the functions of the General Nursing Council for Scotland, the committee review the essential requirements for a fully trained nurse, among which requirements they place experiences in the wards of a hospital for infectious diseases. They discuss the various interests involved—the nurses themselves, the public, the hospital, the doctor, and the local health authorities—showing that no scheme for the training and provision of nurses can be regarded as satisfactory which does not give due weight to the just requirements of each. They point out defects in the present system and make pertinent proposals for remedying them. The most important of the 15 recommendations summarised at the end of the report is that for the establishment of a "Central Registry" to contain the names of nurses who are "fully trained," that is, trained for five years, four of them being spent in a medical and surgical hospital and in a fever hospital, followed by two courses of six months each out of a selection offered, such as sick children, tuberculosis, mental, orthopædics, chronic sick. Nurses who are entitled to have their names on two parts of the register, one being the general part, would also, under the scheme, be eligible for inclusion in the "Central Register." Other recommendations include provision for the examinations in anatomy and physiology, hygiene, and dietetics of the Preliminary State Examination, to be taken as a normal procedure

before trainees enter hospital; grants to hospitals providing facilities for the training of nurses for the "Central Register" and also, in lesser amount, to hospitals training in the present system; the establishment of a supplementary part of the register for tuberculosis nurses; and the revision of arrangements for application between hospitals in order to secure a greater degree of elasticity.

PARIS

(FROM OUR OWN CORRESPONDENT)

THE NEW FRENCH ACADEMY OF SURGERY

THERE is nothing in France exactly equivalent to the F.R.C.S. Eng. with its searching examinations and enviable prestige. There is no special surgical diploma or *brevet de chirurgien*. A certain cachet attaches to membership of the *Syndicat des Chirurgiens*, or to one or other of the Parisian or provincial surgical societies, or the surgeon may secure election to the Academy of Medicine or the Academy of Sciences. But now the old *Académie de Chirurgie* has been resuscitated at the Sorbonne in the presence of Mr. Lebrun, President of the Republic, and many other notables. Prof. Gosset, who as president of the executive committee has taken a leading part in this revival, traced in his speech the history of the Academy from its birth in the reign of Louis XV. Dissolved during the French Revolution it has carried on since as little more than a surgical society, its members not enjoying the title of academician. It has long been felt as a slur on surgeons that the Academy of Medicine should monopolise academic honours in the profession; out of a total membership of 120, only 16 seats are reserved for surgeons, though it should be noted that the present occupant of the presidential chair is the well-known surgeon, Prof. Hartmann. It would have been a delicate task to reorganise the Academy of Medicine in such a way as to satisfy the legitimate claims of the surgeons, and Prof. Gosset is to be congratulated on his solution of the problem.

NEW IDENTITY CARDS

Steps have been taken to facilitate travel in France by the issue of a special identity card to be called the "tourist card," and to be valid for six months. It will be issued gratis by French consulates, and will help to do away with some of the formality which has hitherto embarrassed the foreigner wishing to pay something more than a flying visit. The period of grace, during which identity cards were superfluous, has till now lasted only two months and a week. After this interval, visitors had to apply to the préfet for a non-worker's card, for which there was something to pay. Under the new regulations the foreigner shows his passport, signs a declaration to the effect that he will not work in France, and that he has sufficient funds to support him during his stay. His tourist card he must give up on leaving France within six months; if he stays more than that he must apply and pay for a non-worker's card. Between now and the end of this year tourists who have not received a tourist card before entering France must apply for it within 15 days of entering French territory at the local prefecture of police.

PARIS TRAFFIC

In 1935 there were 237 traffic deaths in Paris itself and 226 in its suburbs. This total of 463

compares favourably with the corresponding figure (498) for the previous year. The victims per cent. were pedestrians 56, cyclists 20, employers of various other vehicles 23. Responsibility for the accidents was divided fairly equally between the killers and the killed, 52 against 46 per cent.; in only 2 per cent. was there uncertainty which of the parties was to blame. The danger was greatest late in the afternoon, as many as 141 of all the fatal accidents occurring between 5 and 8 P.M. There were only 30 fatal accidents between midnight and 6 A.M. In 19 per cent. the accidents were traced to drivers who were "insufficient masters of their speed."

CHARLES NICOLLE

The death of Charles Richet, man of science and man of letters, has now been followed, after only a

few weeks, at Tunis, by that of another Frenchman distinguished in the world of letters as well as in that of science. Charles Nicolle was gifted with a restlessly imaginative mind, and there was nothing he hated more than the humdrum orthodoxy of most so-called seats of learning. It was, therefore, perhaps well for him that he was able to spend most of his life after 1903 in Tunis where, far from faculties and universities and learned societies, he was free to scoff at them gently and to go his own way, in science as well as in letters. He was never attached to the Pasteur Institute of Paris, and the rumour that he would succeed Roux at this seat of learning proved to be ill-founded. As he remarked whimsically a few years ago, he had too much imagination and independence ever to become a conventional man of science.

CORRESPONDENCE

INTRANASAL SUBMUCOUS INJECTIONS OF CALCIUM

To the Editor of THE LANCET

SIR,—During experiments on the local effect of subcutaneous injection of salt solutions I observed¹ that repeated injection led to thickening of the subcutaneous tissue together with desquamation of the epidermis. The thickening is probably due to an increase of fibrous tissue (histological examinations have not yet been made), and I thought that, if the same effect could be produced by submucous injections, it might be of therapeutic value in cases where excessive serous secretion shows abnormal permeability of the vessels (e.g., vasomotor rhinitis and hay-fever). This idea gained support from a case in which I had made several submucous injections with novocain for the treatment of aural tinnitus²; there appeared such thickening of the submucous tissue and disappearance of the cavernous plexus of the inferior concha that further injections were impossible.

Since then, to patients with increased serous nasal secretion, I have given submucous injections of calcium salts into the inferior concha, hoping that the constricting effect of the calcium ions would considerably amplify the non-specific effect of the salt. At first I injected 5–10 c.cm. of 1.5 per cent. calcium chloride solution; later I used stronger solutions, but as calcium chloride in high concentration injures the tissues, I employed 10 or 20 per cent. Calcium Sandoz (gluconate) solution, which was always well tolerated. The injection is made with a straight needle, at least 5 cm. long, into the anterior part of the inferior concha. Very little pain is felt, and anaesthesia is therefore unnecessary. The needle is pushed in for 1.0–1.5 cm., parallel with the concha, and 5 c.cm. is injected, taking about thirty seconds. Only a slight swelling of the concha ensues, since the injection is mostly intravenous; indeed, this submucous route may be used instead of the ordinary intravenous one when the latter presents difficulty. During the injection there is a feeling of heat in the whole body, but no other side-effects and no pain, either at the time or later. When the needle has been pulled out, an adrenaline tampon is placed in the nose and pressed against the wound; after some minutes this can be removed. I repeat the injection on the third day and again on four or five occasions. Usually I do not inject both sides on the same day. In most cases the first injection is followed

by reaction with increased secretion, but after the later injections this was not observed. In the patients thus treated the secretion has diminished considerably, and in some cases I have a very good therapeutic result with complete disappearance of unpleasant hypersecretion. In those with allergic rhinitis (principally rhinitis aestivalis) the local application of calcium is active not only in its constricting effect, but probably also because, at high local concentrations of calcium, the antigen-antibody reaction passes off without irritation of cells—that is to say, without hypersecretion. This has lately been shown by P. Kallós and L. Kallós-Defner³ in my laboratory.

A detailed report will be published later. Here I want only to show this new possibility of effective therapy.—I am, Sir, yours faithfully,

ROBERT BÁRÁNY.

Upsala, Sweden, Feb. 29th.

"A DOUBTFUL CASE OF TYPHUS FEVER"

To the Editor of THE LANCET

SIR,—It seems to me that the best comment on the epithet "doubtful" as applied to the case of typhus fever reported on p. 864 of your issue of Oct. 12th last is to be found in the following extracts taken from the article on typhus fever by Drs. Brill and Baehr in vol. i. of Nelson's "Loose-Leaf Living Medicine":—

(P. 200): "The difficulty in diagnosis is increased, when a sporadic case of the endemic variety is encountered. However if one bears in mind the important clinical features of the disease . . . mistakes in diagnosis will rarely be made. If an incorrect diagnosis is made, it may easily be corrected when the critical fall in temperature occurs, as the crisis is one of the most important differential features of the disease."

"Weil-Felix reaction . . . A negative test cannot be accepted as evidence that the disease is not typhus fever."

(P. 201): "The authors' experience is that in cases of the endemic type the serum seldom gives a W.-F. reaction in dilutions sufficiently high to be of diagnostic value."

" . . . The Widal agglutination test with typhoid bacilli was found to be of little differential value. Typhus patients who had previously had typhoid fever . . . often developed a positive Widal reaction during the second week of their disease."

To my mind the case reported is a typical instance of the sporadic endemic typhus, which is a severe

¹ Deut. med. Woch., 1932, lxxviii., 1560.

² Bárány, R.: Acta oto-laryng., 1935, xxiii., 201.

³ Klin. Woch., 1935, xiv., 1247. For further information, cf. Wojatschek, W., Undrits, V. F., and Drennowa, K. A.: Zeits. f. Hals-, Nasen-, u. Ohren-, 1933, xxxiii., 191; and Drennowa, K. A.: Arch. f. Ohren-, Nasen-, u. Kehlkopf., 1930, cxxx., 235.

but seldom fatal illness. As Dr. Brill says in the article above quoted (p. 201) referring to the tradition in text-books which inclines the student to believe that there is any difficulty in separating the two diseases (typhus and enteric): "the two diseases have nothing in common in pathology, etiology or symptomatology."

Incidentally, were the two laboratories to which the blood-serum was sent stocked with the varieties of *Bacillus proteus* isolated by the Federated Malay States Institute for Medical Research (see their Bulletin No. 1 of 1930)? It is difficult to say what value can be placed on their reports "Weil-Felix reaction, negative" on a patient who brought the disease from the Straits, if they do not report that the serum was tested against strains of *B. proteus* appropriate to the case in question. If the Port of London health authority reports typhus only when confirmatory evidence is supplied by a laboratory we should hear more about this, and in a disease like typhus it is no use hedging and saying that "bacteriologically the case was considered to be typhoid"!

I am, Sir, yours faithfully,

Hankow, Jan. 27th

A. H. SKINNER.

THE TREATMENT OF VAGINAL DISCHARGE

To the Editor of THE LANCET

SIR,—I read Mr. Gordon Luker's letter in your last issue with great interest, inasmuch as his experiences differ so widely from my own. After eight years' work in a large clinic, I have come to the conclusion that the majority of non-venereal discharges of which women complain is due either to a staphylococcal or, more frequently, to a trichomonas infection of the vagina. In a small series of 30 cases which I investigated some time ago, I found the trichomonas—identified by the dark-ground method—in 14, or nearly 50 per cent. Its presence was in 9 cases diagnosed before microscopy by the typical frothy discharge. This afternoon I examined the first 6 cases that came in, and found trichomonas in 2 of them. Advertisement or no, this form of infection has yielded more rapidly to Devegan than to any previous form of treatment that I have tried, and while not for an instant suggesting the application of the remedy to vaginal discharges in general, I have found it very useful for what, in my experience, is a common infection.

I am in complete agreement with Mr. Luker on the necessity for a thorough examination of the patient and the discharge itself, but I must differ from him in his opinion of the relative frequency of a trichomonas infection, and the efficacy of devegan in its treatment. I am, Sir, yours faithfully,

Harley-street, W., March 2nd.

KEITH DUFF.

"NEAR" X RAY THERAPY

To the Editor of THE LANCET

SIR,—Consideration of the possibilities of Chaoul's new "near" X ray therapy method (THE LANCET, Feb. 29th, p. 482) suggests that these are not limited to the special low-voltage short-focus tube, but could be extended to a much wider use with any fully shock-proof X ray therapy tube. Indeed, many of Chaoul's best results have been attained with a kilovoltage of 180, with 0.5 mm. Cu. filter at 8 cm. distance, or with 100 kV., 0.5 mm. Cu., 11 cm. distance (see Tables C and B in *Strahlentherapie* 1933, xlviii., 31 (21 cases)). Tests with a 200 kV. shock-proof tube have shown that it gives a radiation of 50 r/min. at 100 kV. and 30 cm. distance, 0.2 mm. Cu. equivalent filter. Approximately at 15 cm. the radiation is

200 r/min., and at 7.5 cm. it is 800 r/min. Treatment at 6 cm. seems possible with this tube. I doubt if such extremely high intensities as 800 r/min. or more have ever been applied to patients: they would correspond to that from one curie in a bead-sized light applicator to rodent ulcers of minute size by Kelly and Burnham for one minute at the end of a long rod.

After tests of the tube's emission at from 1 to 6 M.A. from 60 to 100 kV. (0.2 mm. Cu. filter) and from 1 to 4 M.A. from 100 to 200 kV. (with heavier filters) I have treated several patients with ulcerated breasts (primary or recurrent) and a supraclavicular metastasis from a parotid tumour. The factors used were 12 and 15 cm. distance, 70 or 80 kV., 4 M.A., and 0.2 mm. Cu. filter; 1½ and 2 minutes exposure. Tests with surgical specula for mouth, tonsil, and cervical applications have also been made with ionisation and pastille methods. Lead or lead-rubber to localise the fields has appeared adequate; special applicators could be put on the market for various sizes and distances.

The daily treatments of from one to four minutes contrast agreeably with the opposite pole of method, the protracted-fractional of Coutard. The latter appears to act "selectively," powerfully affecting abnormal and sparing normal tissues (as radium distance applications do) and is thus most valuable for deep-lying tumours in vital areas; whereas the near method appears to act more "cytocaustically"—as near or contact radium applications (gamma or beta) act—thus being more suitable for quite superficial lesions, specially if already ulcerated. These two extremes of method have greatly enlarged the field of X ray therapy. The near method, however, should be explored to the full possibilities of shock-proof tubes and not be limited to the use of the small aperture 60 kV. tube specially designed for cavity applications.—I am, Sir, yours faithfully,

J. H. DOUGLAS WEBSTER.

Harley-street, W., Feb. 29th.

ALLEGED NEGLIGENCE IN HYPODERMIC INJECTION

To the Editor of THE LANCET

SIR,—The article in last week's issue of THE LANCET (Medicine and the Law, p. 500) reminds me of an unpleasant experience I suffered about 25 years ago. I have before now related the circumstance to my students as a warning.

About five years prior to the incident leading to the allegation I had been consulted by a practitioner of medicine who had contracted syphilis, and I had treated him over a long period. One evening a telephone message summoned me to his house some four miles distant. He was suffering intense pain. Obviously morphine was necessary, but upon my suggestion that I should go home and fetch a syringe and drug he replied, "It will take you half an hour" (20 mile limit then). "I can't stand this pain. Here is my syringe and morphine."

Upon examination of the syringe I noticed that it was fitted with a leather washer and remarked that it could not be boiled. He persuaded me to use it; after rinsing it many times in carbolic acid solution, morphine was dissolved in boiled water and injected into the arm. Three or four days later I heard that the doctor was in a home, and on going to see him learnt that he had cellulitis of the arm which needed incisions. I expressed regret. The following day a letter informed me that he was taking proceedings against me, claiming damages for negligence. On

approaching the defence society to which I subscribed I learnt that the plaintiff had already communicated with the society, and the secretary doubted whether in the circumstances the committee of the society would arrange for my defence, because I should lose. In answer to the question "Why," he said that in cross-examination the counsel would ask me whether I had found fault with the syringe, and upon my admitting that I had he would say, then you had no right to use it. A mutual friend approached the practitioner. Years later it came to my ears that he had used the argument that the counsel for the defence would have asserted that in a normal man cellulitis would have not developed, and that the plaintiff's resistance had been reduced by syphilis. Anyway the charge was withdrawn; a few days later a generous patient made me a present which I had the pleasure of forwarding to the unfortunate practitioner, and this more than covered his expenses.

I am, Sir, yours faithfully,

O. L.

March 2nd.

STAMMERING

To the Editor of THE LANCET

SIR,—I was very interested in the annotation on the subject of stammering in your issue of Jan. 25th (p. 208) but I was puzzled by the following sentence: "For this reason some authorities have dispensed with any specific speech training and have concentrated . . . on relaxation." Since we are not bivocal but use the larynx for speech and song, surely speech training should proceed on the lines of training the voice for song. All singers will agree that one of the most important factors in voice training is to teach the pupil to relax as far as possible all muscles in the throat and neck which do not assist in the production of vocal tone; in other words, to overcome hypertonicity which must be overcome not only by a stammerer but by every speaker or singer who aims at getting the best results from his larynx.

Miss Kate Emil-Behnke in her interesting letter of Feb. 22nd seems to contradict herself when she says, "it will yield to psychic handling combined with 'relaxing' and quiet breathing exercises," and "the serious error of adopting *elocutionary* treatment." If elocution means, as it should, speech training and voice training, it must include some study of deep breathing (to learn breath control) and "relaxing" as described above. If Miss Behnke means the type of elocution which merely consists in the overstressing of the consonants I am in agreement with her, because nearly all stammerers already overstress the consonants at the expense of the vowels, and thus talk in the jerky, staccato manner which, in its most exaggerated form, is a typical stammer. When singing the vowels must predominate, and they should do so to some extent in good speech. It is this predominance of the vowels which enables the stammerer to sing without difficulty. If the stammerer will cultivate a slight predominance of vowels over consonants he will learn to speak smoothly and will overcome hypertonicity. This should be the aim of everyone who wishes to speak musically and audibly; it is not a mannerism to cure a stammer but the method of getting the best results with the least effort.

Although some knowledge of deep breathing and breath control is needed for perfect speech it should be clearly understood that taking a deep breath before speaking will increase the difficulties of a stammerer and of any other speaker. "Little and often" is a good rule. One of the greatest singers

of all time said, "Never take more breath than can be easily controlled."

The unusual type of stammerer who stammers on the vowels as well as "sticking" on the consonants presents a difficult problem to the speech therapist, but space will not allow a detailed explanation here.

The variability of the incidence of a stammer proves that it is very largely due to a neuropathic condition, but I cannot think of anything more calculated to overcome this condition than learning the fundamental principles of perfect speech, while the success which follows such study will obviously allay anxiety.

I am, Sir, yours faithfully,

H. ST. JOHN RUMSEY, M.A.,

Instructor for Speech Defects at Guy's Hospital.

Feb. 22nd.

A SECONDARY REACTION AFTER ANTI-CHOLERA INOCULATION

To the Editor of THE LANCET

SIR,—During the last cholera epidemic in the Bassi district in Patiala State mass anticholera prophylactic inoculation was done. This produced a general and a local reaction which lasted for two or three days after the inoculations. To my utter surprise, however, about 8–10 per cent. of the persons inoculated got another general and local reaction on the twelfth, thirteenth, or fourteenth day after the inoculation, in the usual form of a pyrexia (varying from 100–102° F.) and local redness at the site of the injection, along with pain and tenderness. But this secondary reaction, as I may call it, was milder than the primary one, and no other sign or symptoms were observed. It lasted for about 28–36 hours only, and many of the sturdy villagers took no account of it. Those who came to us for advice were treated on general lines and symptomatically.

The only explanation that I could think of at that time was that the condition was caused by abscess formation due to negligence in our asepsis. But among 4000 cases of inoculation done by me in that part of the district, there was only one abscess (on the sixth day). We had taken every possible aseptic precaution throughout and the vaccine, which was supplied by the Central Research Institute, Kasauli, was used within two or three days of its receipt. I consulted my colleagues who too were working in the other cholera-stricken areas of the State and all of them had also observed the same phenomenon. We could find no published information, however, concerning the cause or significance of a secondary reaction after prophylactic anti-cholera inoculation, and I should be glad therefore if any of your readers could tell me whether they have seen such a thing or can throw light on its origin.

I am, Sir, yours faithfully,

M. TEWARI,

Hon. Clinical Assistant, Rajindra Hospital,
Patiala (State), India.

Jan. 15th.

AN ADDRESS IN HARLEY STREET

To the Editor of THE LANCET

SIR,—A distinguished hospital surgeon, not living in Harley Street, told me the following story; it is very apropos to Mr. F. C. Goodall's letter in your columns last week. The surgeon was asked to see in consultation a patient living in the country, when it was his duty to tell the husband "there is nothing to be done." Leaving the house with the family practitioner, the latter was called back by the husband, and on rejoining the consultant he exclaimed,

Surgery Inspection

A practitioner who recently applied for inclusion in the London medical list intimated that he desired to carry on an insurance medical practice at a place other than where he resided, the distance between the addresses being about a quarter of a mile. There was no caretaker at the surgery, no deputy had been appointed to act in case of emergency, and there was no telephone either at the residence or at the surgery. The doctor said he proposed to exhibit at the surgery a notice indicating his private address. The insurance committee, not being satisfied that the proposed arrangements were adequate, asked an ex-chairman of the committee, along with the secretary of the local medical and panel committee, to visit the surgery and report. On the morning on which the visit was due to be made a letter was received from the doctor to the effect that his surgery premises were shortly to be demolished, that he was hoping to obtain other premises in the course of a few weeks, and suggesting that in these circumstances the visit was unnecessary. It was then too late to cancel the visit and the report showed that the waiting- and consulting-room consisted of a small shop with a screen running partially down the centre. The

screen did not reach from end to end of the room nor did it reach the ceiling, there being at least three feet between the end of the screen and the further wall and a similar gap between the top of the screen and the ceiling, so that a waiting patient could hear all that occurred in the consulting-room. The committee's representatives informed the doctor that the accommodation provided was unsuitable for an insurance medical practice; his application for the inclusion of his name in the medical list remains in abeyance pending the submission of particulars about alternative accommodation. Some other premises have recently been found unsuitable for their purpose. Up to the present time visits have been paid to surgeries only when practitioners have applied for consent to the employment of an assistant or where some special cause has arisen. The insurance committee has now referred it to the proper subcommittees to consider and report on the desirability of satisfying the committee in every instance with the surgery accommodation to be provided by an insurance practitioner before he undertakes insurance work. Clause 9 (4) of the Terms of Service lays on the insurance committee the onus of seeing that the accommodation provided befits the conditions of practice.

OBITUARY

JAMES BRUNTON BLAIKIE, M.B. Edin. [R]

Dr. James Blaikie, who died on Feb. 26th, received his medical education at the University of Edinburgh where he was a successful student and president of the Royal Medical Society. He graduated as M.B., C.M. in 1896 and proceeded to the M.D. degree in 1903, and acted as resident physician at the Royal Infirmary. In London he held clinical appointments at the Hospital for Sick Children, the Victoria Hospital for Children, and the Hospital for Skin Diseases, Blackfriars. He was appointed physician to the Hospital for Consumption in Margaret-street, and was assiduous in attendance there, his professional work being of a practical order. He made occasional contributions to the *Edinburgh Medical Journal* and to these columns, but his time was absorbed in an extensive practice. He was held in high esteem by his colleagues and a large section of the public, as was evidenced by the attendance at the service held in his memory. He had the gift of making friends of his patients, and in particular earned the gratitude of the mothers whose children he had under his care. Such holidays as he spared himself were spent in fishing, a sport to which he was devoted and about which he wrote pleasantly.

SEPTIMUS TRISTRAM PRUEN, M.D. Durh.

THE death occurred on Feb. 19th of Dr. Septimus Pruen, for many years a prominent practitioner in Cheltenham. He was born at Clifton, Bristol, in 1859, the son of Dr. William Ashmead Pruen, received his education at Bedford School, proceeding for medical training to St. Bartholomew's Hospital and the University of Durham. He graduated as M.B. Durh. in 1883 with honours and was a medallist for his public health work; in the following year he took the diploma of M.R.C.S. Eng. He was appointed assistant demonstrator in anatomy and physiology at Durham and later acted as house surgeon to the Cheltenham Hospital. This post he held for two years and in 1886 proceeded to Central Africa as a medical

officer of the Church Missionary Society. He remained in Africa for three years and recorded his experiences in a short work "Arab and the African." On his return to England he commenced practice in Cheltenham and became medical officer at the Cheltenham Medical Workhouse and Provident Dispensary, and surgeon to the Hospital for Sick Children. About this time the open-air treatment of phthisis was being introduced into this country by Otto Walther's pupils and Dr. Pruen collaborated with his partner, Dr. J. C. Braine-Hartnell in founding the Cotswold Sanatorium on the hill 600 feet above the town. The venture was popular and successful, and for many years there was a considerable publication of useful papers dealing with various aspects of hygienic-dietetic treatment. Dr. Pruen was local medical officer of the Charity Organisation Society and was an energetic member of the British Medical Association of which he was a member for 44 years, being local secretary at the Cheltenham meeting in 1901 and later president of the Gloucestershire branch of the Association.

VINCENT THOMAS BORTHWICK YULE, M.B., Ch.B., D.P.H. Aberd.

THE death occurred on Feb. 17th of Dr. Vincent Yule, the M.O.H. for the borough of Peterhead. He was born in Peterhead and had a successful career at the University of Aberdeen, where he graduated as M.A. and took the medical degrees of M.B., Ch.B. in 1917 and D.P.H. in 1920. During the war he received a commission as Captain R.A.M.C., and saw service in East Africa. At the conclusion of hostilities he was appointed R.M.O. at the Aberdeen City Hospital, after which he accepted an appointment in Mexico as medical officer to one of the oilfields. On his return he was for three years in practice at Maud, Aberdeenshire, when he entered on practice at Peterhead and in 1925 was appointed M.O.H. for the borough, a position which he held at the time of his death. This occurred at the age of 45 after a short life of full and varied experience.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Milk and Nutrition Problem

ON March 2nd in the House of Commons Mr. RAMSBOTHAM, Parliamentary Secretary to the Ministry of Agriculture, moved the third reading of the Milk (Extension of Temporary Provisions) Bill.

Mr. T. JOHNSTON, in moving the rejection of the Bill, said that since the previous discussions on the measure in the House of Commons there had been a remarkable correspondence in the *Times* on the subject of insufficient nutrition among the population of this country. Nobody in that correspondence denied that at least 10 per cent. of the population was living below the British Medical Association's minimum standard. Sir John Orr had said that almost one-half of the population in our industrial areas were not getting enough to eat, and he mentioned milk as one of the foodstuffs which ought to be better and more widely distributed. The Minister of Agriculture did not deny that a large proportion of the population was under-nourished, and yet the right hon. gentleman was using public money for the destruction of 27 per cent. of liquid milk through its diversion to manufacturing purposes. We were spending at least £111,000,000 a year in the treatment of disease and the policy of organising scarcity in such an essential foodstuff as liquid milk was against the public interest.

Mr. ELLIOT, Minister of Agriculture, in reply, said that the enormous importance of fresh food such as milk in the avoidance of disease was a matter of general agreement in the House. His only point of difference with Mr. Johnston was when the right hon. gentleman said that the Government were organising scarcity. The production and consumption of milk had increased greatly in recent years. Mr. Johnston's motion, if carried, would bring the milk in schools scheme to an end. Steps were outlined in this Bill to extend the supply of milk itself, as well as that of butter and cheese.

Mr. JOHNSTON asked whether raising the price of milk to children's hospitals and to poor-law infirmaries was doing anything to increase consumption.

Mr. ELLIOT called on Mr. Johnston to mention one child in one hospital who had received a pint of milk less because of the steps taken by the Milk Marketing Board.

Mr. JOHNSTON asked whether the Minister of Agriculture was aware that a hospital in Glasgow had to pay £500 a year more for its milk, and that there were threats by the managers of some hospitals that they would be compelled to take a lower grade of milk.

Mr. ELLIOT: I challenged the right hon. gentleman to name one hospital where one child was having one pint of milk less per day and he is totally unable to do so. He merely said that in future in some hospital a lower grade of milk may be used. I do not think he has met the challenge. If the whole assistance being devoted to the butter and cheese industry were devoted to the liquid milk industry it would not mean a reduction of more than a quarter of one farthing a pint in the price of liquid milk, and no one would say that this would increase the consumption of liquid milk to-day. The right hon. gentleman went on to say that the Government had given a breathing space to the industry for which they made no apology, and they had given cheap milk to schools, for which they did not apologise, and this was a Bill to continue those things.

Mr. T. WILLIAMS said that nothing in this Bill was calculated to provide more milk for that section of the community which most needed it.

The motion for rejection was negatived by 242 votes to 110, and the Bill was read the third time.

Voluntary Hospitals (Paying Patients) Bill

In the House of Commons on Thursday, Feb. 27th, the Voluntary Hospitals (Paying Patients) Bill was read a second time.

HOUSE OF COMMONS

WEDNESDAY, FEB. 26TH

Newspaper Wrappers and Food Contamination

Mr. H. G. WILLIAMS asked the Minister of Health if he was aware of the practice among retail butchers and fishmongers of purchasing old newspapers, which might be contaminated and carriers of disease, for the purpose of wrapping up meat or fish sold in retail shops; and whether he would take steps to make this practice illegal, and ensure the use of clean grease-proof paper for these purposes.—Mr. SHAKESPEARE replied: My right hon. friend is aware of this practice, which on general grounds of cleanliness is to be deprecated, but he is advised that there is no definite evidence that the wrapping of meat or fish in newspapers is a factor in the spread of disease, and he would not therefore be justified in taking the steps suggested by my hon. friend.

Medical Services at Junior Instruction Centres

Mr. TEMPLE MORRIS asked the Minister of Labour whether medical inspection and treatment was now available for boys and young men attending instructional centres in the special areas; and, in that case, by whom the cost was provided.—Mr. ERNEST BROWN replied: I assume that my hon. friend is referring to persons in attendance at junior instruction centres and not to adults. Proposals submitted by education authorities for the establishment and conduct of authorised courses of instruction, including junior instruction centres, may include provisions under which any boy or girl may be referred by the superintendent of the course to the school medical officer, with a view to such inspection, and, in England and Wales, such treatment as may be found desirable. I have approved proposals including provisions—of varying extent—for medical services from the following authorities in the special areas: education authorities for the administrative counties of Durham, Northumberland, Glamorgan, Monmouth, Ayrshire, Dunbarton, and from the education authorities for the county boroughs of Gateshead, South Shields, Sunderland, and Merthyr Tydfil. I intend, at an early date, to issue to all authorities conducting authorised courses of instruction a memorandum dealing with the provision of medical services in connexion with junior instruction centres, and it is my hope that this will lead to a marked increase in the number and scope of proposals of this kind.

THURSDAY, FEB. 27TH

Provision of Food at Junior Instruction Centres

Mr. GEORGE HALL asked the Minister of Labour whether he was aware that an examination by the school medical officers revealed that 57 per cent. of the trainees at four junior instruction centres in the county of Glamorgan were suffering from malnutrition; and whether he would take steps to empower the local authorities responsible for these centres to supply meals as well as milk to trainees in attendance.—Mr. ERNEST BROWN replied: Local education authorities have no power to provide ordinary meals in junior instruction centres. Free milk is, however, being provided in the Glamorgan centres, and I am informed that the school medical officer expressed the view that since any food given at the junior instruction centres can only be a casual and temporary addition to the diet of the pupils, the milk available is more useful than any other food which could be suggested in the circumstances. I am, however, making inquiries into the adequacy of the existing arrangements.

Certification of Cases of Silicosis

Mr. LEACH asked the Home Secretary if he would consider introducing further legislation to ensure prompter

and easier certification of cases of silicosis in the mining and quarrying industry, and to ensure that compensation and measures for the recovery of the victims might be made more certain.—Sir JOHN SIMON replied: I would refer the hon. Member to the reply given on the 13th of this month. If the hon. Member will be good enough to send me a statement showing where and how it is suggested that the medical arrangements and the procedure under the Silicosis Schemes could be improved, I shall be happy to consider it.

Mr. LEACH: Does not the right hon. gentleman agree that both the law and the regulations operate very harshly towards these poor fellows?—Sir J. SIMON: It is a very complicated subject, but I have the fullest sympathy with those who want to have the whole situation cleared up and made as simple as possible.

Death Certifications and Vaccination

Mr. BANFIELD asked the Minister of Health how many of the deaths associated with vaccination on certificates of deaths in the years 1933, 1934, and 1935, respectively, were or would be classified by the Registrar-General to vaccinia; and how many deaths under five and over five years of age, respectively, were or would be classified as chicken-pox and erysipelas during the years in question.—Sir KINGSLEY WOOD replied: The following is the statement:—

Year.	Deaths associated with vaccination and classified to vaccinia.	Deaths classified to—			
		Chicken-pox.		Erysipelas.	
		Under 5 years.	Over 5 years.	Under 5 years.	Over 5 years.
1933	3	31	12	296	895
1934	5	36	10	231	1227
1935	4	Not yet available.			

Public Health Legislation

Sir ARNOLD WILSON asked the Minister of Health whether and, if so, when he proposed to introduce a Public Health Amendment Bill which would embody in that general law and make generally applicable powers usually granted by Parliament as a matter of course in local Acts, as recommended by the Select Committee on Private Bills in 1930 for reference to a joint committee of both Houses, in the same way as Consolidation Bills.—Sir KINGSLEY WOOD replied: My hon. friend will be aware that a draft has been published of a Bill to consolidate with amendments part of the general public health law. In preparing this Bill account has been taken of the relevant provisions allowed by Parliament in local legislation. I regret that considerations of parliamentary time have rendered it impracticable fully to implement the recommendation to which my hon. friend refers, but I recognise its importance and hope it may be practicable to take further action in an early session.

Unemployed Persons and Food-supplies

Mr. DAVID ADAMS asked the Minister of Health whether, in view of the fact that the consumption by families of the unemployed of meat, including beef, mutton, bacon, &c., and of eggs, was, like that of milk, only about one-third that of the average of the whole country, he would take the necessary steps, as in the case of milk, to ensure cheaper supplies to unemployed of these essential food-stuffs, and thus raise the low nutritional standards of these citizens.—Sir KINGSLEY WOOD replied: The consumption of the commodities mentioned as well as of other foodstuffs by various classes of the community is a matter which receives the constant attention of my Advisory Committee on Nutrition, but the most effective steps that can be taken to raise nutritional standards are undoubtedly such steps as are being taken by the Government to reduce unemployment and increase purchasing power.

Tuberculosis in Wales

Sir WILLIAM JENKINS asked the Minister of Health what number per thousand of the population of Wales

were suffering from tuberculosis; what number under treatment at sanatoria or other suitable institutions; what number of recoveries; and what number of deaths under 12 years of age, under 20 years, under 30 years and over for the years 1924, 1926, 1930, 1934, and 1935 giving the figures separately for each county in Wales.—Sir KINGSLEY WOOD replied: As regards the first three parts of the question, the following are the figures for which the hon. Member asks, according to the returns furnished by the local authorities and the King Edward VII Welsh National Memorial Association to the Welsh Board of Health in respect of the year 1934:—

Tuberculous persons on the registers of medical officers of health at Dec. 31st, 1934, per thousand of the population of Wales	9'64
Under treatment or observation at sanatoria or other suitable residential institutions on Dec. 31st, 1934 ..	1650
Number of recoveries recorded during 1934	1213

As regards the fourth part of the question, figures are not available for the age-groups specified. The available figures of tuberculosis deaths by ages in the 13 Welsh counties are published in the Registrar-General's Statistical Review, Tables, Part I., Medical, Table 20 for the years 1924, 1926, and 1930, and Table 24 for 1934. Figures for 1935 are not yet available.

MONDAY, MARCH 2ND

Expectation of Life of War Pensioners

Mr. MABANE asked the Minister of Pensions if, for the purpose of his estimates, the expectation of life of war pensioners was calculated according to a normal table or on a table which gave to war pensioners an expectation of life shorter than the normal.—Mr. R. S. HUDSON replied: The mortality-rate of disabled pensioners is and will for some years to come be greater than the normal, and in framing the Estimates of the Ministry of Pensions this and all other relevant factors are taken into account.

Convictions for Murder

Mr. DAY asked the Home Secretary the number of persons convicted of murder and sentenced to death for the five years ended to the last convenient date; the number reprieved; the number of sentences quashed on appeal; the number of persons certified as insane and removed to Broadmoor; and the number so convicted that were recommended to mercy by the jury, and with what result.—Sir JOHN SIMON replied: The particulars are as follows:—

Year.	Persons convicted of murder and sentenced to death.	Reprieved.	Sentences quashed on appeal.	Certified insane and removed to Broadmoor.	Recommended to mercy.	
					No.	Result.
1931 ..	18	7	1	1	4	All reprieved.
1932 ..	15	6	0	0	5	3 reprieved. 2 executed.
1933 ..	19	9	0	0	10	9 reprieved. 3 executed.
1934 ..	24	12	2	1	12	6 reprieved. 1 executed. 1 conviction quashed on appeal.
1935 ..	21	8	2	1	8	1 conviction quashed on appeal.
Total for five years 1931-35	97	42	5	3	39	32 reprieved. 6 executed. 1 conviction quashed on appeal.

Imported Chilled Meat and Foot-and-Mouth Disease

Brig.-General CLIFTON BROWN asked the Minister of Agriculture whether, in view of the fact that the virus of foot-and-mouth disease survived in chilled meat and that this disease was distributed by the use of bones imported in chilled meat, the Government was taking any action to prevent the importation of meat which

might carry the virus from any country in which this disease prevailed.—Mr. ELLIOT replied: So far as I am aware, there is no evidence to support my hon. friend's statement that foot and mouth disease is distributed by the use of bones imported in chilled meat, but I recognise that there is some such risk. Regulations governing the exportation of carcasses to this country have been in force in the South American meat exporting countries since 1928 and assurances were given as recently as last year by the Governments concerned that these regulations are being properly enforced. In addition, orders are in force in this country directed to preventing the spread of disease through pig food and meat wrappers and other similar material.

Small-pox Deaths

Mr. BROMFIELD asked the Minister of Health, in view of the fact that the published reports of his department did not supply full statistics as to the numbers of vaccinated and unvaccinated cases of, and deaths from, small-pox which occurred in England and Wales during the years 1922 to 1934, he would supply a statement in respect of each of the years in question, showing, so far as possible, the cases and deaths which were recorded in the hospital registers as vaccinated, unvaccinated, and doubtful, respectively.—Sir KINGSLEY WOOD replied: I regret that I have no fuller information in respect of the years 1922 to 1933 than that contained in the annual reports of the Chief Medical Officer of my department. The appended table gives the vaccinal condition of cases of small-pox occurring in England and Wales in the year 1934 in towns of 150,000 population and over.

A. = Successfully vaccinated. B. = Unvaccinated.

Ages.	Vaccinal condition at time of infection.*		Ages.	Vaccinal condition at time of infection.*	
	A.	B.		A.	B.
Under 1 year	1	14 years	..	6
1 year	15	15 "	..	26†

* There were no doubtful cases.

† Including one fatal case in a youth of 16 years.

Smokeless Fuel and Atmospheric Purity

Mr. DAVID ADAMS asked the First Commissioner of Works, in view of the recent report upon atmospheric pollution issued by the Department of Industrial and Scientific Research which showed that the general cleanliness of the atmosphere was not improving, if he would give a lead to the country by ordering the use of smokeless fuel in the Government buildings under his department in London.—Mr. ORMSBY-GORE replied: Smokeless fuel is already used in Government offices whenever local circumstances make it possible without an unreasonable increase in cost.

TUESDAY, MARCH 3RD

Mental Deficiency Research

Mrs. TATE asked the Minister of Health how many local authorities had made use of their powers under the Mental Treatment Act, 1930, to provide money for research into mental disorder and deficiency; and how much money they had provided.—Mr. SHAKESPEARE replied: Owing to financial considerations, schemes have not yet been initiated under the specific provisions referred to; but the most recent record of the varied and extensive research work proceeding in public mental hospitals and mental deficiency institutions will be found in Part II. of the Board of Control's Report for 1934.

Army Recruits and Defective Health

The Duchess of ATHOLL asked the Secretary of State for War the proportion of men applying to join the Army in the last three years who were rejected for defective health or physique.—Mr. DUFF COOPER replied: The percentage of men served with notice papers who were rejected for medical or physical reasons during the three years ending Sept. 30th, 1933-35, was 52, 46, and 33 respectively.

School Dental Service

Mr. DAY asked the President of the Board of Education the number of children attending public elementary schools in England and Wales in the 12 months ended to the last convenient date who were inspected by school dentists; the number who were found to require treatment; and the number who received treatment under the arrangements made by local education authorities.—Mr. OLIVER STANLEY replied: Complete information is not yet available for the year 1935. The figures for the year ended Dec. 31st, 1934, are as follows:—

Children inspected	3,302,838
Found to require treatment	2,273,508
Treated	1,431,775

FOTHERGILL TESTIMONIAL FUND

THE following is the third list of subscriptions to the testimonial to Dr. E. Rowland Fothergill, received in response to the letter published in the *British Medical Journal* and *The Lancet* of Jan. 18th.

Amount previously acknowledged, £386 7s.

A. M. Daldy (Hove), £1 1s.; A. C. Gemmell (Hove), C. G. Schurr (Hove), L. A. Parry (Hove), A. Hall, F. H. Lawson (Hove), R. Ashleigh Glegg (Lewes), J. G. Thwaites (Brighton), G. B. Thwaites (Brighton), E. V. Oulton (Hove), I. Turton (Hove), D. A. Crow (Hove), Lillias M. Jeffries (Hove), Barbara M. Logan (Hove), Florence M. Edmonds (Hove), M. J. Oliver (Hove), A. N. Pollock (Hove), Robert Sanderson (North Lancing), Gladys M. Wauchope (Hove), Conwy L. Morgan (Hastings), F. J. Thorne (Bexhill-on-Sea), P. Lazarus-Barlow (Bexhill-on-Sea), R. Jaques (Worthing), Dr. Martin, Dorothea A. Carew Hunt (Hove), R. C. McQueen (Eastbourne), J. M. Anderson (Hove), J. T. Calvert (Eastbourne), A. G. K. Ledger (Shoreham), M. Ross Taylor (Eastbourne), Eliot Curwen (Hove), A. Burn (Eastbourne), P. S. Eves (Brighton), Duncan D. Macintosh (Worthing), Mark Jackson (Bexhill-on-Sea), and G. Tolcher Eccles (Hove), £60; H. F. Wattford (Newcastle) and G. R. Fortune (Newcastle), each 10s. 6d.; R. Boyd (Manchester), £1 1s.; Northumberland Local Medical Committee, £26 5s.; Derby Local Medical and Panel Committee, £5; Stockport and Leicester Local Medical and Panel Committees, and Sir Robert Bolam (Newcastle), each £5 5s.; A. Gregory (Manchester), F. L. Anglor (Wigan), T. H. Gardner (London), J. N. Ferguson (York), J. W. King (Derby), E. W. Goodall (London), and F. J. Baildon (Southport), each £1 1s.; W. Johnson Smyth (Bournemouth), £3 3s.; A. B. Murray (Banff), £5 5s.; Jane L. K. Aitken (London), 10s. 6d.; G. J. Awburn (Mottram, Manchester), John Clay (Newcastle), M. W. Renton (Dartford), and C. E. Douglas (St. Andrews), each £1 1s.; Nottinghamshire Panel Committee, £10 10s.; A. R. Berrie (London) and D. Clow (Cheltenham), each £1 1s.; Huntingdonshire Panel Committee, £2 2s.; J. E. Hailstone (Slindon Common, near Arundel), R. S. Harper (Hove), A. H. Williams (Horsham), W. Broadbent (Hove), H. Herbert (Worthing), E. R. Hunt (Hove), Alice Owen (Horsham), F. H. Allfrey (Southwick), W. G. Thwaites (Brighton), G. Handcock (Hove), T. S. Taylor (Hailsham), W. L. Dickson (Brighton), I. Kinsley (Brighton), East Kent Division B.M.A., F. E. Feilden (Hove), H. J. McCurric (Hove), John Kerr (Bexhill-on-Sea), and J. F. Atkins (Hove), £55; West Riding of Yorkshire Panel Committee, £10 10s.; Bath Division B.M.A., £20; Darlington Panel Committee, £2 2s.; Kent Panel Committee, £100; E. Lewis Lilley (Leicester), £1 1s.; Sheffield Panel Committee, £25; Shropshire Local Medical and Panel Committee, £10; R. G. McGowan (Manchester), £2 2s.; East Sussex Medical Committee, £210. Total £967 8s. 6d.

Cheques should be made payable to the Fothergill Testimonial Fund, and addressed to the treasurer, Fothergill Testimonial Fund, British Medical Association, B.M.A. House, Tavistock-square, London, W.C.1.

ROYAL SURREY COUNTY HOSPITAL.—At present this hospital is run at a loss of £2500 per annum and two new wards are being added to cope with the long waiting-list. To maintain these and the nurses' home an additional income of about £4000 will have to be obtained. This means that in all an additional yearly income of £6500 or £7000 must be found if the hospital is to be clear of debt.

MEDICAL NEWS

University of Oxford

On Feb. 29th the degree of D.M. was conferred on C. Wilson and of B.M. on J. F. Loutit.

University of London

Mr. Wilfred Trotter, F.R.S., has been appointed to the university chair of surgery at University College Hospital medical school.

Mr. Trotter, who is 63 years of age, was educated at University College where he graduated M.B. with first-class honours and was awarded the gold medal in 1896. He also received a gold medal and the university scholarship in surgery on taking the B.S. degree in 1899, and after obtaining other qualifications was appointed surgical registrar and lecturer in surgery at University College Hospital in 1901. Five years later he joined the honorary staff of the hospital and also of the East London Hospital for Children. A subsequent appointment, for a time, to the West End Hospital for Nervous Diseases, showed his bias towards neurological surgery and its underlying physiology, but he has also worked and reported on the surgery of the mouth and pharynx, on goitre, and on other and various subjects. His book on "Instincts of the Herd in Peace and War," which first appeared in 1916, has won him a collateral reputation as a biologist, and his published works include the Hunterian oration of 1932 and many lectures and addresses delivered before colleges and societies. Mr. Trotter is a member of the council of the Royal College of Surgeons of England and served on the Medical Research Council from 1929 to 1933. In 1928 he was appointed honorary surgeon to King George and in 1932 serjeant surgeon. He holds honorary doctorates from the Universities of Edinburgh and Liverpool and was elected F.R.S. in 1931.

The Graham Legacy committee have awarded a gold medal to Sir Thomas Lewis for research in connexion with the treatment of cardiac disease conducted at University College Hospital and medical school.

Prof. William Bulloch, F.R.S., has been appointed Heath Clark lecturer for the year 1936.

The title of Fellow of University College, London, was conferred on Dr. H. P. Himsworth, Mr. R. J. Ludford, D.Sc., Dr. Arthur MacNalty, and Mr. Julian Taylor.

University of Dublin

Mr. J. K. Jamieson, professor of anatomy and dean of the medical school at the University of Leeds, has been appointed to the chair of human anatomy and embryology at Trinity College, where he has for some time been examiner. He succeeds the late Dr. A. F. Dixon.

British Postgraduate Medical School

On March 17th, at 2.30 p.m., Dr. Leonard Colebrook will repeat the lecture on puerperal sepsis which he gave on March 2nd. The lecture is one of a course on recent advances in obstetrics and infant hygiene which is being given at the school, Ducane-road, Hammersmith, London, W.

New Ophthalmic Clinic

The King Edward Memorial Hospital, Ealing, is now providing a clinic in connexion with the Voluntary Hospitals Ophthalmic Clinic Scheme. It is held on Wednesday afternoons, and is open to members of approved societies and to contributors to the Hospital Saving Association. Those with incomes below a certain scale may also attend and are charged a fee of half a guinea and the cost of any spectacles prescribed.

Epsom College

The council of the College will shortly award a St. Anne's scholarship of £60 a year to an orphan girl, not less than nine years of age on July 15th, 1936, who is the daughter of a medical man who was at least five years in independent practice in England or Wales. Application must be made by May 15th on a form to be had from the Secretary of the College, 49, Bedford-square, London, W.C.1.

The council will also shortly award a Grewcock pension of £70 a year to a retired medical man who from old age, permanent incapacity from illness, reduced circumstances, or other cause is in need of it. There is no limitation as to age, but special consideration will be given to the claims of candidates having association with Worcestershire, Lincolnshire, or Carmarthenshire. Forms of application, which must be returned by the middle of May, can be had from the secretary.

Dr. William Warburton Pemberton has been appointed sheriff of Cambridgeshire and Huntingdonshire for the year 1936.

ON Monday, March 9th, the offices of the Radium Commission will be removed from 5, Adelphi-terrace, W.C.2, to 18, Park-crescent, Portland-place, W.1.

Institute of Psycho-Analysis

Dr. Ernest Jones will preside at three lectures on the emotional life of civilised men and women which will be given at the Caxton Hall, S.W., at 8.30 p.m. on Thursdays, March 12th, 19th, and 26th. The subject of the first lecture, by Dr. Sylvia Payne, is *Work and its Meaning for Us*. Tickets may be had from the secretary of the institute, 36, Gloucester-place, W.

Catholic Medical Congress

The second international congress of Catholic physicians meets in Vienna from May 28th to June 2nd, and the main subject for discussion will be eugenics and sterilisation. Full information may be had from The Oesterreichisches Verkehrsbureau, Friedrichstrasse 7, Vienna.

Nottingham General Hospital

To commemorate his 70th birthday Mr. W. G. Player has given £1000 to this institution.

Legacy for Swansea General Hospital

Mrs. Sarah Powell has left the residue of her estate, which is expected to amount to some £20,000, to this hospital. The money is to be used to build a new ward in memory of her brother, the late Sir Samuel Evans, and herself.

Clacton and District Hospital

The Silver Jubilee extensions to this hospital, which was built in 1899 to commemorate Queen Victoria's Diamond Jubilee, will be ready for opening by Easter. The extensions have cost about £10,000 and more money is needed to equip and furnish them. They include wards for abnormal maternity cases, electrical and massage departments, and an administrative block.

Hunterian Society

The gold medal which this society awards annually for the best essay written by a general practitioner has for the first time been given to a practitioner resident outside Great Britain. The subject set for 1935 was the conduct of midwifery in general practice, and the prize essay was submitted by Dr. Francis Bennett, of Christchurch, New Zealand. The subject chosen for 1936 is rheumatoid arthritis, its diagnosis, treatment, and end-results, and for 1937 the prognosis and care of heart disease in general practice. Further particulars may be had from the hon. secretary of the society, Mr. Arthur Porritt, 27, Harley-street, London, W.

Fellowship of Medicine and Post-Graduate Medical Association

Courses arranged for M.R.C.P. candidates are as follows: chest diseases, Brompton Hospital (March 10th to April 4th); chest and heart diseases at the Royal Chest Hospital (March 15th to April 4th). A demonstration on the fundus oculi will be given at the West End Hospital for Nervous Diseases on Tuesday, March 31st, at 8.30 p.m.; and a course in orthopedics at the Royal National Orthopaedic Hospital from March 9th to 21st; and in infant's diseases from March 30th to April 4th. Week-end courses include chest diseases, at the Brompton Hospital (March 7th and 8th); clinical surgery, at the Royal Albert Dock Hospital (March 14th and 15th); general medicine, at the Miller General Hospital (March 21st and 22nd); and urology, at the All Saints' Hospital (March 28th and 29th). Four lectures on diseases of children will be given by Dr. Reginald Lightwood at the National Temperance Hospital on March 25th, 27th, April 1st and 3rd at 8.30 p.m. Lectures are open only to members and associates, and further particulars may be had from the secretary of the fellowship, 1, Wimpole-street, W.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, March 9th.

United Services. 4.30 P.M. Squadron Leader R. H. Stanbridge: Occupational Selection of Aircraft Apprentices.

TUESDAY.

Therapeutics and Pharmacology. 5 P.M. Dr. G. Graham and Dr. S. Levy Simpson: The Treatment of Addison's Disease with Salt. Dr. E. N. Allott: The Effect of Treatment on the Blood Chemical Changes in Addison's Disease. Dr. Audrey Baker and Dr. Margaret Wright: The Vitamin B₁ Content of Human Diet.

Psychiatry. 8.30 P.M. Dr. Alfred Meyer: The Selective Regional Vulnerability of the Brain and its Relation to Psychiatric Problems.

WEDNESDAY.

Surgery: Sub-section of Proctology. 5 P.M. Mr. J. P. Lockhart-Mummery: 1. Spindle-celled Sarcoma of Buttock Treated by Radium. No Recurrence two years later. 2. Recurrence after Local Excision of Adenoma of Rectum. Mr. Lionel E. C. Norbury: 3-4. Extensive Papilloma of Rectum Removed by Perineal Excision. 5. Extensive Papilloma of Pelvic Colon Removed by Paul's Operation. Dr. Cuthbert Dukes: 6. Lymphatic Spread of Cancer of the Rectum. 7. Derivation of Fistulae from Intramuscular Glands. 8. Misplaced Epithelium (possibly Pancreas) within the Rectum. Mr. O. V. Lloyd-Davies: 9. Villous Papilloma of the Rectum.

FRIDAY.

Ophthalmology. 5 P.M. (Moorfields Eye Hospital, City-road, E.C.1), Mr. H. B. Stallard: 1. Sarcoma. 2-3. Glioma. 4-6. Coats' White Rings of the Cornea. Mr. F. A. Juler: 7. Congenital Retinal Fold. 8. Angioma of Orbit.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.

MONDAY, March 9th.—8.30 P.M., Mr. A. Dickson Wright: Phlebitis and its Treatment.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, March 12th.—8.30 P.M. (Manson House, 26, Portland-place, W.), Dr. H. Letheby Tidy: Treatment of Gastric and Duodenal Ulcer. (Harveian Lecture.)

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, March 13th.—8.45 P.M. (Miller General Hospital, Greenwich, S.E.), Dr. Harold Crampton: The Unexpected in Anaesthesia.

SOUTH-WEST LONDON MEDICAL SOCIETY.

WEDNESDAY, March 11th.—9 P.M. (Bolingbroke Hospital, Wandsworth Common), Dr. W. E. Lloyd: Clinical Meeting.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY, Royal Northern Hospital, N.

FRIDAY, March 13th.—9 P.M., Dr. J. L. Livingstone: Asthma.

PADDINGTON MEDICAL SOCIETY.

TUESDAY, March 10th.—9 P.M. (Paddington Tuberculosis Clinic, 20, Talbot-road, W.), Dr. H. W. A. Post: X Ray Films.

BIOCHEMICAL SOCIETY.

FRIDAY, March 13th.—2.30 P.M. (University College, Gower-street, W.C.), Short Communications and Demonstrations.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY.

THURSDAY, March 12.—8.30 P.M. (11, Chandos-street, W.), Sir Walter Langdon-Brown: The Place of Psychology in the Medical Curriculum.

NORTH-WEST LONDON MEDICAL SOCIETY.

TUESDAY, March 10th.—9 P.M. (Regal Rooms, Finchley-road, Golders Green), Dr. John Freeman: Immunology in General Practice.

LONDON JEWISH HOSPITAL MEDICAL SOCIETY, Stepney Green, E.

THURSDAY, March 12th.—4 P.M., Sir Edmund Spriggs, Dr. B. S. Nissé, Dr. J. B. Mennell, and Dr. F. Nagelschmidt: Rheumatism.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, March 10th, and THURSDAY.—5 P.M., Dr. R. A. McCance: Medical Problems in Mineral Metabolism. (Goulstonian Lectures.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields.

FRIDAY, March 13th.—5 P.M., Dr. L. W. Proger: Specimens illustrating Tumours of the Kidney.

INSTITUTE OF HYGIENE, 28, Portland-place, W.

WEDNESDAY, March 11th.—3.30 P.M., Prof. Winifred Cullis: Women in Industry.

ROYAL INSTITUTION, 21, Albemarle-street, W.

TUESDAY, March 10th.—5.15 P.M., Prof. Edward Mellanby, F.R.S.: Drug-like Actions of some Foods.

SIR CHARLES HASTINGS LECTURE.

TUESDAY, March 10th.—8 P.M. (B.M.A. House, Tavistock-square, W.C.), Prof. Winifred Cullis and Dr. R. Cove-Smith: Keeping Fit.

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane-road, W.

MONDAY, March 9th.—3.30 P.M., Prof. F. J. Browne: Toxemias of Pregnancy.

WEDNESDAY.—3.30 P.M., Mr. Eardley Holland: Haemorrhage of late Pregnancy (II).

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, March 9th.—10 A.M., Skin clinic. 11 A.M., Surgical wards. 2 P.M., Gynaecological and surgical wards, gynaecological and eye clinics. 4.15 P.M., Mr. Green-Armytage: Fevers of Pregnancy.

TUESDAY.—10 A.M., Medical wards. 11 A.M., Surgical wards. 2 P.M., Throat clinic. 4.15 P.M., Mr. Simpson-Smith: Minor Surgical Problems.

WEDNESDAY.—10 A.M., Children's ward and clinic. 11 A.M., Medical wards. 2 P.M., Eye clinic, gynaecological operations.

THURSDAY.—10 A.M., Neurological and gynaecological clinics. Noon, Fracture clinic. 2 P.M., Eye and genitourinary clinics. 4 P.M., Venereal diseases.

FRIDAY.—10 A.M., Medical wards and skin clinic. Noon, Lecture on treatment. 2 P.M., Throat clinic.

SATURDAY.—10 A.M., Children's and surgical clinics, Medical wards.

Daily, 2 P.M., Operations, Medical and Surgical Clinics. The lectures at 4.15 P.M. are open to all medical practitioners without fee.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, March 9th, to SUNDAY, March 15th.—INFANTS HOSPITAL, Vincent-square, S.W. Mon., Wed., and Fri., 8 P.M., Primary F.R.C.S. course in anatomy and physiology.—NATIONAL TEMPERANCE HOSPITAL, Hampstead-road, N.W. M.R.C.P. Clinical and pathological course. Tues. and Thurs. at 8 P.M. Tues., 8.30 P.M., Mr. T. Holmes Sellors: Thorax. Thurs., 8.30 P.M., Mr. R. Coyte: Large Intestine and Rectum. M.R.C.P. Clinical and pathological course at 8 P.M.—ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, Great Portland-street, W. All-day course in orthopaedics.—BROMPTON HOSPITAL, S.W. Mon., Tues., Thurs., and Fri., 5 P.M., M.R.C.P. class.—ROYAL ALBERT DOCK HOSPITAL, S.E. Sat. and Sun., course in clinical surgery.—Courses are open only to members of the Fellowship.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, S.W.

WEDNESDAY, March 11th.—4 P.M., Mr. Leonard Phillips: Puerperal Sepsis.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westminster-street, W.

TUESDAY, March 10th.—5.30 P.M., Dr. B. T. Parsons-Smith: Cardiac Breathlessness.

HAMPSTEAD AND NORTH WEST LONDON GENERAL HOSPITAL, N.W.

WEDNESDAY, March 11th.—4 P.M., Dr. H. M. Oddy: Some Aspects of Arterial Disease.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

WEDNESDAY, March 11th.—2 P.M., Dr. Alan Moncrieff: Epituberculosis and Hilum Tuberculosis. 3 P.M., Dr. D. N. Nabarro: Human and Bovine Tubercle.

Out-patient clinics daily at 10 A.M. and ward visits at 2 P.M.

NATIONAL HOSPITAL, Queen-square, W.C.

MONDAY, March 9th.—3.30 P.M., Dr. Symonds: Head Injuries (I).

TUESDAY.—3.30 P.M., Mr. Julian Taylor: Spinal Compression.

WEDNESDAY.—3.30 P.M., Dr. Kinnier Wilson: Clinical Demonstration.

THURSDAY.—3.30 P.M., Dr. Riddoch: Cerebral Tumours.

FRIDAY.—3.30 P.M., Dr. Purdon Martin: Demyelinating and Toxic Diseases of Nervous System.

Out-patient clinics daily at 2 P.M.

LEEDS GENERAL INFIRMARY.

TUESDAY, March 10th.—3.30 P.M., Dr. Towers: Faintness and Vertigo: Demonstration of Cardiac Cases.

MANCHESTER ROYAL INFIRMARY.

TUESDAY, March 10th.—4.15 P.M., Dr. J. Wharton: Iritis and Glaucoma.

FRIDAY.—4.15 P.M., Dr. Crighton Bramwell: Demonstration of Cardiac Cases.

ANCOATS HOSPITAL, Manchester.

THURSDAY, March 12th.—4.15 P.M., Dr. E. D. Gray: A Study of Chest Radiograms.

UNIVERSITY OF DURHAM.

SUNDAY, March 15th.—10.30 A.M. (Newcastle General Hospital), Mr. G. F. Duggan: Surgical Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.

WEDNESDAY, March 11th.—4.15 P.M. (Royal Maternity and Women's Hospital), Dr. R. A. Lennie: Ante-natal Care.

WEST CORNWALL MINERS' AND WOMEN'S HOSPITAL, REDRUTH.—New quarters for nurses were opened at this hospital on Feb. 18th. There are five bedrooms, which are centrally heated and have hot and cold water. The cost of the extension has been about £1000.

NOTES, COMMENTS, AND ABSTRACTS

POISONS FOR RODENTS

A TECHNICAL discussion on poisons for rodents was held at the College of the Pharmaceutical Society on Feb. 27th, under the auspices of the University of London Animal Welfare Society. Prof. J. H. Burn presided. It was made clear that the society did not propose to advocate any particular policy or to conduct propaganda at this meeting, but merely to survey the available information. The object of the discussion was to explore the feasibility of selecting and devising poisons for rats and other rodents which should cause as little suffering as possible. Mr. J. G. Wright, lecturer in surgery and materia medica at the Royal Veterinary College, summarised the pathological effects of hydrocyanic acid gas, and bait poisons including arsenic trioxide or potassium arsenite, phosphorus, strychnine, salts of thallium, barium carbonate, and red squill. All except the last two of these figure in Part I. of the list of poisons drawn up by the Poisons Board, and barium carbonate is in Part II. of the list, so that only red squill would be available for unrestricted distribution to the public. All the prohibited poisons produced severe and prolonged suffering. Red squill, when freshly and correctly prepared, was perhaps the least inhumane of the poisons that could be effectively used. It was specific for rats, more toxic for females than for males, and had little effect on domestic animals or man. The toxic principle contained in red squill was different from and additional to the glucosides which gave the drug therapeutic value. The essential action was upon the central nervous system. Symptoms were delayed for several hours after ingestion and began as a paralysis of the hind limbs, which progressively became more generalised, and were accompanied by convulsions of varying intensity, during which the animal might throw itself about. Death occurred in from one to three days from asphyxia following paralysis of the respiratory centre. Mr. Wright suggested as a useful line of research the search for a narcotic that could be combined with red squill, in order to provide unconsciousness during the onset of painful symptoms. Hydrocyanic acid, used for fumigating rabbits and rats in burrows, was the most rapidly acting poison known.

Mr. J. D. Hamer, consultant chemist to the Orient Line, put the poison question in due perspective by describing first the urgent reasons for combating the rat menace and secondly the normal methods employed for this purpose. The most important of these were rat-proofing of premises, elimination of nesting sites and supplies of food and water, and fumigation with hydrogen cyanide (which in view of its toxicity required skilled handling except in the open air). Traps and poison baits were relatively inefficient; if any were to be used he preferred red squill. Bacterial poisons he rejects as unsafe. Mr. T. Howard described the technique of the methods of baiting requisite to outwit the extremely high intelligence of the rat. He favoured a quick-acting poison of high toxicity, but such poisons could not be sold to the general public and were available only to the professional rat-catcher.

In the course of the general discussion which followed, a suggestion was made that research should be undertaken with the object of identifying the rat-toxic principle of red squill and of synthesising a kindred compound which by acting more rapidly would cause a more humane death.

THE COMMON COLD AGAIN

ANOTHER symposium on this vexed and vexing problem appears in the *Health Examiner* (published by the New York Academy of Medicine) for January, 1936. The authors are Dr. Russell L. Cecil, Dr. Yale Kneeland, Jun., and Dr. Walter L. Niles, all of New York. Dr. Cecil's foreword does not carry us far.

Having stated confidently that exposure to cold is the surest way to catch a cold, he devotes the rest of his article to a discussion of the treatment of pneumonia. Dr. Kneeland's contribution is more to the point. He holds the rational and modern view that the causa causans of the common cold is a filtrable virus which is, or may be, subsequently aided and abetted by the common pathogenic organisms present in the respiratory passages. In support of this view he quotes the work of T. H. Paul and H. L. Freese on the inhabitants of Spitzbergen who, during the seven months of the year in which they are ice-bound and so isolated from the rest of humanity, do not suffer from colds. In Dr. Kneeland's opinion, the solution of the problem lies in effectively immunising the human race against the virus. Dr. Niles suggests that the way to avoid colds would be to live in regions where they are infrequent; but would not the result of following such advice be to introduce colds into those happy regions? He holds that the public are still insufficiently alive to the seriousness of the cold as a communicable disease which, he thinks, should be handled in a manner similar to measles or scarlet fever. With regard to treatment he has nothing very new to offer. Many will agree with him when he says that there is a tendency to over-treat infected mucous membranes with ephedrine or cocaine. He is inclined to look with favour on the treatment of the cold by morphia or other alkaloids of opium as advocated by Diell and certain French physicians.

DEFENCE AGAINST AIR RAIDS

THE air raid precautions department of the Home Office has issued a circular to local authorities on "Anti-gas Training," and a leaflet on "Rescue Parties and the Clearance of Débris." These are obtainable from H.M. Stationery Office at 1d. and 2d. respectively. The circular states that a civilian anti-gas school will shortly be established at Eastwood Park, Falfield, Gloucestershire, and that local authorities and other responsible bodies will be expected to arrange for instruction to be given in their areas by persons who have obtained certificates after undergoing a general course of at least a fortnight at this school. Specialist one-week courses will also be given to doctors and nurses and to suitably qualified chemists. The first five courses at the school will be devoted to police and fire brigade instructors, but vacancies can be provisionally allotted for the whole of the first year. The memorandum on rescue parties forms part of a considerable series of official pamphlets and handbooks now in course of publication.

We have also received a copy of a monthly review described in a covering letter as the only journal in Bulgaria devoted to chemical warfare and the treatment of poison gas casualties. Its title, in French, is *Défense de Gaz. et l'Aéronautique*, and it is published from Boulevard Ferdinand 90, Sofia.

MINISTERING ANGELS ON HORSEBACK

THE condition of rural midwifery in the United States still leaves much to be desired. A recent report¹ on Brunswick County, Va., expresses the opinion that many of the rural midwives there are physically and mentally unfit to practise. No such criticism, however, is true of Kentucky where Mrs. Mary Breckinridge founded the Frontier Nursing Service in 1925. This service now covers an area of more than 700 square miles. There are nine nursing centres and some thirty nurses who, owing to the nature of the country, have to travel about

¹ U.S. Public Health Reports, Dec. 27th, 1935. *The Rural Midwife: Her Social and Economic Background and Her Practices as Observed in Brunswick County, Va.* By Josephine L. Daniel, Research Worker in Child Hygiene and Public Health Nursing; and William M. Gatafer, Senior Statistician, United States Public Health Service.

on horseback. The service also includes a medical director, an 18-bed hospital, and, during the summer months, a dentist. In addition there are a social worker, a statistician, and a volunteer courier service. Though midwifery was the first and remains the primary function, the work has expanded and now includes the care of the sick of both sexes and all ages, social service, and education in preventive medicine and child welfare. Up to May, 1931, costs worked out at the remarkably low figure of \$10.92 a year per patient. During the great drought of 1930, which brought dysentery, typhoid, small-pox, diphtheria, pneumonia, and influenza in its train, the nurses covered an area of 1000 miles, tending the sick and chlorinating wells. This admirable service is an example of what can be done by courage and enterprise in remote areas.

A GUIDE TO INCOME-TAX PROBLEMS

THERE exist full-dress text-books on income-tax for experts, heavy loads of information usually at a heavy price, containing every word of the Income Tax Act and of the amending sections in annual Finance Acts, annotated with every decided case. The "Income Tax Guide," by Mr. John Burns,¹ is of less formal character: a convenient summary which the tax-payer can study for himself, clearly written and inexpensive. In the new edition, miraculously shorter even than its predecessor, the main change is the substitution of the new scale of reliefs under last year's Finance Act. Chancellors of the Exchequer have promised simplification of the law. The committee of experts, set up by Mr. Winston Churchill several years ago, has its report and its draft code in type; it is possible that the existing enactments will be consolidated in an improved form in a year or two. Meanwhile there are few tax-payers who do not need guidance; within its own range Mr. Burns's little book will be found serviceable. It contains pages of special interest to doctors and dentists.

NEW PREPARATIONS

"IOZO" WHITE STAINLESS IODISED OINTMENT contains 6 per cent. of potassium iodide and 3 per cent. of methyl salicylate in a neutral saponaceous base. It leaves no mark on the skin and is recommended for external application in cases of rheumatic pain, chilblains, cuts, bruises, burns, and other conditions. The makers are Christopher, Stanley and Co., Ltd., Thames House, Millbank, London, S.W.1.

PETEIN is a whooping-cough vaccine, for intramuscular injection, prepared by Schering-Kahlbaum A.G., of Berlin, and sold in this country by Schering Ltd., 188, High Holborn, W.C.1. About 60 distinct strains of *Hæmophilus pertussis*, collected in various epidemics, are used in its composition, and care is taken to preserve their activity. The principal advantage claimed for Petein, as compared with other whooping-cough vaccines, is that the bacterial toxin has been removed from the bacterial cells, which makes it "entirely innocuous" even in large doses. The detoxication of each batch is verified by intradermal inoculation into guinea-pigs or rabbits, and is considered satisfactory if the animal shows no reaction after receiving double the maximum dose employed in man. The course advised is four injections, administered on alternate days, ranging from 0.25 to 1.0 c.cm. (total 2.5 c.cm. = 50 million organisms). According to the manufacturers such a course is useful not only for prophylaxis but also for the treatment of whooping-cough, as late as the early stages of the convulsive phase of the cough. The benefit is observed 3-4 days after the last injection; at this point "the severe paroxysms of coughing and the vomiting cease abruptly," though occasionally the paroxysms may have been aggravated for a time during the actual treatment. The only other untoward effect noted is that rarely the fourth injection

leads to a slight rise of temperature with some local pain, both being attributed to the protein present in the vaccine. In support of their claims Messrs. Schering quote observations by E. Krüger (1934) and M. Richter (1934); but these are suggestive rather than conclusive.

A-B-D CAPSULES, made by Abbott Laboratories Ltd., of Montreal (52A, Wigmore-street, London, W.1), are soluble gelatin capsules containing a preparation of fish-liver oils and yeast rich in vitamins A, B₁, B₂, and D. It is stated that each is equivalent in A and D content to at least three teaspoonfuls of cod-liver oil (U.S. Pharmacopeia, 1934), and in B₁ content to about an ounce of moist compressed yeast. Expressed more accurately each capsule supplies not less than 6200 units of vitamin A and 900 units of vitamin D (U.S.P.), and not less than 45 Sherman units of vitamin B₁ and 10 Sherman units of vitamin B₂. Since these factors are "often obtained in inadequate amounts from the diet" Messrs. Abbott maintain that their administration is "essential for good health and well-being." The average dose proposed is 1 to 3 capsules daily or more during pregnancy and lactation.

BROM-NEVACIT, described as a nerve tonic, consists of potassium bromide 4 per cent., sodium phosphate 0.1 per cent., barbitone 0.33 per cent., phenazone 0.67 per cent., and alcohol 7.5 per cent., with flavouring of saccharin caramel, orange, and quinine. The manufacturers, Brom-Nevacit Ltd. (47, Crogsland-road, London, N.W.1), claim that their mixture has a soothing and curative influence on nervous disorders without unpleasant or harmful after-effects.

A CORRESPONDENT inquires whether any convalescent home is known to our readers which would admit a hospital patient with a suprapubic cystostomy between the two stages of an operation for enlarged prostate.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED FEB. 22ND, 1936

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 2536; diphtheria, 1265; enteric fever, 29; acute pneumonia (primary or influenzal), 1621; puerperal fever, 50; puerperal pyrexia, 110; cerebro-spinal fever, 31; acute poliomyelitis, 11; encephalitis lethargica, 7; dysentery, 34; ophthalmia neonatorum, 71. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on Feb. 28th was 4910, which included: Scarlet fever, 975; diphtheria, 1062; measles, 1498; whooping-cough, 720; puerperal fever, 18 mothers (plus 14 babies); encephalitis lethargica, 283; poliomyelitis, 4. At St. Margaret's Hospital there were 28 babies (plus 14 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox or enteric fever, 78 (11) from measles, 10 (1) from scarlet fever, 37 (12) from whooping-cough, 39 (8) from diphtheria, 59 (15) from diarrhoea and enteritis under two years, and 119 (10) from influenza. The figures in parentheses are those for London itself.

The mortality from influenza has risen a little, the total deaths for the last twelve weeks (working backwards) being 119, 97, 85, 98, 104, 89, 110, 110, 80, 67, 62, 45. The deaths this week are scattered over 56 great towns, Manchester reporting 8, Leeds 6, Blackburn and Birmingham each 4, Ilford, Southgate, Blackpool, Hull, Sheffield, Coventry, and Nottingham each 3, no other great town more than 2. Liverpool reported 16 deaths from measles, Manchester 14, Warrington 5, Bradford, Salford, and Bristol each 4. Deaths from diphtheria were reported from 20 great towns: 3 each from Bradford, Hull, and Warrington, 2 each from Leeds, Newcastle-upon-Tyne, Oldham, Sheffield, Wallasey, and Birmingham.

The number of stillbirths notified during the week was 283 (corresponding to a rate of 45 per 1000 total births), including 37 in London.

¹ Income Tax Guide. Ninth edition. By John Burns, Writer to the Signet. London: Sir Isaac Pitman Ltd. 1935. Pp. 214. 5s.

Appointments

CULLINAN, E. R., M.D., F.R.C.P. Lond., has been appointed Hon. Physician to the Gordon Hospital, Vauxhall Bridge-road, London.

FINLAYSON, D. I. C., M.B., F.R.C.S. Edin., Resident Medical Officer and Registrar at the Birmingham Maternity Hospital.

HEALEY, F. H., M.D. Birm., D.P.M., Senior Assistant Medical Officer at the Somerset and Bath Mental Hospital, Cotford.

Vacancies

For further information refer to the advertisement columns

Aberdeen Royal Infirmary.—Surgical Registrar. £200.

Altrincham General Hospital.—Sen. H.S. At rate of £150.

Aylesbury, Bucks Mental Hospital, Stone.—Sen. Asst. M.O. £600. Also two Jun. Asst. M.O.'s. Each £350.

Bath and Wessex Children's Orthopaedic Hospital, Combe Park.—H.S. At rate of £120.

Bath Royal United Hospital.—H.S. At rate of £150.

Beckenham, Bethlem Royal Hospital, Monks Orchard.—Two Res. H.P.'s. Each £175.

Belfast, Royal Maternity Hospital.—Res. H.S. At rate of £100.

Birmingham City.—Asst. M.O. for Maternity and Child Welfare. £500.

Birmingham, Erdington House.—Deputy M.O. £800.

Birmingham, Little Bromwich Hospital for Infectious Diseases.—Jun. Res. M.O. £300.

Brighton, New Sussex Hospital for Women, Windlesham-road.—H.P. £100.

Bristol City and County, Child Guidance Clinic.—Psychiatrist. At rate of £500. Also Social Worker. £275.

British Postgraduate Medical School.—Two Cas. O.'s. At rate of £150.

Buxton, Devonshire Royal Hospital.—H.P. At rate of £150.

Canterbury, Kent County Mental Hospital, Chartham Down.—Med. Supt. £1000.

Cardiff Royal Infirmary.—H.S. to Ophth. Dept. At rate of £40.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Two Hon. Assts. for Out-patient Dept.

Chadderton, U.D.—M.O.H., &c. £800.

Chester, Barrowmore Hall, Great Barrow.—H.P. At rate of £150.

City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.—Physician to In-patients.

Colonial Medical Service.—Med. Supt. for Colonial Hospital, Port of Spain. £1400.

Croydon, Mayday Hospital.—Jun. Res. Asst. M.O. £300.

Derby, Breiby Hall Orthopaedic Hospital, near Burton-on-Trent.—Asst. M.O. At rate of £150.

Deunbury and District General Infirmary.—Second H.S. £150.

Dudley, Guest Hospital.—H.S. £200.

Eastbourne, Princess Alice Memorial Hospital.—Res. H.S. £150.

Edinburgh, General Board of Control.—Deputy Commissioner. £738.

Glasgow Eye Infirmary.—Res. H.S. Also Res. Asst. H.S. Each £100.

Gloucestershire Royal Infirmary.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.

Great Western Railway Medical Fund Society, Swindon.—Chief M.O. £1200.

Guildford, Royal Surrey County Hospital.—Res. Surg. O. £250.

Hampstead General and N.W. London Hospital, Haverstock Hill, N.W.—Cas. M.O. for Out-patient Dept. At rate of £100.

Harrow Urban District.—Asst. M.O. £600.

Hertford County Hospital.—Hon. Clin. Asst.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. H.P. and Res. H.S. Each at rate of £100.

Huddersfield County Borough.—Asst. M.O.H. £500.

Huddersfield Royal Infirmary.—H.P. and Res. Anaesthetist. Also H.S. Each at rate of £150.

Institute of Medical Psychology, Maltr-place, W.C.—Part-time Psychotherapist. At rate of £200.

Institute of Ray Therapy, &c., Camden-road, N.W.—Part-time M.O. At rate of £100.

Kent County Council.—Res. Asst. M.O.'s for County Hospital. Each £250.

Kent Education Committee.—Asst. M.O. £500.

Lancaster County Mental Hospital.—Asst. M.O. £500.

Leamington Spa, Warwick General Hospital.—Res. H.S. to Cas. and Spec. Depts. At rate of £150.

Leyton Borough, Education Committee.—Part-time Orthoptic Worker. 15s. per session.

Lincoln County Hospital.—Jun. H.S. At rate of £150.

London County Council.—Temp. District M.O. At rate of £290.

London Hospital, E.—Med. First Asst. and Recr. £300.

London University.—University Chair of Biochemistry. £1000. Also University Readership in Anatomy. £600.

Macclesfield General Infirmary.—Second H.S. At rate of £150.

Maidenhead Hospital.—Hon. Ophth. Surgeon.

Maulstone, County Pathological Laboratory.—Asst. Pathologist. £700.

Maidstone, West Kent General Hospital.—H.P. £175.

Manchester, Ancoats Hospital.—H.S. At rate of £100.

Manchester, St. Mary's Hospital.—Four H.S.'s. Each at rate of £50.

Mansfield, Harlow Wood Orthopaedic Hospital.—Two H.S.'s. At rate of £200.

Middlesex County Council.—Asst. M.O. £600.

Mount Vernon Hospital, Northwood, Middlesex.—Asst. Radiologist. £350.

Newcastle-upon-Tyne Royal Victoria Infirmary.—Jun. Surg. Reg. £150.

Newport, Mon, Royal Gwent Hospital.—Asst. Cas. O. Also two H.S.'s and H.P. Each at rate of £135.

Northampton General Hospital.—H.P., H.S.'s, also Cas. O. Each at rate of £150.

Northumberland County Council.—Asst. County M.O.H. £500.

Norwich, Jenny Lind Hospital for Children.—Res. M.O. £120.

Nottingham General Hospital.—H.S. for Fracture and Orthopaedic Dept. £300. Also H.S. to Ear, Nose, and Throat Dept. At rate of £150.

Plymouth, Prince of Wales's Hospital, Lockyer-street.—H.S. At rate of £150.

Plymouth, Prince of Wales's Hospital, Greenbank-road.—H.S. At rate of £120.

Port Said, British Hospital.—Principal M.O. £700.

Preston, Wroughton Hospital, Appley Bridge.—Jun. Asst. M.O. £200.

Princess Elizabeth of York Hospital for Children, Shadwell, E.—H.P. At rate of £125.

Queen's Hospital for Children, Hackney-road, E.—Clin. Asst. to Ophth. Dept. 5s. per session.

Rochdale Infirmary and Dispensary.—Second H.S. £150.

Ross Institute of Tropical Hygiene, Keppel-street, W.C.—M.O.'s for East Africa, &c.

Rotherham Hospital.—Cas. H.S. £150.

Royal College of Surgeons of England.—Examiners.

Royal National Orthopaedic Hospital, 234, Great Portland-street, W.—H.S. At rate of £150.

Royal Northern Hospital, Holloway, N.—H.S. At rate of £70.

St. Alban's and Mid Herts Hospital.—Res. H.S. £150.

St. Andrew's Hospital, Deacons-road, Bow, E.—Asst. M.O. £350.

Salisbury General Infirmary.—H.S. At rate of £125.

Scarborough Hospital and Dispensary.—Two H.S.'s. Each £175.

Sheffield Children's Hospital.—H.P. At rate of £100.

Sheffield, Jessop Hospital for Women.—Res. M.O. Also two H.S.'s. At rate of £150 and £100 respectively.

Sheffield University, Dept. of Bacteriology.—Jun. Asst. Bacteriologist and Demonstrator. £300.

South Shields, Ingham Infirmary.—Jun. H.S. £150.

Stockport Infirmary.—H.P. £150.

Sunderland Royal Infirmary.—H.P. £120.

Taunton and Somerset Hospital.—H.S. At rate of £100.

University College Hospital, Gower-street, W.C.—Asst. Radiologist. £200.

Uzbridge, Hillingdon County Hospital.—Jun. Res. Asst. M.O. At rate of £250.

Warrington Infirmary and Dispensary.—Third Resident. At rate of £150.

West London Hospital, Hammersmith-road, W.—H.P. and H.S. to Spec. Depts. and Res. Cas. O. Each at rate of £100. Non. Res. Cas. O. £250. Also Physician.

West Sussex County Council, &c.—Asst. County M.O.H., &c. £800.

Wolverhampton Royal Hospital.—H.S. for Orthopaedic and Fracture Dept. At rate of £100.

Wretham and East Denbighshire War Memorial Hospital.—Two Res. H.S.'s. Each at rate of £150.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Walton-on-the-Naze (Essex), Calvert (Buckingham), Croydon (Surrey), and Swanscombe (Kent).

Births, Marriages, and Deaths

BIRTHS

ANDERSON.—On Feb. 26th, at Brantree, the wife of Dr. David M. Anderson, of a daughter.

CAUGHEY.—On Feb. 29th, at Collingham-gardens, S.W., the wife of Dr. F. W. H. Caughey, of a daughter.

FERGUSON.—On March 1st, 1936, at York-place Nursing Home, Manchester, to Kathleen (née Wilson), wife of Fergus R. Ferguson, a son.

PEREIRA.—On Feb. 28th, at Alexandra Park, N., the wife of Dr. Harold Pereira, of a daughter.

REEVES.—On Feb. 27th, at Southsea, the wife of Dr. R. K. Reeves, of a son.

MARRIAGES

CLEGG—EASON.—On Feb. 22nd, at Southwark Cathedral, William Bernal Clegg, M.R.C.S. Eng., of Wilmslow, Cheshire, to Diana Clare, daughter of the late Hon. Mrs. Eason and of Mr. H. L. Eason, Superintendent's House, Guy's Hospital.

COPLAND—DOUGLAS.—On Feb. 27th, at the Caledonian Hotel, Edinburgh, James George Copland, M.D. Aberd., of Huddersfield, to Margaret Cruickshank Douglas, M.B., D.P.H., younger daughter of Mr. Joseph and the late Mrs. Douglas, Colinton, Edinburgh.

ELLMAN—SAMUELL.—On Feb. 27th, at the Liberal Jewish Synagogue, London, Philip Ellman, M.R.C.P. Lond., of Harley-street, W., to Betty, elder daughter of Mr. and Mrs. Albert L. Samuell, of Cumberland-terrace, Regent's Park, N.W.

DEATHS

BURNETT.—On Feb. 26th, at Keswick, John Ridley Burnett, M.D. Edin.

COAD.—On Feb. 27th, at Tunbridge Wells, John Edwin Coad, Surgeon Captain, R.N. (retired).

COPESTAKE.—On Feb. 29th, at Peckham Rye, London, Thomas Goodall Copestake, M.B. Glasg.

HODSON.—On Feb. 26th, at Canterbury, Eleanor Hodson, M.B. Edin., Chevalier Légion d'Honneur, Médaille d'Honneur, elder daughter of the late Mr. and Mrs. Hodson, of Mickleover, Derbyshire.

TAYLOR.—On Feb. 27th, at Deepdale, Scarborough, Edward Muscroft Taylor, L.R.C.P. Edin., aged 78.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

THE NUTRITION QUESTION

BY ROBERT HUTCHISON, M.D., LL.D. Edin.,
F.R.C.P. Lond.

CONSULTING PHYSICIAN TO THE LONDON HOSPITAL

THE subject of nutrition is at present much to the fore; it may, indeed, be regarded as the public health "stunt" of the moment though maternal mortality runs it close. Unfortunately, too, it is a subject which has got badly mixed up with politics with the consequence that much of the writing about it in the lay and even in the medical press is of a tendentious character. This is a pity, for nutrition and its relation to health is a more complicated matter than is often realised and there is no subject which more requires cool and clear thinking.

What is Meant by Nutrition

At the outset we are met with the difficulty of defining our terms. According to the dictionary, nutrition is "the action or process of supplying or receiving nutriment," but this does not carry us very far. Perhaps one might describe normal nutrition as a state in which the intake of energy balances the output; in which the food contains enough protein and mineral matters for the purposes of growth and repair and in which the supply of the accessory food factors is adequate to prevent disease. But the "nutrition" of any individual is not a fixed and static thing; on the contrary it is, like health, capable of various degrees. If, for example, a man gains 5 lb. in weight is he necessarily better nourished than he was before? Or if he loses 5 lb. is his nutrition necessarily worse? What, in short, is the *optimum level* of nutrition? Should we aim, as some enthusiasts would have us do, at feeding children in such a way as to produce the maximum growth and development of which each child is capable? If we succeed in this are we sure we have benefited the child? Does maximum growth make for health and longevity? There is certainly some experimental evidence that it does not¹ and general experience seems to show that the tallest people are not the most robust and that the well-developed athlete is not necessarily a better "life" than the more fragile man. May it not be that the smaller and more wiry type fits in better with the conditions of urban life and a machine age?

These are only some of the questions to which there are as yet no agreed answers and although it might be true simply to say that optimum nutrition is that condition in which the body is at its highest pitch of vitality, there exists unfortunately no means of measuring that quality.

Assessment of Nutrition

There is, in fact, no accepted standard of nutrition in spite of many attempts to find one,² no "yardstick"—to use Prof. Cathcart's term—by which we can measure exactly what the state of nutrition in any individual is. The Quetelet Index or the relation of weight to height is, of course, of some help and it is probably true that if a child under 12 is less than 10 per cent. below or 20 per cent. above the average weight for his height he may be regarded as normal (Holt). But only quantitatively normal, for nutrition may be badly wrong in quality although

the body-weight is perfectly correct. We are thus driven to the conclusion that the state of nutrition can only be estimated in the same way as that of health; it is essentially a clinical problem to be determined by clinical methods. Unfortunately, however, it is just in the use of such methods that wide experience is most required and the personal equation of the observer counts for so much. It is not surprising therefore that the estimates by school medical officers of the amount of "malnutrition" in their districts vary considerably.

Assessment of Diets

It is sometimes assumed that although we cannot easily determine what *optimum* nutrition is, at least we can tell the kind of diet both in quantity and quality which can be guaranteed to produce it. Much of the criticism of present-day diets is based on this assumption, but is it correct? If we look at such a comparatively simple problem as energy requirement we find that three different committees of experts, appointed in recent years by the Ministry of Health, the British Medical Association, and the League of Nations respectively, have each recommended a different calorie value to maintain efficiency. There is even less agreement about the optimum protein intake. It was originally fixed by Voit at 120 g., and this figure was generally accepted at the beginning of this century until challenged by Chittenden. It is now often put at the round figure of 100 g., but we have the authority of Sir Gowland Hopkins for the statement³ that Cambridge undergraduates (not surely an under-nourished class) do not on an average consume more than 80 g., although a very high proportion of this is probably "first class." But here again we lack scientific guidance. There are some who say that half of the intake of protein should be of this superior kind, whilst others content themselves with recommending about a third. The point is one of importance, for first-class protein, being mainly of animal origin, adds greatly to the cost of the diet and yet there is no scientific justification for any positive pronouncement as to the exact amount of it required for optimum nutrition. If this is true of protein it is equally true of the mineral matters in the diet and of the "accessory factors"; estimates of the quantity of these required to maintain health are largely a matter of guesswork. If one adds to these uncertainties the inconstant composition of most foods and the doubtful allowance which has to be made for "waste" in the case of different individuals or households one sees on what shaky foundations our conception of an "optimum diet" is based.

In spite, however, of this absence of mathematical certainty in our criteria it is useful to distinguish between (1) "under-nutrition," meaning by that a state of things brought about by an inadequate intake of energy (calories), and (2) "malnutrition," a condition due to an ill-balanced diet or one deficient in building material or some of the accessory factors. Such a distinction, though convenient, is of course quite artificial, for in practice under-nutrition and malnutrition more often than not coexist.

Effects of Under-nutrition

It is commonly said that the effects of an insufficient intake of energy in the form of food is to lessen first activity and then resistance to disease. Such a statement needs qualification. It is amazing

L

how much activity some grossly under-nourished persons exhibit—patients with anorexia nervosa for instance—and, as regards resistance to disease, clinical experience tends to show that under-nourishment must be very pronounced before any general lowering of resistance is brought about. There is only one disease, indeed, to which beyond all doubt under-nutrition, even of moderate degree, predisposes, and that is tuberculosis. It was the supervention of tuberculosis that one dreaded in the case of young diabetics who were treated in the pre-insulin days by Allen's starvation plan and that one dreads still in patients with anorexia nervosa. In Germany, during the food shortage of the war, the death-rate from tuberculosis rose enormously whilst that from diabetes (a disease of over-nutrition) fell. Even in this instance, however, there is some evidence that it is not a shortage of calories as such (i.e., under-nutrition) that weakens resistance but poverty of the diet in fat (i.e., malnutrition), though whether it is the fat itself that is important, or a vitamin of which fat is the vehicle, is undetermined. As regards other infections, there is little evidence that under-nourishment, at least in moderate degrees, favours their development. It does not seem to do so, for instance, in the case of acute rheumatic infection in childhood, or the common acute specific fevers, or *B. coli* infections or acute poliomyelitis, or infection by pyogenic organisms; indeed Dr. Friend⁴ records that at Christ's Hospital the health of the boys, as regards septic infections and possibly in some other respects, "was actually better during the period of restricted food supplies." There is more doubt about respiratory infections other than tuberculosis; at least there was an increased mortality from these in Germany during the time of food shortage just as there was from tuberculosis itself. On the other hand Chable,⁵ in an investigation in a Swiss canton where there was a large amount of unemployment, found no deterioration of health in spite of restricted rations, indeed it was better at all ages, and curiously enough there was even less tuberculosis. He attributes these results to the cessation of heavy manual work so that the diminished intake of food sufficed.

Effects of Malnutrition

If the effect of a moderate degree of *under-nutrition* in predisposing to disease is uncertain, it is even more difficult to estimate the consequences of *mal-nutrition*. Take, for instance, the case of protein. What, if any, are the ill-effects of living habitually on a protein minimum? We have no clear evidence to guide us to a decision. Some persons seem to be able to live normally for very long periods on a protein intake which is only about half the generally accepted standard, whilst others on the same allowance have complained after a time of "impaired health," lack of energy, and shortness of breath.⁶ The condition known as war oedema has also been attributed, rightly or wrongly, to protein shortage, but as regards the effect of the latter in predisposing to disease we really know very little. The same is even more true of the mineral constituents of the diet. That these are essential to life is of course beyond dispute, but as regards the consequences to health which follow the consumption of them in quantities below those fixed by dietitians as "standards" we really know very little. Shortage of iodine in the diet seems to produce goitre and lack of iron is sometimes—though usually (except in infancy) only in the presence of habitual losses of blood—a cause of anæmia, but is there any clinical

condition other than rickets and osteomalacia which can be attributed to a diet poor in calcium? Even these diseases, moreover, are usually brought about not by lack of calcium itself but of a sufficiency of vitamin D to enable the calcium to be utilised.

And what of malnutrition due to deprivation of the accessory factors (vitamins)? We know of course that absence of these (avitaminosis) results in the appearance of certain specific diseases—xerophthalmia, rickets and osteomalacia, beri-beri, scurvy. But what is the effect on health of ingesting only minimal quantities of vitamins (hypovitaminosis)? About this there has been a good deal of vague talk, emanating from experimentalists rather than from clinicians, so it will be as well to consider each vitamin separately.

Vitamin A has been proved to prevent xerophthalmia and night-blindness. Green and Mellanby⁷ found that a lack of it in the diet of experimental animals led to broncho-pneumonia, and they also advanced some evidence to show that its administration lessened the risk of puerperal infection in women. It was therefore labelled, rather hastily, the "anti-infective" vitamin, and began to be prescribed in concentrated form in all sorts of infections. The results, however, were not impressive, and subsequent clinical investigation on a large scale with adequate controls has shown that, in fact, vitamin A has no general "anti-infective" power except possibly as regards some mild infections of the skin.⁸

Vitamin B, of course, is not a single vitamin but a complex of more than one. One fraction of it has been proved to protect against beri-beri and another may possibly play a part in protecting against pellagra, but beyond these there are no definite diseases in man associated with a lack of it. Experimentalists have ascribed ill-defined disorders of the intestine to a shortage of this vitamin, but it may safely be said that no such association has been recognised by clinicians. Only the other day I was asked by a commercial traveller to believe that an artificial preparation of the vitamin-B complex which he was trying to sell was "good for neuritis." On cross-examination, however, he proved quite uncertain as to what variety of neuritis was meant. This is a good example of the way in which the vitamins are being exploited commercially on the strength of the most flimsy evidence.

Vitamin C protects against scurvy—that is proved—and the fact that scurvy, other than the infantile form, is now almost extinct in this country shows that our ordinary diet contains enough of it; much, probably, in that popular article, the potato. Here again attempts have been made to show that there are conditions of ill-health short of actual scurvy due to a scarcity of vitamin C in the diet, and some evidence has been brought forward that an increased fragility of the capillaries can be demonstrated in such circumstances. But do clinicians often see such cases, which would of course be bound to display themselves by bruising and extravasations on slight provocation? I think not. Even less convincing to the paediatrist I fancy will be the recent attempts to make out that deficiency of vitamin C plays a part in the production of acute rheumatism.

As a matter of fact the striking thing about ascorbic acid (vitamin C) is the very negative effect it seems to have on bodily functions and metabolism even when given in massive doses.⁹

Vitamin D prevents rickets and some of its com-

plications in the growing child, and may also, though less certainly, help in the building up of sound teeth, so during the early years of life a sufficient supply of it in the diet is of great importance. To the adult it is much less essential. Osteomalacia may be the consequence of a deficiency, but that is a very rare disease in this country, and there is no other clinical condition, so far as I know, which results from a shortage of it in the diet as distinct from a failure to utilise it.

The So-called Protective Foods

The term "protective foods" has been applied, rather unfortunately, to dairy products, green vegetables, and fruits on the ground that they protect us against disease and, as thought-saving catch-phrases so often do, it has caught on. But this group of foods is really no more deserving of the title "protective" than sugar and the other calorie-rich foods which, after all, protect us against starvation. The protective foods do prevent the development of a few specific maladies (though meat which is not included amongst them does so too), but there is no proof whatever that they protect us against any of the great killing diseases to which most of the mortality in this country is due.

Over-nutrition and Under-nutrition

The existence of any widespread under-nutrition in this country (always a priori unlikely, except perhaps in the "distressed areas") most official information contradicts, and the experience of practitioners in close touch with the poorer classes will probably confirm the contradiction. Against it also is the fact that diseases such as tuberculosis which are associated with under-nutrition are steadily declining, whilst the incidence of diabetes and cardiovascular disorders, which are associated with good nutrition, is increasing. Enthusiasts for feeding-up the community should take note of this, for over-nutrition has dangers to health almost as great as those of under-nutrition, though of a different kind, and hypervitaminosis is beginning to be recognised as well as hypovitaminosis.

Moreover, of the under- or mal-nutrition which exists a very large part is almost certainly not due to inability to get enough food of the right kind but to such factors as lack of appetite, the consequence of indoor occupation and urban life; to educational over-strain amongst children; and, as J. C. Spence found in the Newcastle district, to infective disease in early life (possibly favoured by overcrowding), recovery from which had never been complete. To these must be added nervous wear and tear and psychological factors in many instances. Sheer poverty, in short, is only one cause, and that probably not a common one of present-day malnutrition.

It may well be, of course, that expenditure upon food is often unwisely directed, and that there is much unnecessary waste. There is room here for educative propaganda, but he is a sanguine man who believes that it is easy to change by this or any other means the food habits and prejudices of a people.

Summary

I might summarise the purport of this paper in the statement that it is intended to be a protest: (1) against the pessimistic view, apparently so commonly held, that defective nutrition is widely prevalent in this country; and (2) against the undue optimism which believes that a great improvement in the public health can be brought about by altering the national diet.

SOME OBSERVATIONS ON PEPTIC ULCER*

By DANIEL T. DAVIES, M.D. Wales, F.R.C.P. Lond.

ASSISTANT PHYSICIAN TO THE ROYAL FREE HOSPITAL,
LONDON

(Concluded from p. 526)

Gastric Secretion in Cases of Ulcer

Since experiment demonstrates that active gastric secretion is essential to the development of peptic ulcer in animals, it is difficult to explain the coexistence of achlorhydria and an active ulcer. We should expect to find in ulcer patients a juice possibly more copious and an acidity often higher than which is seen in normal people. Clinical experience unquestionably supports this view. Indeed it is well recognised among the more surgically minded that the higher the acidity the more the danger of further ulceration. While a gastro-enterostomy for carcinoma never results in secondary jejunal ulceration, this complication is not a rare sequel to operation for peptic ulcer, especially when the patient is young and the juice high in volume and acidity.

In an able review of 1435 ulcer patients, Emery and Monroe²⁴ were able to recall "no instance in which an ulcer gave characteristic symptoms in the absence of HCl." Brown²⁵ also recorded hyperacidity in 75 per cent., normal acidity in 22 per cent., and an acidity below 20 units in only 3 per cent.—an observation from a total of 1224. Palmer²⁶ likewise found free acid in all but 1 of 1004 ulcer patients. Hurst,²¹ Bennett,²⁷ and Venables,²⁸ have also drawn attention to the high acid secretion. More recently Pyrah²⁹ recorded the presence of free HCl in all but 1 of 197 duodenal ulcers.

Scott Pollard and Bloomfield^{30 31} in their accurate studies of gastric secretion maintain that in over 90 per cent. of ulcer cases there is an increase higher than the mean values, both in volume and acidity, as a result of histamine stimulation. At the same time they point out that while almost all patients with ulcer show this high acid and high volume secretion, similar values are also found occasionally in persons not suffering from this condition.

* The Bradshaw lecture for 1935, delivered before the Royal College of Physicians of London on Nov. 5th.

Recently Osterberg and Vanzant³² have drawn attention to the high pepsin values which are specially found in duodenal ulcer when the symptoms are somewhat difficult to control. They also were able to show that highly nervous individuals with the ulcer syndrome but without an actual lesion showed similar high readings in the gastric secretion.

Gastric secretion varies with age. According to Vanzant³³ (in a study of 3746 records) gastric acidity reaches its maximum between the age of 20 and 40 in the male, but there is little fluctuation in the acid values in the female. Over the age of 60 there is a decline and an increasing incidence of anacidity. It is of interest to recall that the maximum incidence of benign ulcer is between 30 and 40 years, and that the male suffers more often than the female.

TABLE VI
Gastric Analysis in Ulcer

	G.U.	D.U.	Total.
Hyperacidity ..	37	76	113 (60%)
Normal acidity ..	47	27	74 (39%)
Achlorhydria ..	—	1	1

Among my patients 188 had gastric analyses, many of them repeatedly. We found hyperacidity in 60 per cent. and an acidity within the range of normal in 39 per cent. (Table VI.).

Only 33 of the 188 showed a resting juice volume below 40 c.cm., and 70 per cent. of the gastric and 92 per cent. of the duodenal cases showed a resting juice volume of above 40 c.cm. (Table VII.). In

TABLE VII
The Volume of Resting Juice

C.cm.	-40	40	60	80	100	120	160+
Gastric ulcer ..	27	25	19	12	4	2	1
Duodenal ,, ..	6	37	28	9	8	1	9
—	33	62	47	21	12	3	10

44 per cent. of the gastric and in 55 per cent. of the duodenal the resting juice was more than 60 c.cm. in volume. This increased volume of resting juice is readily apparent during aspiration, and the ease with which the juice is withdrawn from an ulcer patient contrasts with the frequent difficulty of obtaining 20 c.cm. in a normal person.

Special attention has been paid to the possible finding of achlorhydria. One woman with pyloric stenosis showed achlorhydria on first analysis which was later replaced by a normal acidity. Three women who complained of pains after food and who showed achlorhydria were reported as showing small gastric ulcer craters.

1. Aged 27. Pain after food for 20 months. Small crater reported on the lesser curve. Both the crater and symptoms disappeared. The resting juice volume was 48 c.cm., and histamine resulted in the secretion of 24 units of HCl as well as pepsin (256 units).

2. Aged 40. Pain after food for 8 years. Ulcer crater reported on posterior wall. "Crater" disappeared in one month, but symptoms persist. Achlorhydria to histamine. Resting juice 46 c.cm., pepsin 256 units.

3. Aged 56. Pain after food for 12 months. "Saucer-shaped" crater on posterior wall. Radiological signs and symptoms disappeared in 3 months. Achlorhydria persistent to histamine. Resting juice 54 c.cm., pepsin 256 units.

These brief records have been incorporated to show their unconvincing nature. In only the one with free HCl to histamine was the ulcer crater found in

the usual situation; in the other two it was described as on the posterior wall—an uncommon site. Although the symptoms were apparently relieved by medication in two, it is doubtful whether they should be included as patients suffering from peptic ulcer. In all probability they are examples of gastritis in which the radiological findings are not a little uncertain.

A more interesting example of achlorhydria is that of a man, aged 34, who first appeared complaining of vague indigestion in 1933. A barium meal disclosed no organic disease, but on gastric analysis achlorhydria persistent to histamine was discovered. Some symptomatic treatment was advised and he was well until the beginning of 1935. Pain, but of a more definite character and periodicity, returned. A further barium meal now showed a lesser-curve ulcer, and when a second gastric analysis was done a normal acid secretion was found. The crater and symptoms disappeared in two months. In this case the appearance of an ulcer crater was associated with the presence of free HCl in a person who previously had shown achlorhydria.

It is generally agreed that a high acidity is more often found in benign ulcer than in any other state. Within recent years attention has also been drawn to the dyspepsia of "nervous origin," in which the gastric secretion is copious in volume and of high acidity—the ulcer syndrome without an actual ulcer demonstrable. The exact mechanism of this hypersecretion is still sub judice. Some investigators attribute it to pyloric spasm and the absence of free alkaline regurgitation from the duodenum, while others believe that the hypersecretion is a manifestation of a constitutional type—the hypersthenic gastric diathesis of Hurst—a more or less permanent state.³⁴ It is very difficult to reconcile success in treatment with a belief in the persistence of hypersecretion and hyperacidity, if we are at the same time to attribute an essential part to gastric juice in the development of ulcer. Ulcers should only heal with difficulty and rarely, but the reverse is true. Is it possible that the hypersecretion and hyperacidity do diminish under certain favourable conditions?

H. = hyperchlorhydria. R J = resting juice. N. = normal acidity.

FIG. 12

The gastric secretion was repeatedly examined over a course of three to four years in 52 of my patients, and it was found that a definite diminution both in acidity and volume was recorded in some of the analyses. The initial examination performed during the first six months of treatment showed the following distribution—hyperacidity in 42 and a normal acidity in 10. During the following four years only 13 showed a persistent hyperacidity, while as many as 39 did at some time or other show a normal acidity. The change occurred at varying periods, but several showed no change in the gastric secretion until the lapse of two years.

We were fortunate enough to obtain several records of some who suffered recurrences, both of symptoms and a return of crater. Table VIII. shows the types of secre-

toms; a recurrent ulcer and hyperchlorhydria, which has now persisted for some six months (Fig. 12).

B.—This man had hyperacidity and a lesser-curve ulcer in 1932, a normal acidity in 1933, and in 1934 a return of symptoms and hyperchlorhydria. He was

FIG. 13

operated on, but the ulcer had healed and a scar was all that was left. In this case both symptoms and hyperacidity returned before the recurrence of the ulcer (Fig. 13).

C.—The third patient, a woman, had a duodenal ulcer with a high acidity in 1932. This persisted at the time of the second analysis and had diminished little twelve months later. We can expect this patient to be a ready prey to recurrence unless greater diminution in resting juice and acidity is recorded (Fig. 14).

D.—In 1933 the fourth patient had a duodenal ulcer with a characteristic acid secretion. Sixteen months later the acidity was much lower (Fig. 15).

FIG. 14

tion and the volume of resting juice in recurrent duodenal and gastric ulcers. Four examples may be given.

A.—This man showed hyperchlorhydria and a gastric ulcer in 1930, a normal secretion and no radiological abnormality in 1931, and in 1934, with a return of symp-

The number of repeated analyses is small, but nevertheless I think the results are of some significance. Under favourable conditions there is a diminution, both in acidity and volume, but the improvement may not be manifest for a year or more. Even then it may only be temporary, to be replaced by a hyperacidity with a recurrence.

Is this fluctuation in acidity the reason for the spontaneous remissions and the long lasting relief from symptoms in people who have had the most inadequate treatment?

The return of hyperacidity in a recurrence is again in keeping with the experimental work on the importance of an active concentrated juice in the production of ulcer in animals.

The Emotional Factor

In the initiation of the ulcer lesion are we to believe that the nervous system plays an important

FIG. 15

part? We know that symptoms often precede ulcer development, and we know that such periodic symptoms are not uncommonly found in people under tension.^{34 35} The relief of the tension often brings silence in the abdomen. Can we—in a significant proportion of cases—recognise some such mental upset in the life of the individual preceding ulcer development and preceding a recurrence? From the experimental evidence it would be fair to presume that a deep emotional upset would be just as capable of stimulating the hypothalamic centre as would the more artificial electrical stimulation, which we already know is capable of producing hyperperistalsis and hypersecretion. Continued stimulation might be responsible for gastric erosions, hæmatemesis, and even ulceration.

The constitutional type has been well described by a number of observers (Hurst,²¹ Ryle,³⁶ Draper,³⁷ Rivers³⁸). Robinson³⁹ has recently described the man with ulcer as being in the firing-line of life's struggle, and Draper has convincingly shown that the ulcer patient is of a different mould to him with a gall-bladder lesion. The angularity of the body, combined with the dynamic energy, is characteristic. He works under tension with vigour and enthusiasm, and he is generally under-weight, an increase in weight being always a sure sign of improvement not only physical but mental. He is fully conscious of his responsibilities, but is reticent to the unfolding of his difficulties and anxieties. He certainly does not like to attribute his disturbed gastric function to his nervous system, although he often relates that during week-ends and other periods of relaxation his stomach is surprisingly silent.

The majority of my patients were under-weight. Table IX. shows that 60 per cent. were under 9 st. and 34 per cent. under 8 st. on their first appearance. It is difficult to assess and describe the various

influences which might possibly affect an individual, and a mental upset in one might be of little consequence in another. An attempt will be made to give an account of nervous influences more by example than by any general description.

NERVOUS UPSETS BEFORE THE DEVELOPMENT OF
DYSPEPSIA

I.—A man of 33, the father of six children, obtained work after a long period of unemployment. He was considerably upset three weeks later when he was forced to keep to his bed with influenza. In a few days he was well and he returned to work, but became greatly distressed to find that his post had been filled. Five days later he showed a perforated ulcer.

II.—A man, aged 53, who had always enjoyed excellent health, and who had been employed as chauffeur for many years, with the customary long hours of waiting, was favoured with a legacy on the death of his employer. He opened a small business and was soon troubled by financial anxiety. For the first time in his life he developed indigestion, and in ten days' time had a severe hæmatemesis. The presence of a peptic ulcer was subsequently verified by a barium meal. In this case the man had been accus-

tomed to security and served in a position somewhat free of hazard. Launching out into independence at 53 years of age resulted in mental anxiety and this was accompanied by the development of an ulcer.

III.—A woman of 49 had always enjoyed perfect health until she witnessed her daughter run over by a motor-car. Five days later she complained of indigestion. In a month's time a crater was visible in the duodenum.

IV.—A man of 48 suddenly lost, through death, two brothers who were partners in his firm. There was much financial worry in consequence and he began to suffer from severe indigestion. He was seen five weeks after the development of dyspepsia, and a large ulcer (Fig. 16) was discovered on the lesser curve. He had previously enjoyed excellent health.

NERVOUS UPSET AND RECURRENCES

During the last five years I have seen 45 recurrences, and doubtless this number will increase as the periods of observation extend. In 20 of these patients I have definite knowledge of some mental upset preceding the return of symptoms, and this is a sufficiently high proportion for us to seriously consider whether a deep emotional upset is not capable of producing a recurrent ulcer. Table X. shows the time of recurrence, and the nature of the upsets which preceded it, in the gastric and duodenal ulcer patients. Examples of the influence of mental upset in recurrence are the following:—

1.—A male, aged 45, was the manager of a failing business in 1931. The failure became a reality and he developed

indigestion. An ulcer was found on the lesser curve and treatment brought relief. He was well and working in a less responsible position until early in 1934, when his only child was diagnosed as suffering from pulmonary tuberculosis. This caused much upset and anxiety at home and his symptoms returned. A large ulcer crater was discovered and treatment again brought relief. The crater disappeared in six weeks and he gained weight from 9 st. 6 lb. to 10 st. 8 lb. during the following six months. Everything appeared well, and periodic radiological examination showed no return of the ulcer crater. However, in August this year he was again, owing to the holidays of other members of the staff, put in sole charge of a firm. Work was heavy and he was uncertain whether he could cope with it. Dyspepsia returned and a large crater became visible on the lesser curve of the stomach.

2.—Another patient, who had responded well to treatment, had in his sixth month the misfortune to lose his wife, after an operation. His grief was profound. Pain returned and an ulcer crater became again demonstrable and larger in size than on the initial examination. He died from a hæmatemesis in the seventh month. In this case there were undoubted signs of healing, but even with complete rest in bed and the strictest medical attention, the sudden grief was followed by a recurrence and a hæmatemesis closed the scene.

NERVOUS INFLUENCES IN POST-OPERATIVE RECURRENCES

Surgery does not of necessity confer an immunity against recurrences. Of the 15 patients who showed active ulceration some years after the initial operation for ulcer, 8 gave details which strongly suggest the important part played by nervous upsets. Table XI. gives the salient features, but two of the cases are worthy of more detailed record.

TABLE XI

Nervous Influences in Post-operative Recurrences Operation.—Gastro-enterostomy for duodenal ulcer

Age.	Date of op.	Present findings.	Remarks.
44	1927	1929. Recurrence of symptoms; medical treatment. 1932. Perf. jejunal ulcer. 1932. Partial gastrectomy. 1935. Recurrence of symptoms; ulcer crater lesser curve.	— — Four mths. dyspepsia on notice to leave work, held for 21 years.
47	1927	1935. Large ulcer, lesser curve.	Business worries; failure to negotiate sale of failing business.
58	1928	1934. Duod. ulcer crater and jejunal crater.	Wife ill, heart failure, much anxiety; hæmatemesis.
34	1927	1934. Jejunal ulcer.	Hæmatemesis on dissolution of partnership.
54	1929	1934. Lesser curve ulcer.	Death of wife. Four mths. dyspepsia.
30	1931	1935. Duod. crater.	Family quarrels.
40	1934	1935. Perf. jejunal ulcer.	Sudden illness of mother; return of dyspepsia.
43	1931	1934. Duod. deformity only.	Son in motor accident; return of symptoms.

A.—A male, aged 34, had a gastro-enterostomy performed for a perforated duodenal ulcer in 1927. In 1928 he suffered a mild recurrence of symptoms, but he enjoyed very good health afterwards until there was a sudden hæmatemesis in 1933. The anæmia was intense and his condition gave rise to much concern. In September of that year it was shown that he had a jejunal ulcer as well as an active duodenal ulcer. Treatment improved his general condition and in the early part of 1934 a barium meal demonstrated the disappearance of the jejunal crater; but one of the jejunal loops was found to be dilated and barium was held up in this loop for an appreciable time. A lateral anastomosis of the jejunal

loop was performed, and this operation gave an opportunity to verify the disappearance of the jejunal ulcer. A further barium meal a month after the operation showed the anastomosis between the two loops to be working well. The patient affirmed that he never had been fitter. He returned to work after a brief holiday and received what he termed the greatest shock of his life when the other partner in his firm said that a dissolution of partnership was imperative because he, the patient, had been

FIG. 16.—Large ulcer crater in a man of 48 with a five weeks' history.

away too much from business. Seven days later he had severe hæmatemesis.

B.—A man of 44, for whom a gastro-enterostomy for duodenal ulcer was done in 1927, enjoyed freedom for two years. A recurrence of symptoms was treated medically in 1929, and in 1932 a jejunal ulcer perforated after five days' dyspepsia. Six months later partial gastrectomy was performed. He enjoyed good health subsequently until 1935, when, following some episode of doubtful integrity, he was given notice to leave his work, where he had been in constant employment for twenty years. Much anxiety resulted as well as considerable disturbance in his domestic affairs. Within seven days indigestion returned and it continued for four months, when a barium meal examination showed that he had a large ulcer crater on the lesser curve of the remaining portion of his stomach.

IMPORTANCE OF THE NERVOUS FACTOR

There are undoubtedly many influences adverse to the healing of an ulcer. Coarse food, long hours without food, smoking to excess, violent muscular work, and especially fatigue from overwork, all play an important part and in all probability recurrences are often due to one or more of these factors. My own belief is that emotional upsets may also be powerful influences in producing a disturbed gastric function, and the incidence of such upsets in the recurrences of my series is especially high, even in those already subjected to operative interference, and in whom we could expect a ready regurgitation of alkaline juice into the stomach. Draper and Touraine⁴⁰ drew attention to the high familial incidence of ulcer, and suggested that there is a weakened or vulnerable alimentary tract which runs in families. Exposure to unusual anxieties or stress would perhaps be sufficient in susceptible individuals to develop an organic gastric lesion. I wish to emphasise that many of the examples which I quote were in persons who had already reached mature years; yet some change in environment or work

or increased responsibility or anxiety appears sufficient to produce alimentary symptoms never previously experienced.

Whatever view is taken of the influence of the nervous system on ulcer development, it certainly calls for a treatment which is wide enough to envisage the whole man and his environment. It becomes a general problem and not a local one. Furthermore, it becomes highly individual, and each case needs

FIG. 17.—Tumour compressing medulla and producing internal hydrocephalus. Three hæmatemeses during twelve months before signs of increased intracranial pressure developed.

specific attention. Steering the patient through a mental crisis or possibly diminishing his responsibilities and thereby lessening stress and strain may do much in preventing a relapse. This close relationship between the organic peptic ulceration and nerve influence furnishes an explanation for the increasing incidence of ulcer in city dwellers. In spite of better food and better hygiene the condition is on the increase, and the greater stress and strain of living to-day can hardly be dismissed.

Organic Nervous Disease

Reference has already been made to the patient who showed a tumour compressing the medulla oblongata, and in whom a bleeding ulcer attracted attention six months before the development of nerve symptoms—an example of an organic nerve process situated in the line of the vagal tracts, a possible cause of the chronic ulcer. A similar case came to my notice in 1933.

A man of 37 had suffered vertigo for 13 months, associated with headache and a staggering gait. Three attacks of hæmatemesis occurred during this period, and two radiological examinations failed to reveal any ulcer. When he came under my notice there was bilateral papilloedema, and he died suddenly two hours after admission to hospital. A soft cystic and hæmorrhagic tumour was situated between the vermis of the cerebellum and the medulla, and there was considerable dilatation of the fourth ventricle, the medulla being much compressed. The tumour was an ependymoma.

This case is of interest in that three attacks of hæmatemesis occurred during the period when the patient's nerve symptoms were extremely mild, and a year elapsed before these symptoms became obvious enough to attract any serious attention. Here is, therefore, another example of an organic nerve lesion giving rise to gastric symptoms. Fig. 17 shows the tumour with the dilated ventricles.

Ambulatory Treatment

It is still held by some clinical observers that rest in bed is an essential part of the treatment of peptic ulcer, although Blackford and Bowers⁴¹ have published reasonably satisfactory results with ambulatory treatment. Hospital accommodation is limited, and during the past five years I have been forced to see what could be done in the way of ambulatory treatment. There is some advantage in this, in that the patient is encouraged to remain at his work. Of 351 gastric and duodenal ulcer patients, I admitted for medical treatment only 37. The period of observation does not extend beyond five years, and whatever claims I make on the treatment it must be at the same time emphasised that only 122 of my cases have been seen for more than three years (Table XII).

TABLE XII
Duration of Observations

Under treatment symptoms disappear extremely quickly, and as Goodall⁴² remarks, the "alkaline smile" is at once apparent. The patient gains in weight, and the ulcer, if it is a lesser-curve ulcer, can be seen to disappear, usually within 2-3 months. From Table XIII. it can be seen that 97 of 130

TABLE XIII

gastric ulcers gave rise to no further symptoms, and 128 of 163 duodenal ulcers showed an equally good response. The total of known recurrences was 45 out of 293, but we can expect as time passes that the number of recurrences will be increased. However, the results reasonably justify ambulatory treatment. Even the recurrences do not show any increased difficulty in healing.

Two of the patients died of hæmorrhage while under treatment; one was a woman in her sixth month of treatment, the other a man in his seventh month. Four suffered from melæna during treatment, but the four recovered.

It is generally conceded that carcinoma develops on an ulcer in not more than 2-3 per cent. of cases. Two of my patients unfortunately died of cancer of the stomach, and in both the lesion was a lesser-curve ulcer; it was originally dispelled by medical measures, but a recurrence at a later date became carcinomatous. One case may be given in detail.

The patient, a woman of 41, gave a five years' history of indigestion. She had a large ulcer crater on the lesser curve of the stomach, which disappeared within six

months of treatment. There was immediate symptomatic relief and a gain in weight from 8 st. 4 lb. to 10 st. 6 lb. Gastric analysis showed hyperchlorhydria and a large volume of resting juice. In the sixteenth month the patient had a return of her symptoms. The ulcer crater again became visible, and on this occasion there was an adjoining area which failed to transmit peristalsis. Alkalis brought no relief and the patient lost weight. The hyperchlorhydria was replaced by hypochlorhydria and altered blood. Operation was advised, but unfortunately secondary deposits were present in the liver.

It is somewhat disturbing to realise that a lesser-curve ulcer can actually disappear, and the patient gain weight and relief from symptoms, and yet in so short a time there may be a recurrence ending in cancer. This should impel us to submit all patients treated for peptic ulcer to periodic X ray examinations, however benign the initial appearance of the ulcer.

One of my patients suffered from a perforated ulcer six months after receiving treatment for a duodenal ulcer, which had apparently healed. Unfortunately I know no more than this, nor of the history which preceded the perforation. Three others developed acute attacks of appendicitis during the first few months of medical treatment, and I cannot help wondering whether the alteration in diet, and the purgation sometimes caused by an alkaline powder, may not light up an appendix which is already in a state of chronic inflammation. The three did well.

It has often been stated that all septic foci should be eradicated as an essential part of medical treatment. There is really little experimental proof for this statement. For the past five years I have deliberately withheld any advice regarding attention to septic foci, and since relief from symptoms and healing of crater occurred in such a high proportion of the patients—most of whom came from the out-patient class among whom oral sepsis is certainly not uncommon—it is difficult to believe that sepsis plays any part in the initiation of a peptic ulcer.

Efficient treatment nowadays involves periodic radiological examination, and it is wise to continue its repetition until a restitution to normal is obtained. It is hardly fair to the patient, while such exact information is obtainable, to continue treating him without such knowledge. The change from hypersecretion to a more normal secretion is also an indication that he is on safer ground, while a persistent hypersecretion and hyperacidity should indicate the need for continued care.

The best therapy should include not only exact knowledge of local gastric affairs, but also the fullest knowledge of the patient. His active coöperation, so essential a feature of successful treatment, can only be realised when he is fully aware of the method of approach and its rationale. Moreover, the influence of his work, his anxieties and worries should be made known to him. Indeed, if a mental storm becomes inevitable, advice to buffer his acid juices all the more thoroughly with frequent feeds and alkalis may avert a catastrophe such as a perforation or bleeding. He should also realise that his stomach is his most vulnerable point, and the possibility of forestalling trouble would not be impossible.

The symptoms which precede ulcer development, and which are so amenable to treatment, should also be recognised. We are inconsistent if we diagnose the person with pain relieved by alkalis, who shows no local lesion, as a mere "functional dyspeptic," with all that this carries, and change our front at a later date when an ulcer has appeared to give the

patient all the care of an "organic lesion." The former is the precursor of the latter, and they deserve the same attention. Prevention of ulcer should be our aim, and to attain this our advice may perforce extend into fields far removed from gastric function.

General Conclusions

Although much is still obscure in the ætiology of peptic ulcer as seen in man, experimental surgery has shown that a chronic ulcer can be readily produced, and that active gastric juice is by itself sufficient to produce this lesion in the intestine. Experiment has also shown that there is a centre high up in the nervous system which, when stimulated, produces profound disturbance, both of motility and secretion, in the stomach, a centre which is undoubtedly influenced by higher levels. There is indeed close agreement on many points between clinical experience and these experimental findings. An attempt has been made in this study to show that a benign ulcer forms and heals rather readily, and that the hypersecretion and hyperchlorhydria—findings which are known to be more common in this condition than any other—do diminish and in time are replaced by a more normal gastric secretion. It has also been demonstrated that bodily rest is not essential for the healing of an ulcer crater, and that this healing occurs in some cases while the patient remains at his work.

The idea that peptic ulcer is a local manifestation of nervous disturbance in susceptible individuals is not new. Von Bergman wrote extensively on this hypothesis in 1914, and the further knowledge that has accumulated during the intervening years has supported this conception. The frequency of nervous bombardment in recurrence and in initiating symptoms is further evidence of the importance of these nervous influences. Efficient treatment must, therefore, be not only highly specific to the individual but also wide enough to encompass the whole man and his environment. As much prominence should be given to a consideration of his anxieties as to his diet.

With the advent and growth of pathology, during the latter part of last century, the profession felt confident in being able to distinguish between functional and organic disease. The line of demarcation was clear-cut. To-day we seem less certain of that demarcation, for the influence of mind over matter is recognised as a powerful force, capable not only of disturbing function but also of producing organic structural changes. Is peptic ulcer the end-result of such disturbance along nervous pathways, and should we not concentrate less on the lesion and more on the man and his surroundings?

May I tender my sincere thanks to my friends and colleagues at the Royal Free Hospital for their unflinching help, especially to Dr. D. Staveley and Dr. U. Shelley.

**SKIN AFFECTIONS
UNDERLYING PRURITUS OF THE
VULVA AND ANUS**

A REVIEW OF THREE HUNDRED CASES

By ELIZABETH HUNT, B.A., M.D., Ch.B.

HONORARY PHYSICIAN TO THE SKIN DEPARTMENT, SOUTH LONDON HOSPITAL FOR WOMEN

THE diagnosis of a skin affection when it is localised on or around the external genitalia and anus may be, and often is, extraordinarily difficult, for the distinctive characters of the eruptions are wont to be modified in this moist warm area, and it is sometimes only by the discovery of typical lesions at other sites that the diagnosis can be made with confidence. The need for accurate diagnosis, and for the differentiation of the various skin affections which may give rise to vulval and anal irritation must be apparent, not merely for the purposes of treatment but also for the reassurance of the patient and for guidance in avoiding recurrences.

In Table I. the 300 cases on which this brief review is based are classified into seven groups.

TABLE I

Analysis of 300 Cases of Pruritus into Seven Groups

Cases.	Cases
I.—GENERAL SKIN AFFECTIONS :	V.—GENERAL CONSTITUTIONAL DISEASES :
Lichen planus .. 105	Diabetes .. 12
Seborrhœic dermatitis .. 69	Secondary anemia .. 2
Psoriasis .. 17	Disseminated sclerosis 1
Eczema .. 2	
Leucoderma .. 4	VI.—PSYCHIC .. 8
II.—DERMATITIS TRACMATICA ET VENENATA 59	VII.—VARIOUS :
III.—LOCAL CAUSES :	Lichenoid eruption with oral sepsis .. 2
Vaginal discharge .. 3	Lichenoid eruption with cholecystitis 1
Vaginal prolapse .. 2	Lichenoid eruption with malignant neoplasm of liver 1
Hæmorrhoids .. 2	Senile pruritus .. 2
IV.—PARASITES :	Imperfect hygiene .. 2
Scabies .. 2	Undetermined .. 3
Ringworm (Dhobie itch) .. 1	

The most striking feature of the Table is probably the large number of cases recorded as suffering from well-recognised skin affections, and in particular the excessive proportion of cases of lichen planus—an eruption which may affect skin and mucous membrane, and which is usually stated to occur rarely on the vulva.

LICHEN PLANUS

In a recent article¹ I have drawn attention to the similarity both in the clinical and histopathological findings between eruptions of lichen planus on the vulva and the condition commonly called leuco-

plakia vulvæ, which, it is stated, affects the skin of the vulva and of the adjacent parts. Many of the cases here classified as lichen planus of the vulva were referred with the diagnosis "leucoplakia vulvæ," and the existence of lichen lesions at other sites had not been observed.

The type of leucoplakia known as leucoplakia vulvæ, which it is stated affects ordinary skin, differs both in its clinical and histological findings, and must be carefully differentiated from the affection of mucous membrane known as leucoplakia buccalis, which occurs more commonly in men, and to which a sinister significance is attached owing to the records of cases in which malignant changes have been reported.

The importance of the observation that lichen planus of the vulva is indistinguishable both clinically and histologically from what is commonly described as leucoplakia vulvæ, lies in the fact that it is generally taught in the English text-books of gynaecology that leucoplakia vulvæ is a precancerous condition of the skin, and the serious operation of vulvectomy is advised for this condition, even in the absence of definite evidence of malignant change. Lichen planus is on the other hand definitely not a precancerous condition of the skin, so that the outlook for the patient must be widely different if a diagnosis of lichen planus rather than of leucoplakia vulvæ is established.

Confirmation of a diagnosis of lichen planus often requires the observation and consideration of lesions widely remote from one another, and in the cases here submitted a diagnosis of lichen planus of the vulva was made with extreme reserve unless typical lesions of lichen planus were evident at other sites. The search for lesions at different sites necessarily involves a general examination of the patient, and the study of these cases suggests a need for such an examination in every case where itching of the vulva and/or anus is the chief complaint.

The manifestations of lichen planus of the vulva are more fully discussed in the article to which reference has been made above.

SEBORRHŒIC DERMATITIS

The number of cases of seborrhœic dermatitis in the series is also high, and seems to indicate that seborrhœic dermatitis as a cause of vulval pruritus merits more consideration than is usually accorded to it. These cases included the youngest patients in whom vulval pruritus occurred, as might be expected, since the skin of the seborrhœic patient is peculiarly liable to develop eruptions from infancy upwards, and reacts to a great variety both of exogenous and endogenous causes by which the normal person is unaffected. Hence in such cases the general skin history needs investigation as well as the local condition, and it is to be remembered that the skin in these patients may be adversely affected by the usual anti-pruritic applications or even by such apparently innocuous causes as the bases of the ointments applied. Eruptions in seborrhœic patients are frequently associated with emotional crises, and it is not unusual to find subjective symptoms out of all proportion to objective signs, and as a result the condition in these patients is often extremely intractable.

The eruption is rarely limited to the genitalia. Seborrhœa of the scalp and trunk are usually present and lesions are common on the area covered by pubic hair. The eruption may be asymmetrical and one labium will be found thickened and erythematous, whilst the other is unaffected.

PSORIASIS

Psoriasis as a cause of vulval pruritus is not common. In all the cases here recorded the eruption was of old standing and very limited in its distribution. The lesions were never found on the internal surfaces of the labia, and seldom presented the familiar silvery scales of psoriasis but tended to the exfoliative type. Symptoms were noticeably aggravated by any mental anxiety or disturbance. One case in which excessive subjective symptoms were a feature may be quoted. In this patient a coalescent band of psoriasis lesions was situated on the outer borders of the external surfaces of the labia majora and extended over the mons. Elsewhere only the nails were affected. This patient was the subject of excessive mental anxiety and worry, and vulvectomy had been suggested, on account of the persistent vulval irritation, on an analogy with the treatment advocated for leucoplakia vulvæ when the symptoms prove intractable.

The contrast between the number of cases of lichen planus of the vulva and psoriasis of the vulva in this series merits some comment, because the total number of cases of psoriasis and of lichen planus attending the hospital clinic is approximately the same, constituting about 12-13 per cent. of the total number of cases of every type of skin affection. Of these cases of every type the proportion with vulval symptoms is unusually high for a general hospital clinic, but may be accounted for by the fact that the hospital is entirely officered by women, to whom such cases would naturally gravitate.

ECZEMA

Eczema as is to be expected was a common diagnosis in cases referred to the clinic, but the two cases included under this heading seemed to me the only two in which a diagnosis of eczema could be made with assurance. Both patients were young married women with children; both had extensive weeping eruptions over the abdomen, genitals, and thighs; one had, in addition, an eczema of the hands, the second developed an eczematous rash on the arms and trunk following a slight excess of sweets. No trace of glycosuria was detected in this case at any time. The patient had undergone intensive treatment for months, including X rays, without relief until she was put on a mildly restricted carbohydrate diet, when the condition rapidly cleared and she has had no recurrence for two years.

LEUCODERMIA

The cases of leucoderma showed transient patches of de-pigmentation on the labia with a slightly inflammatory border to the lesions, and associated with intense irritation. No cause could be detected and no other skin lesion was observed.

DERMATITIS TRAUMATICA ET VENENATA

The cases grouped under the title dermatitis traumatica et venenata include all those in which the eruption was traced to injury inflicted by deleterious applications, and those others in which an individual hypersensitiveness to some particular external cause could be traced. In most of these cases both the anus and vulva were involved, as might be expected, since the usual history obtained was of a slight initial irritation of the vulva or the anus, which had become steadily worse and spread as the patient used one remedy after the other. In some the lower abdomen, buttocks, and thighs were the site of an acute inflammatory eruption; others

showed a white dry harsh skin inclined to fissure and similar to the conditions seen on the hands as the result of the excessive use of alkalis and antiseptics, whilst in others there was marked lichenification of the vulva and adjacent surfaces.

The cause of the initial irritation was often difficult to determine. Idiosyncrasy in some cases was the factor, as when the onset followed vaginal douches of iodine, or coincided with the use of a particular soap, or with an alteration in underclothing such as the adoption of dyed artificial silk undergarments or of the tight woollen garment known as "panties." A history of recurrent irritation at the menstrual period was not infrequent either as a result of the type of pad used or from inability to change frequently.

Where the irritation first arose around the anus, hæmorrhoids and constipation were a common finding, but hæmorrhoids per se will not cause an acute dermatitis of the vulva, nor on the other hand will a vaginal discharge or vaginal prolapse directly affect the skin of the anal area. The associated dermatitis in these cases is more commonly the result of frequent applications of different kinds which injure the skin.

Table II. shows the causes which were found to have contributed to the production of eruptions with persistent irritation in the cases under review.

TABLE II.—Causes

These figures suggest that an excess of cleanliness and the indiscriminate use of antiseptics, rather than the lack of personal hygiene, are potent causes of vulval and anal pruritus in women to-day, and it is perhaps significant of the changes in social conditions that no case of pubic lice was observed in a series of 300 cases of vulval and anal irritation in women, a majority of whom were seen in hospital clinics.

With regard to aperients the leakage of liquid paraffin around the anus is a fruitful cause of anal pruritus; bile beans is a secret remedy, and it is not therefore possible to explain why it should be the cause of anal irritation. Feen-a-Mint and Ex-lax both contain phenolphthalein, to which these patients were intolerant, and the eruption and irritation in these cases was not entirely restricted to the genital area.

GENERAL CONSTITUTIONAL DISEASE

Of the remaining groups the largest number of cases appear under general constitutional diseases. It is common knowledge that vulval pruritus may be associated with glycosuria, and routine examination of the urine is therefore essential.

The two patients with a secondary anæmia suffered from folliculitis, which cleared up with treatment of the general condition. The case of disseminated

sclerosis is of some interest because the patient had been given X ray treatment for the persistent irritation, though there was no evidence of any skin affection and the symptoms were probably the result of changes in the sensory nerves.

PSYCHIC

Eight cases only have been included in the psychic group though the existence of a psychic factor was recognised in many cases in addition to the definite causes which were found.

The patients included in this group showed no skin changes. One of the patients had become a syphilophobe after the discovery of her husband's infidelity. A second, a young married woman, was referred after she had been treated for months for acute recurrent vulval irritation and insomnia, and it was discovered that for a long time she had a child in hospital with bladder and kidney trouble. It was suggested to her that her thoughts were in consequence concentrated on her own genital area, and that she must cease thinking of it, and within two weeks her condition was relieved and did not recur.

METHYLENE DICHLORIDE INTOXICATION IN INDUSTRY

A REPORT OF TWO CASES

By HOWARD COLLIER, M.C., M.B. Edin.

READER IN INDUSTRIAL HYGIENE AND MEDICINE IN THE
UNIVERSITY OF BIRMINGHAM

Methylene dichloride (CH_2Cl_2) is a chlorinated hydrocarbon of relatively low flash-point, widely used in modern industry as a solvent for cellulose esters, fats, oils, resins, and rubber. It forms a large proportion of certain proprietary "paint removers," some of which are of German origin, and has also been used in the paint trade to raise the flash-point of lacquers.

It is an anæsthetic with a pleasant chloroform-like smell, slightly more toxic and irritant than chloroform. In commercial use it may be contaminated by the presence of methyl chloride (CH_3Cl): this sometimes might complicate the clinical picture. It was formerly used as a general anæsthetic by Richardson (1867); "10 fatal cases resulting from its use as an anæsthetic have been misquoted as due to its use in industry." "Otherwise no definite cases of poisoning have been reported," and Zernik¹ sums up the existing opinion concerning methylene dichloride when he says that "with good ventilation its industrial use is practically harmless."

In contrast, however, to this opinion may be set the practical experience of a manufacturer of lacquers who informs me that so far as possible he has abandoned the use of methylene dichloride "because of its ill-effects" upon the workers. "It dopes them, makes them stupid, they suffer from headache, are unreliable at their work and are awfully apt to tumble about and to hurt themselves." The same observer remarks upon the curious effect of this solvent and of other solvents upon the "psychology" of the workers. He says that "they are irritable, unhappy and require constant supervision if they are to be kept from making silly mistakes."

This shrewd observation, coupled with the effects of the drug upon the cases recorded below, raises a point of the utmost importance in industrial hygiene. Whilst it may be admitted—may even be proved—that many of these solvents do not (if pure) cause any

discoverable industrial disease, nevertheless they may detrimentally affect industrial health. As typical examples of this class of "physiological, non-disease-producing toxins" we may take methylene dichloride or trichlorethylene (which resembles it in very many of its pharmacological properties). It seems to me that this is a point of the first importance to industry. Workers who are constantly exposed to concentrations of these solvent gases may be rendered inefficient in their work without the production of discoverable pathological lesions.

These cases serve to illustrate another problem which always faces the industrial physician. That problem is the almost invariably "mixed" nature of industrial diseases (Alice Hamilton²). It will be observed that the first of the cases recorded below showed definite signs of chronic lead absorption, whilst the other suffered from a definite peptic ulcer and had recently fractured his skull. It is more than probable in fact that, but for these added disabilities, the connexion of methylene dichloride with the illness from which these workers suffered would never have come to the notice of any medical man.

THE CASES

Four painters were engaged during the autumn of 1935 in removing paint from the wall of a large room. A paint remover containing a high percentage (96 per cent. approx. by analysis) of methylene dichloride was used for this purpose. The windows were closed and rapid evaporation of the solvent took place. In this work the "remover" softens the old paint which is subsequently scraped off the wall by hand. All of the workers had been more or less exposed to lead absorption for periods varying from 5-14 years. They complained that whilst at work with the "paint remover" they became faint, giddy, and stupid, and stated that "this stupor passed off after a few hours," that they "felt better when not at work," and that "the stuff upset their appetite; that they did not care for food"; and that they felt dull and were not interested in things which had always interested them before. Of these four men, two were sufficiently ill to have to leave their work. They were examined by me at repeated intervals.

CASE 1.—A man, aged 42 (a painter for 13 years continuous), first seen on Oct. 12th, 1935. Peritonitis at 12 years of age. Five years' army service; double pneumonia and empyema at 32. Complaints: (a) irregular but severe pains in legs and arms, hot flushes, headache, vertigo, stupidity whilst at work with paint remover; could not read at night because his eyesight was not clear (? transient diplopia); anorexia; (b) precordial pain, rapid pulse, shortness of breath, great fatigue on exertion, and attacks of rapid beating of heart.

On examination soon after a day's exposure to the "remover," a faint "chloroform odour" could be detected in the breath. He was pale and nervous in manner, would flush up over the face and neck and then go pale again. Heart: apex-beat diffuse, outside nipple line. Pulse-rate 108 at rest. Arteries palpable, tenuous. B.P. 130/90. Respiratory system: old empyema wound on right side. No abnormal physical signs in chest. Urine normal. Alimentary system normal. Nervous system: no distinct abnormality. Special senses: no anæsthesia or alterations of sensation discovered. Romberg sign absent. No muscular weakness of hands or wrists. Fundi showed clear evidence of arterio-sclerosis of fundal vessels. Blood: red cells, 4,910,000; white cells, 6200. Normal differential count, but a punctate basophilia of the order of 3500 per million. Punctate granules large.

Course of illness.—Six weeks later the general condition was much improved and he had put on 1½ st. in weight; he still complained of precordial pain, but there was less dyspnoea. During this time the only change in his

circumstances were (a) the cessation of work with the methylene dichloride, and (b) the taking of half a pound of liver a day together with a mixture of ferri et quin. cit. He now looked much better and carried a better colour: pulse-rate 72 (at rest); apex-beat more distinct; heart still dilated; blood pressure 120/86. Blood picture normal, no punctate cells observed. The condition of the fundal vessels was unaltered. He was now quite "alert and clear in his mind." His eyesight was "better." Subsequent examinations at intervals up to the time of writing show that his condition now remains unaltered except for a slow improvement in his general condition.

The conclusions which I draw from this first case are (a) that the patient is suffering from the effects of slight chronic lead intoxication, which is shown by the state of his cardiovascular system, and (b) that he was suffering at the time of the first examination from the effects of acute toxæmia from methylene dichloride. The rapidity with which the acute symptoms subsided and the exact correspondence between his subjective complaints and those of the other workers is too clear to be explained by chance; the condition cannot be attributed (in my experience) to lead. The symptoms resemble also those presented by workers who are exposed to the vapour of trichlorethylene, and in a less extent to other industrial solvents of this non-disease-producing class.

CASE 2.—A man, aged 45, a painter for 20 years. Examined on Jan. 19th, 1935. Pneumonia at 38 years of age. Severe fracture of skull at 40. Irregular attacks of gastric pain and "black stools" since he was 33. Has had "gastric ulcer" on and off for last four years. Has used the same proprietary "paint remover" for two years; recently has used it much more extensively and used it indoors. This work makes him "drowsy, disinclined to do anything in evenings; makes him very irritable and easily disturbed by trifles." "Has pains in the head." He is highly intelligent. He finds that "he is better if he stays away from work." He has noticed "a definite tingling in hands and feet after working with this paint remover." Has now been away from work for two weeks.

On this evidence the patient was admitted to the General Hospital, Birmingham, under Dr. Stanley Barnes, for observation and the treatment of peptic ulcer. It does not appear necessary to detail his clinical condition which was that of a typical case of peptic ulcer, except to say that a congenital opaque patch was found in right disc. Central nervous system: normal. Urinary system: normal. Van den Bergh reaction: direct and indirect negative. Blood count: hæmoglobin, 100 per cent.; red cells, 5,320,000; white cells, 5500; no punctate basophilia; differential count normal. Wassermann reaction negative. Blood pressure 130/75. Pulse-rate 80. Heart and lungs normal. Alimentary system: "gastro-duodenal ulcer."

The condition rapidly improved on Hurst's diet, and he was discharged from hospital on Dec. 3rd, 1935.

The conclusions drawn from this case are that the patient had suffered from the effects of methylene dichloride intoxication on and off for two years until the condition of his alimentary system forced him to leave work. The methylene dichloride poisoning caused definite and characteristic symptoms which were relieved by the cessation of exposure and which are remarkably similar to those detailed above.

It did not prove possible to persuade the other workers to submit to examination, but I have definite information that they experienced exactly similar effects. As their general health was good, they did not leave work.

CONCLUSION

To sum up therefore, these cases suggest that methylene dichloride is a potential source of ill-health to those who are exposed to the fumes of it in any confined and unventilated space. Those effects are to be attributed to its anæsthetic action upon the

nervous system and are largely subjective—viz., headache, giddiness, stupor-irritability, numbness and tingling in the limbs, and possibly some degree of chronic anæmia. It seems to be important to emphasise that many of the industrial solvents (beside the chlorinated hydrocarbons) whilst they may not cause "occupational disease" may be real factors in the production of lowered efficiency, industrial fatigue, and definite psychological abnormalities of feeling and of conduct. It appears that this valuable industrial solvent (methylene dichloride) can safely be used in industry provided adequate ventilation is maintained.

I must gratefully acknowledge the help of Dr. Stanley Barnes, dean of the faculty of medicine in the university, and of Dr. Ethel Browning, of the Medical Research Council, who has put at my disposal much information and many references concerning the known effects of methylene dichloride. I must express also my thanks to Dr. J. A. Ainscow for permission to see the second patient and for his help in providing me with a remarkably detailed history.

INTRASPINAL INJECTION OF ALCOHOL FOR INTRACTABLE PAIN

By W. RITCHIE RUSSELL, M.D., F.R.C.P. Edin.

ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH

IN operations for the relief of neuralgic pain it has been found that complete interruption of the nerve concerned is not necessary, but that partial destruction of the nerve-root has the same good effect. This led Dogliotti¹ in 1930 to attempt to damage the posterior nerve-roots within the spinal canal with alcohol in such a way that the conduction of pain would be arrested while little or no sensory loss would result. After demonstrating the practicability of the procedure by animal experiment he injected small quantities of absolute alcohol—0.2 to 0.8 c.cm.—into the cerebro-spinal fluid of patients suffering from painful diseases. As alcohol has a specific gravity less than that of the spinal fluid, he arranged the position of the patient in such a way that the nerve-roots he wished to affect lay at the highest point of the subarachnoid space as near as possible to the site of injection. For example, if he wished to affect the sacral nerve-roots, he made the injection into the lumbar theca while the sacral region was at a higher level than any other part of the spine or head. Dogliotti used his method in the treatment of conditions such as intractable sciatica and tabetic crises, and reported good results in a high proportion of the cases treated. Others, including Stern,⁵ Saltzstein,³ Yeomans,⁶ Greenhill and Schmitz² have used this method for the relief of the pain of malignant disease, particularly of the pelvic viscera, and have all reported many satisfactory results. During the past eighteen months I have used this method in attempting to relieve severe pain in 18 cases, and in several of these the result of the injection has been satisfactory.*

* Since this paper was written I have treated 4 further cases, in 3 of which the result was satisfactory. Good results following this method of treatment have also been reported again by Greenhill and Schmitz (*Amer. Jour. Obst. and Gyn.*, February, 1936, p. 290), who find it superior to pelvic sympathectomy in cases of carcinoma of the cervix; and by Abbot (*Amer. Jour. Surg.*, February, 1936, p. 351).

DANGERS OF THE INJECTION

It is in the first place necessary to emphasise the dangers of the injection. The most suitable cases for treatment are those in which the pain is referred to the lower part of the body. The injection is, therefore, made into the lumbar theca, and there is a danger of damaging the nervous control of the sphincters. Further, it should be noted that in many cases of pelvic cancer the bladder control is already interfered with by disease, and very slight damage to the nervous control may cause retention of urine. In one such case in the present series the injection of 0.8 c.cm. of absolute alcohol produced retention of urine. Sloane⁴ reports a case in which the injection of 1.0 c.cm. caused the same complication.

A second possible danger is that while the injection apparently causes no damage to the spinal cord at the time of the treatment, slight damage may occur which will cause a tendency to degenerative changes at a later date. In view of our ignorance of the ultimate effect of the injection it seems desirable at present to use the treatment only for advanced cases of inoperable malignant disease. This is the view held by most of those who have used this method, though Dogliotti originally injected many cases of non-malignant disease. It must, however, be noted that Dogliotti used small injections (0.2 to 0.8 c.cm.), and it is probable that injections of 0.4 c.cm. or less can be given safely in any case.

Most of the cases here reported have been of advanced malignant disease, and in some of these injections of as much as 1.5 c.cm. have had to be given in order to give relief from pain. In several cases this amount has been injected without any loss of sphincter control resulting, while in others a much smaller quantity has caused retention of urine. It is thus evident that the individual susceptibility to alcohol injections is very variable. The safest method, therefore, of giving the treatment is to start with a small dose of, say, 0.4 c.cm. of absolute alcohol, observe the effects, if any, during the ensuing ten days, and, if necessary, repeat the injection using a larger amount as is described later. If, in cases of advanced malignant disease of the pelvis, the bladder is drained by a suprapubic tube, and there is a colostomy, the danger of causing sphincter disturbance is removed and a larger injection can be given at first (0.8 c.cm.) without anxiety, provided the technique described is rigidly adhered to.

TECHNIQUE FOR THE RELIEF OF SACRAL PAIN

In order to relieve any pelvic or other pain conducted through the sacral nerves, the sacrum must form the highest part of the spinal canal during, and for a period following, the injection. Further, the side of the body in which most pain is felt must be uppermost. The patient lies in the usual position for lumbar puncture (Fig. 1), while the operating table is tilted or the foot of the bed is raised so that the sacrum forms the highest part of the spine; a pillow may be placed below the pelvis. It is important that the head should always be kept at a definitely lower level than the spine so as to avoid any risk of the alcohol running up into the skull while it is still in a concentrated state. For this injection I prefer to make the spinal puncture between the third and fourth lumbar vertebræ. A few cubic centimetres of spinal fluid are allowed to escape, and then 0.4 c.cm. of absolute alcohol is slowly injected, the whole amount being introduced during

a period of about 20 seconds. Cerebro-spinal fluid should *not* be drawn into the syringe prior to injection. The needle is then withdrawn, but the patient is made to lie in the same position for about an hour. He must on no account raise his head or the upper part of his body. He may, however, with advantage, turn slightly on his face as soon as the injection is completed so that the alcohol may have access more to the posterior than to the anterior nerve-roots. After lying in the same position for an hour, the patient is treated as after an ordinary lumbar puncture. Headache followed the injection in only one of my cases.

During the injection the patient often experiences a burning sensation referred to that part of the body supplied by the nerve-roots that are being damaged by the alcohol. Where the sacral roots are being treated numbness is often noticed in the buttock and foot of the side that is uppermost. Some sensory loss may be demonstrated in the sacral and lower lumbar distribution, and the ankle-jerk is often diminished or abolished.

The degree of sensory loss should be tested shortly after the injection, for this demonstrates not only which nerve-roots have been damaged, but also the degree of damage caused. As has already been mentioned, the susceptibility of the nerve-roots varies from case to case. Within a few hours the slight sensory loss and reflex disturbance usually disappear entirely. In some cases the pain disappears at once. In some it remains unchanged for several days and then ceases, perhaps ten days after the injection. In some it becomes less, but is not abolished. If the pain is still severe ten days after the injection, the operation may be repeated. If the previous injection caused no sphincter difficulty and little sensory disturbance, 0.6 to 0.8 c.cm. of alcohol may be safely injected. As before, the side to which most pain is referred should be uppermost, but if the pain is central, as in the case of bladder and rectal pain, the second injection should be made with the patient lying on the side opposite to that on which he was placed for the first injection. The effect is again observed for a period of ten days, and if pain is still severe, and if there has been no sphincter difficulty, and little or no permanent sensory loss, a still larger injection may be given of 1.0 to 1.3 c.cm. of absolute alcohol. Additional or larger injections are seldom required. After the treatment distension of the bladder should always be looked for and promptly relieved by catheterisation. In most cases in which sphincter difficulty occurs, the difficulty passes off in a few days. The injection for the relief of sacral pain is often effective in relieving the distressing bladder and rectal spasms which occur in malignant disease involving these organs. At the same time, the hæmorrhage and discharge which accompanies these spasms become much less. If the pain persists in spite of these injections, the case should be reconsidered from the point of view of the exact situation of the pain. The above method will only relieve pain conducted via the sacral nerves, and will therefore not relieve pain felt in the front of the thigh or leg, or in the lower abdomen, which is conducted by the lumbar and lower dorsal roots respectively.

METHOD OF RELIEVING LUMBAR OR THORACIC PAIN

When severe pain is referred to a part of the lower extremity supplied by the lumbar nerves, the position of the patient for the injection should be such that the upper lumbar vertebræ form the highest part

of the spine (Fig. 2). The injection may be made between the second and third lumbar vertebrae. The procedure is otherwise the same as described above.

When the pain is referred to the abdomen or chest, the injection is not so easy to carry out. The patient is placed so that the nerve-roots conducting the pain are situated at the highest part of the spine (Fig. 3). The spinal theca is punctured at this level, care being taken to penetrate the theca the least necessary distance, so as to avoid risk of injury to the spinal cord.

Dogliotti described a method of injecting alcohol to affect the cervical nerve-roots, but as I have no experience of this I shall not refer to it further.

FURTHER POINTS REGARDING TECHNIQUE

When the larger injections are being made, it is wise to stop for a few seconds after a part of the injection has been given to test for the presence of gross sensory loss or weakness. Such an observation will give the operator some indication of the sensitivity to alcohol of the nerve-roots in the case he is treating.

Some patients with advanced malignant disease are in an emotional and highly nervous state. In such cases I usually give morphine and hyoscine before the injection, the amount depending on the tolerance already developed for the opiates.

RESULTS OF THE TREATMENT

In the following short abstracts of the cases treated it will be noted that the injections given were in many instances larger than those advised. The first injections I gave were small (0.5 c.cm.) but had no effect in relieving severe pain, hence in advanced cancer cases I have given injections of 1.0 c.cm. or more. As however in one recent case this amount has caused retention of urine, I am again reducing the amount of the initial injection. It should be clearly understood that most of the cases treated have been advanced cases of malignant disease, most

FIG. 1.—Position of the patient for injection when the pain is conducted through the sacral roots of the right side.

of which were in the cancer wards of a hospital for incurables.

CASE 1.—A man, aged 72, suffered from carcinoma of the prostate for which the bladder had been drained by a suprapubic tube. He had suffered severe spasms of pain in the bladder for over two years with almost continual hæmorrhage from the bladder. Two alcoholic injections were made, one of 0.5 c.cm. and a second of 1.4 c.cm. in November, 1934. Considerable relief of pain persisted to death on Jan. 20th, 1935. A striking effect of the injection was the cessation of hæmorrhage from the bladder.

CASE 2.—A woman, aged 77, suffered from carcinoma of the rectum which caused much rectal pain. 1.0 c.cm. of alcohol was injected on Nov. 19th, 1934. No sensory loss or reflex disturbance could be demonstrated on the day

following. Complete relief of rectal pain persisted to death on June 4th, 1935.

CASE 3.—A woman, aged 50, suffered from a huge tumour of the sacrum and a pathological fracture of the femur. 0.6 c.cm. of absolute alcohol was injected in November, 1934, but no relief of pain resulted. The injection was carried out with great difficulty owing to œdema of the back and patient declined to have a further injection.

CASE 4.—A man, aged 60, was seen on Feb. 28th, 1935, suffering from severe pain referred to the front of both thighs which had been gradually getting worse for a period of seven weeks. The pain was very severe on coughing and was aggravated by lying down, so much so, that he had been unable to go to bed at night for some weeks. Great œdema of both legs had developed. On examination there was no motor, sensory, or reflex abnormality. X ray examination showed some abnormality of the tenth dorsal vertebra, which was thought to be due to malignant disease. The patient was rapidly becoming exhausted with the severe pain and required large doses of morphine to give relief. On Feb. 28th 0.5 c.cm. of absolute alcohol was injected with the patient lying on his right side. The cerebro-spinal fluid was yellow and contained 400 mg. of protein per 100 c.cm. The examination of the cerebro-spinal fluid showed no other abnormality except that the colloidal gold curve was

FIG. 2.—Position of the patient for injection when the pain is conducted through the lumbar roots of the right side.

FIG. 3.—Position of the patient for injection when the pain is conducted through the lower dorsal roots of the right side.

333322210000. No relief of pain resulted, and on March 1st 1.3 c.cm. of absolute alcohol was injected with the patient lying on his left side. On the day following there was some difficulty with micturition which subsequently passed off. There was also transient weakness of the right leg and some sensory loss in the sacral distribution. For two days after the second injection the pain remained severe; thereafter, it quickly disappeared and in June, 1935, the patient returned to full work as a sea-captain. When examined on Jan. 18th, 1936, seven months later, he was still perfectly well, free of all pain and able to do full work. The only effect of the injection was slight numbness in the fifth lumbar and first sacral distribution on the right side. X ray examination of the spine showed no conclusive evidence of disease. There had been no further difficulty in passing water and the area of sensory loss was becoming steadily less. The diagnosis in this case remains undetermined.

CASE 5.—This patient, a man of 65, suffers from carcinoma of the rectum. Colostomy was performed in May, 1934, and suprapubic drainage of the bladder instituted in December, 1934. Owing to severe perineal pain 1.0 c.cm. of alcohol was injected in March, 1935. Pain was relieved for two months, after which a further injection of 1.3 c.cm. was given to affect the opposite sacral roots. Slight sacral sensory loss and absence of the ankle-jerk persisted for a few days. Pain was almost entirely relieved and the patient's general condition improved greatly. In November, 1935, he was able to walk half a mile. Thereafter some discomfort returned owing to the progressive reduction of bladder capacity.

CASE 6.—A woman, aged 59, suffered from carcinoma of the uterus which was causing great pain. On March 3rd, 1935, 1.5 c.cm. of absolute alcohol was injected. Transient weakness and sensory loss in one leg resulted. No sensory loss persisted, but pain was relieved till death on May 7th.

CASE 7.—A man, aged 62, suffered from advanced carcinoma of the rectum for which a colostomy had been performed. Severe root pains had been referred to the left thigh for many months causing great restlessness and for which large doses of opium were required. Injection of 1.5 c.cm. of absolute alcohol on April 19th, 1935, abolished the reflexes in the left leg, but caused little motor or sensory loss. No further opium was required and the patient was free of severe pain till he died on May 3rd.

CASE 8.—A woman, aged 53, had a huge sarcoma involving the sacrum and lower lumbar vertebrae. She suffered very severe pain on movement and had been obliged to lie on her face for three months. On May 25th, 1935, with the patient lying on the right side, 2.0 c.cm. of alcohol was slowly injected above the first lumbar vertebra, the lower intervertebral spaces being invaded by tumour. Little pain was felt on the day following and the patient was able to be nursed on her back free of severe pain till she died on July 5th. No retention of urine occurred and little motor or sensory loss resulted.

CASE 9.—A man, aged 66, suffered from severe pain due to rectal carcinoma for which colostomy had been performed. 1.5 c.cm. of absolute alcohol was injected on June 29th, 1935. Some weakness of the uppermost leg occurred with loss of knee- and ankle-jerks and sensory loss below the third lumbar supply. Pain was relieved but death occurred from gastric haemorrhage on July 2nd.

CASE 10.—A man, aged 77, suffered from cancer of the pelvic organs for which a colostomy had been performed. 1.5 c.cm. of absolute alcohol was injected on July 13th, 1935, to damage the left sacral nerve-roots; but no sensory loss, weakness, or reflex disturbance resulted. Great relief of pain persisted till death on July 18th.

CASE 11.—A woman, aged 58, suffered from carcinoma of the rectum for which colostomy was performed in September, 1934. Rectal pain had been becoming steadily more severe and was hardly bearable. On July 29th, 1935, 1.3 c.cm. was injected to damage the left sacral nerve-roots. As some pain persisted the injection was repeated ten days later; on this occasion the right side was uppermost and 1.5 c.cm. of absolute alcohol was injected.

Some weakness and sensory loss occurred after both injections, but pain was entirely relieved and there was no loss of urinary control. The slight weakness did not prevent her from walking without difficulty. The patient left hospital and returned home on Sept. 5th.

CASE 12.—A man, aged 65, suffering from carcinoma of the prostate and severe root pains in the left thigh. On August 11th, 1935, 1.4 c.cm. of alcohol was injected with the left leg uppermost. Considerable sensory loss in the left sacral distribution and complete retention of urine resulted. Severe pain persisted in the second lumbar distribution, but the patient declined to have a further injection.

CASE 13.—A man, aged 66, suffered from advanced carcinoma of the rectum for which colostomy was performed in June, 1935. Recently some urinary difficulty had been noticed. On Sept. 14th 1.0 c.cm. of alcohol was injected. The knee- and ankle-jerk on one side were abolished, but some pain in the rectum continued and the patient complained of a numb feeling of the leg. Further injections were not carried out in view of the urinary difficulty.

CASE 14.—A man, aged 60, suffered from advanced malignant disease of the left lung. There was severe pain referred to the scapula and to the lower part of the abdomen on the left side. On Sept. 26th, 1935, after the administration of morphine and hyoscine to enable the patient to lie comfortably, he was placed on his right side in such position that the sixth dorsal vertebra formed the highest point of the spine. The subarachnoid space was tapped between the seventh and eighth dorsal vertebrae and 0.6 c.cm. of absolute alcohol was slowly injected. This relieved the pain in the left scapula but severe pain continued in the left side of the abdomen. A further injection was given ten days later of 1.0 c.cm. with the eighth dorsal vertebra forming the highest point of the spine. This, however, failed to relieve the severe pain and further injections were not attempted.

CASE 15.—A woman, aged 75, had been incapacitated for the past year with severe arthritis of the knees. On Nov. 30th, 1935, 0.5 c.cm. of absolute alcohol was injected into the subarachnoid space between the third and fourth lumbar vertebrae, with patient lying on her right side and the third lumbar vertebra forming the highest point of the spine. No sensory loss was demonstrated following the injection and the reflexes were unaltered. Some relief of pain in the left knee resulted.

CASE 16.—A woman, aged 48, suffered from an advanced stage of disseminated sclerosis with extreme contracture of the right leg and considerable flexion deformity of the left leg. Flexion spasms of the legs were frequent and caused great pain. On Dec. 20th, 1935, 0.5 c.cm. of absolute alcohol was injected into the subarachnoid space between the second and third lumbar vertebrae, the patient lying on the right side and the third lumbar vertebra forming the highest point of the spine. Almost immediately the clonus of the left ankle and knee was abolished and the spasm at the left knee became much less. The left knee-jerk was abolished. Considerable sensory loss occurred from the second to fifth lumbar distribution of the left leg, the sacral segments escaping entirely. On Jan. 20th, 1936, considerable pain continued in the extremities, but flexion spasms of the left leg no longer occurred. The knee-jerk was still absent and the ankle-jerk was sluggish. The injection had not increased the patient's slight difficulty with micturition.

CASE 17.—A woman, aged 47, suffered severe perineal pain from carcinoma of the vagina which involved the rectum. 1.0 c.cm. of absolute alcohol was injected. Transient sensory loss occurred in the S1 to S5 distribution of one leg. Severe pain was relieved, but the patient remained very uncomfortable and slight incontinence of urine followed the injection.

CASE 18.—A man, aged 68, suffered from carcinoma of the rectum for which a colostomy had been performed. Severe spasms of rectal pain with haemorrhage caused great distress. 0.8 c.cm. of absolute alcohol, injected on Dec. 26th, 1935, to damage the left sacral roots, caused

some temporary sensory loss in the left sacral distribution and loss of the left ankle-jerk. Complete relief of rectal pain resulted, but retention of urine occurred. The rectal discharges ceased.

SUMMARY

1. The intraspinal injection of alcohol is a dangerous procedure unless carried out with great care and strict attention to the details of the technique advised.

2. The injection often relieves the severe pain of malignant disease.

3. Eighteen cases which have been treated by this method are briefly described.

TREATMENT OF ANKYLOSTOMIASIS IN INDIAN SEAMEN

By A. H. WALTERS

SENIOR TECHNICIAN, ROYAL ALBERT DOCK HOSPITAL

Under the direction of

Dr. G. CARMICHAEL LOW and Dr. P. H. MANSON-BAHR

WHILE examining the stools of Indian seamen after treatment for ankylostomiasis, it was noted that although ova-free stools were finally obtained the worms were often never recovered in the faeces. Therefore a small series of investigations were carried out during the years 1930-34 on such patients admitted to the Albert Dock Hospital under the medical charge of Dr. Low and Dr. Manson-Bahr to discover whether recovery from ankylostomiasis could take place without the worms ever being found in the stools after treatment.

All the cases in this series were Indian seamen employed in ships running between London, India, Africa, and the Far East. In each case the number of ankylostome ova per c.cm. of faeces was obtained by the Clayton Lane direct centrifugal floatation method before treatment to obtain an idea of the degree of infection. After treatment each stool passed was examined by the same method and the number of ankylostome ova per c.cm. was noted. Where necessary the treatment was repeated until ova-free faeces were obtained on at least seven consecutive days. After the seventh day if ova-free faeces were obtained, the patients were discharged from hospital to go back to their work on the ships. Between 5 and 12 months later, when the men returned to London, specimens of faeces were obtained from them and examined, as before, for ankylostome ova. The men were treated with various anthelmintics and the Tables illustrate the work done and the results obtained.

Although the patients returned on their ships to tropical countries it is fairly safe to assume that they were not reinfected with ankylostomiasis during their short stay on shore. A number of interesting points may be noted:—

1. In the stools recovered immediately after treatment small fragments of what were thought to be disintegrated worms were found in about 25 per cent. of all cases examined. It is thought that the majority

of these natives contract ankylostomiasis during childhood and that the worms become firmly embedded in the convolutions of the wall of the small intestine. Anthelmintic treatment by the combined method seems to be the most efficacious way of killing these worms, but it does not remove them intact.

TABLE II.—Summary of Results

Table I.	Treatment.	Men treated.	Men in whom worms were recovered after treatment.	Men relapsing after 5-12 months.
A.	Thymol.	8	1	2
B.	Oil of chenopodium.	6	1	2
C.	Carbon tetrachloride.	6	2	2
D.	Combined treatment.	17	2	0

2. Faecal films, prepared by the ordinary coverslip-saline method, of stools containing ankylostome ova do not reveal the eggs as a rule unless the ova content is greater than 60 per c.cm. The Clayton Lane method is undoubtedly the best for detecting ankylostome ova in faeces.

3. The technique of administering the combined treatment is conveniently carried out as follows: (a) starve the patient from midnight; (b) at 9 A.M.

give carbon tetrachloride M 40 in two gelatin capsules and oil of chenopodium M 15 in two gelatin capsules, followed by magnesium sulphate 1 oz. in a tumblerful of water. Natives usually experience no trouble in taking the treatment, but about one in ten are sick after carbon tetrachloride; aspirin, grs. 10, relieves this. Stools are passed at the rate of about three during the first 24 hours, two during the second 24 hours, after which defæcation becomes normal.

4. Although not recorded here, some of the men included in this series were also suffering from *Ascaris lumbricoides*, *Trichuris trichiura*, and *Oxyuris vermicularis* infections. The combined treatment seemed to be satisfactory for these helminths also.

I am much indebted to Dr. Carmichael Low and Dr. Manson-Bahr, under whose direction the work was carried out, and to Dr. H. M. Hanschell for kindly providing laboratory facilities to undertake this work.

TECHNIQUE OF INTRAVENOUS ANÆSTHESIA

BY RONALD JARMAN, D.S.C., M.R.C.S. Eng., D.A.
AND

A. LAWRENCE ABEL, M.S. Lond., F.R.C.S. Eng.

THIS note describes the methods we use for injecting intravenous anæsthetics such as Evipan and Pentothal. As we have lately pointed out,¹ these can be given in one of three ways: as a single dose; in repeated doses; and by continuous intravenous infusion.

1. *Single dose.*—The sterilised syringe having been loaded, a dental prop or Hewer's mouthpiece is inserted between the patient's teeth. The upper part of the arm is constricted, either manually or by a pressure armlet, and the needle inserted into an antecubital vein. Assuming a dose of 10 c.cm., the first 2 or 3 c.cm. of the solution is injected in about 15 seconds, during which time the patient is asked to count. He usually becomes unconscious in 15-30 seconds, and a pause is then advisable, for about the same period, so that one may be satisfied that his condition is within normal limits. If the injection is given too rapidly, the pulse-rate rises and the respirations become depressed. The next 3 or 4 c.cm. should be injected in about 30 seconds. After a further short pause, provided the patient's condition is satisfactory, the remainder of the 10 c.cm. dose is given at the previous rate. Both the pulse and respiratory rates are constantly observed, a clear airway is maintained, and the jaw is supported throughout the anæsthesia.

2. *Repeated doses.*—If a further dose is likely to be wanted the needle may be left in the vein, and the syringe removed, re-charged, and

FIG. 1.—Dickson Wright's apparatus.

replaced if required. For this purpose Dickson Wright's splint,² which controls the forearm, will be found convenient. This has an upper band consisting of a pneumatic bag which can be inflated and deflated by means of a bulb with a release valve attached and a lower

FIG. 2.—Authors' three-way syringe.

band firmly gripping the wrist. The needle and syringe are fixed to the forearm and kept in place by means of adhesive plaster.

3. *Continuous intravenous infusion.*—Two forms of apparatus are available for this:—

(a) An ordinary intravenous apparatus is used to convey normal saline with 5 per cent. glucose from a flask container to a vein. The lotion need not be heated. A dripper, controlled by a simple thumbscrew, is adjusted to deliver not less than 20, and not more than 30, drops a minute. The limb is with advantage controlled on a suitable splint. The needle, attached to the syringe containing the intravenous anæsthetic, is inserted into the tubing near the vein and the injection given as into the vein (Fig. 1).

(b) The authors' three-way syringe (Fig. 2). A 10 c.cm. syringe with a three-way nozzle is fixed to the forearm with elastic bracelets. With the control in the central position, the barrel of the syringe communicates directly via the needle to the vein. When the control is turned to the left, the lateral feed communicates directly with the needle, and this position is used for continuous saline-glucose infusion as in the preceding method. When the control is turned to the right, the other lateral feed communicates with the barrel, and the syringe can thus be loaded with a further dose of anæsthetic, which may then be injected through the needle by turning the control to the mid-position.

In serious cases a patient can, of course, have blood transfusion throughout the operation with pauses for the anæsthetic administration. Similarly, for any emergency, the syringe can be used for giving stimulants, such as Coramine or Alpha-lobeline; and here an advantage of the apparatus is that only the smallest amount necessary of the drug need be given, since it is accurately measured and reaches the vein direct. We have found the administration of continuous saline-glucose infusion during operation of the utmost importance in some of the "poor risk" cases. Dehydration is combated all the time and shock is largely abolished.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE

SECTION OF SURGERY

At a meeting of this section held on March 4th the chair was taken by Mr. W. SAMPSON HANDLEY, the president, and a discussion on

Intestinal Strangulation

was opened by Mr. IAN AIRD. The mortality of operation for this condition, he said, had fallen to about 40 per cent. by the end of last century and had continued there ever since. The principles of operative treatment could be stated simply: the cause must be removed and non-viable bowel excised. The only question was where lay the dividing line between viable and non-viable bowel. Certain experimental data threw doubt on the wisdom of returning to the abdomen sections of bowel which regained their circulation when the strangulation was released. Gross venous congestion marked the dividing line. While release after a short period improved the circulation, sudden release of a congestion long maintained had a depressor effect on blood pressure. This had been shown by experiments in dogs and cats, which Mr. Aird described. In one case the fall of blood pressure had been followed by death in eight minutes; in others there had been fall of blood pressure after congestion lasting from 6 to 18 hours. Shorter periods of congestion produced a rise in blood pressure when the congestion was suddenly released.

The causes of death in strangulation were three: perforation and peritonitis, loss of blood from the circulation, and absorption of toxic elements from the strangulated bowel. If the loop strangulated were short, the treatment was that of peritonitis; if it were very long, blood transfusion was indicated to replace the blood lost in the loop. In the average medium-length loop another factor must be sought, and the general treatment must be directed towards the toxæmia. Loss of blood in these cases was an important but not a lethal factor. The transudate from the strangulated bowel contained, as a result of bacterial growth in the bowel wall, two toxins. The first was a euglobulin, perhaps related to the complex bacterial toxins; this was the only toxic protein fraction. The non-protein element was a diffusible substance, perhaps histamine, which was present in surprisingly high concentration.

Artificially strangulated loops of small intestine taken from new-born guinea-pigs in which the intestine was sterile could be placed in the peritoneal cavities of adult cats without harm. This strongly suggested that the toxicity of strangulated loops depended on bacterial action. Another series of experiments had shown that the transudate fluid was non-toxic and the seromuscular coat was sterile when the strangulation was only a few hours old. After 18 or 20 hours aerobic and anaerobic bacteria invaded the bowel wall and the transudate became toxic. Animals injected with the euglobulin showed spasticity before death and affection of the liver and spleen post mortem. Certain bacterial exotoxins had the composition of a euglobulin. The success of *B. welchii* preparations in intestinal strangulation had never been explained. The new specific antisera ought to have a field of usefulness in this condition. Death from the non-protein substance was in every case preceded by respiratory embarrassment.

Work on the histamine content of transudate was still in progress. Transudate protein-free filtrate caused an almost identical excitatory effect on guinea-pig ileum to that produced by histamine. The inhibition of rat and stimulation of guinea-pig uterus were similarly comparable. The concentration seemed to be between 1/10,000 and 1/20,000. Proteolytic organisms were present in the bowel wall in enormous quantities and the conditions were ideal for histamine production. Vagopressor substances therefore seemed indicated in treatment.

Dr. DAVID SLOME described experiments by Mr. G. C. Knight and himself. The fluid-loss factor in long-loop strangulations had been determined by weight comparisons. It had varied from 1.4 to 2.2 per cent. of body-weight and so was insufficient to account for death. The initial fall in blood pressure could be attributed to the fluid loss, but the failure to recover and gradual decline leading to death must be attributed to some other factor. Cross-connexion experiments in two animals had shown that strangulation lowered blood pressure, although the fluid loss was all sustained by the other animal. In the non-viable type of strangulation the animals were all dead within 48 hours. The survival-time was definitely related to the severity of the strangulation, but there was no constant relationship between survival-time and amount of fluid loss. In no case was the volume of fluid lost adequate to account for the death. Peritoneal fluid from non-viable loops had been shown to be toxic by transplantation. The toxin by itself produced collapse and death in a normal animal and the blood pressure was always depressed. In viable loops there was no evidence of a toxic fluid at 24 hours. In severe strangulation it might be present after one hour. The depressor substance was readily dialysable through a semi-permeable membrane. The toxin seemed to be formed in the wall of the gut and rapidly passed into the venous blood and into the lumen of the bowel. The rapidity of its formation in high concentration was against a bacterial origin. The depressor action could be demonstrated in thoracic duct fluid also if the lymphatics were not occluded. Relief of venous obstruction allowing return of blood to the circulation did not improve the animal's condition but set free more depressor substance. The substance might be identical with the depressor principle found in normal urine. The urine of cats with strangulated intestine had proved to be depressor.

Mr. G. C. KNIGHT emphasised the significance of the experiments described by Dr. Slome. The toxæmia in strangulation was characterised by early onset and its cause was probably a mixture of depressor substances. Bacterial action only contributed in later stages if at all. Death occurred in the presence of almost normal blood chlorides. Fluid loss was only an accessory. The severity of the strangulation was directly related to the survival period. The length of loop played a part, but not to an extent justifying classification of cases according to length. The parts played by renal function, saline therapy, and the release of the depressor substance into the circulation all required consideration. Attention should perhaps be focused more on the viability of the patient than of the gut. Experiments suggested that death occurred within 96 hours if simple release were practised, while the animals remained alive and well after excision of quite viable loops. Clinical cases had shown similar results.

DISCUSSION

Mr. R. St. L. BROCKMAN pointed out that there was a toxæmia of intestinal obstruction whether the strangulation were severe or not. If the circulation were completely obstructed so that the loop died instantly, no toxic substance was formed in that loop. In the upper part of the intestine isolated loops were toxic; in the ileum they could safely be left. The upper part was more sterile, so bacteria could have little to do with it. Cells in the bowel above a strangulation were living in their own exudates which could not be passed on. As this process mounted the bowel it stopped the action of the glands in the upper part—the liver and pancreas. Patients often died a few days after an operation for relief. In dogs the fatal change had taken place at the moment of stoppage of biliary flow. When the stoppage reached the duodenum life stopped too. There might be in the duodenum some production of vital ferments necessary for the life of the whole organism.

Mr. R. L. HOLT said that the results reported confirmed his own work. He agreed that there were two distinct toxic factors. One appeared within the first hour and was very similar to histamine. It could also be obtained by strangulating omentum and might be the result of tissue breakdown following anoxæmia. After about 20 hours a second protein-toxic factor appeared at the same time as the gut content changed to a black fœtid toxic fluid. The length ordinarily strangulated in a hernia would not produce enough toxin to have a wide general effect; the clinical effect of obstruction was very important. There was also dehydration from vomiting and distension above the strangulation. The amount of fluid withheld from circulation was a most important factor. Long-loop strangulation showed a special clinical picture associated with acute shock and pallor; the combination of toxic absorption and fluid loss were enough to kill the patient. Every loop about which there was the slightest doubt should be resected, and if the patient was in a bad state exteriorisation was a good measure.

Mr. TURNER WARWICK said that complete ligation, in cats had not produced symptoms of obstruction apart from perforation. High obstruction might depend on chemical changes below it as well as above it. The constricted part of the bowel had not received the attention it deserved. A Canadian worker had shown that animals died of toxæmia even if the loop were washed quite free from bacteria. Animals did not die if the distended coil were denervated—which suggested shock as the cause of death.

SECTION OF ORTHOPÆDICS

At a meeting of this section held on March 3rd, under the presidency of Mr. C. MAX PAGE, a discussion on

Fractures in the Region of the Shoulder-joint

was opened by Mr. GEORGE PERKINS, with the remark that it was well occasionally to examine accepted principles of treatment to see how far practice was in accord with theory. The conception that a fracture was a dual injury was not a new one. In past years there had been some who concentrated on treatment of soft parts in fracture cases and appeared almost to forget about the bone. Many had treated the bone and forgotten the soft parts. If there now existed, as he thought there did, a modern school of thought concerning the treatment of fractures, that

school emphasised one fact: that a fracture was a dual injury, and that both bone and soft parts required treatment; that treatment of those parts was of equal importance and should be undertaken simultaneously. Taking the three stages of treatment, (1) reduction, (2) splintage until the bones moved as one piece, (3) protection until consolidation, it was agreed that nothing could be done for the soft parts in stage (1), but in stage (2) the masseuse standing at some distance from the patient made him (a) move all the free joints through their full range; (b) contact all his muscles over the immobilised joint; (c) use his limb, this last being the most important. Thus when stage (3) was reached there was little for the masseuse to do—i.e., she simply had to make the patient move all the joints to their full range, with perhaps a little massage if it was mentally satisfying to the patient. When the bone repair was completed, repair of soft parts also was almost complete. There remained, in the aftermath stage, an occasional manipulation under gas anæsthesia to assist the complete range of movement.

As to the relative importance of treating bone and soft parts, it was granted that bony union was essential, and in cases in which it was difficult to bring about that union the bone treatment was paramount. In fracture of the scaphoid, for instance, it might be necessary to immobilise the wrist-joint for six months in order to bring about the necessary union. But where there was difficulty in restoring mobility to a joint, treatment of soft parts might be the more important. Shoulder and knee had in common the quality that when immobilised, even for a short time, they stiffened; that happened even when there had been no injury or inflammation round the joint, but it was more pronounced in the presence of injury. Some might say this applied to the shoulder-joint only if the arm was held immobilised close to the side, but with that he did not agree. In any fracture about the shoulder-joint, the treatment of soft parts was of far greater importance than the treatment of bone, even allowing that the bone needed treatment. But did the bone need treatment? Injury of bone was divisible into three phases: (1) reduction, (2) splintage until union occurred, (3) protection until consolidation took place. Anatomical reposition of fragments was rarely possible and rarely necessary. The surgeon was content with "good reduction," meaning that when union was completed the alignment of the bone would give rise to no loss of function. In fractures round the shoulder-joint, reduction rarely had to be attempted, often indeed the fractured surfaces were already in good reduction. In the cases in which reduction should be attempted, he considered it could not be done without an open operation. The kind of case needing this was where the shaft of the bone was in front of the head, and the fractured surface was jagged.

Splints were used for two distinct reasons, sometimes for both: (1) to hold the fractured ends still and so prevent them from moving on one another; (2) to hold the fractured ends in good position. If there were muscles inserted into both fragments, they were sufficient to keep the fractured ends still. If no muscle was attached to one or both, splintage was necessary. And sometimes the muscles attached to both fragments could not prevent all movement. But in the shoulder-joint a plexus of muscles was inserted in the neighbourhood of the fracture, and they sufficed, he thought, to hold the fractured ends still. To hold the ends in good position the two essentials were a longitudinal pull to reduce overlap and an upward pull to prevent backward sag. Unless

plaster-of-Paris was used, a splint would not prevent the fractured ends from moving on one another. Where a fracture lay between two hinged joints, as at the knee or ankle, good alignment was essential; but if it was between ball-and-socket joint and hinge joint, mal-alignment was of little moment, because the plane of the ball-and-socket joint would accommodate itself to the plane of the hinge joint. The shoulder was a ball-and-socket joint. Most fractures would unite, whether treated with a splint or without. His contention was that fracture about the shoulder-joint should never be splinted, because (1) reduction was often unnecessary, and if necessary it was usually impossible; (2) the muscles sufficed for holding the fragments immobile; (3) mal-union was of minor importance; (4) treatment of the soft parts was of more importance than treatment of the bone. The bugbear was a stiff and painful shoulder. A patient with a fracture round about the shoulder should be given a sling, and treatment by a masseuse should be commenced at once, preferably in the recumbent position. The patient should move the muscles round the joint, and, as soon as he could be induced to do so, move the joint itself. If unwillingness was shown, he should be taken into hospital or nursing-home and the massage intensified.
